NOTES.

THE POSTMASTER-GENERAL'S annual report, just issued, for the year 1899–1900, is very satisfactory reading so far as the public service of posts and telegraphs is concerned. But in respect of the latter, its financial condition is as discouraging as ever. Summed up briefly, although the telegraph revenue increased by £200,847, the expenditure also increased by no less than £266,916, resulting in a net deficit of £288,438—or £66,569 more than last year's deficit. On this the customary comment is added: "If allowance be made for interest on the capital created for the purchase of the telegraphs, the deficit on the year is raised to £587,326." Every year this painful fact is rubbed in with unsparing reiteration, but without the least attempt at explanation or expectation of amendment. The returns of revenue and expenditure throw little light on the main subject, though the figures are plain enough—so plain indeed that they may be called ugly. For example, whilst the percentage of salaries, &c., to total revenue in the postal service is 44·52, that in the telegraph service is set down as 65·87. A similar comparison between the cost of conveyance of mails and that of telegraph maintenance gives a percentage respectively of 11·00 and 20·39. A still more remarkable contrast would be shown if the percentage of expenditure on the erection of buildings were furnished for the two services. For sites and buildings last year the telegraphs are credited with over £76,000—a sum which, large as it is, is smaller than any set down under those heads ever since 1894-5. One would like to know where and what those sites and buildings are. These items are over and above those charged under the head of "Telegraph Extensions," which alone amounted to £277,133—nearly £50,000 more than the previous year.

AGAINST these financial shortcomings there is abundant evidence that the telegraph service continues to grow both in efficiency and popularity. The number of telegrams forwarded was 90,415,123—an increase of more than three millions over the previous year. A still greater augmentation of business has taken place over the trunk telephone system, the revenue derivable from which was £191,701—an increase of 14·44 per cent. on the preceding year. The offices open for this class of business now number 299, the trunk lines in use consisting of about 68,657 miles of wire; and 7,250 miles of fresh wire are in course of construction. In this connection the POSTMASTER-GENERAL announces that, besides the license granted to the Corporation of Glasgow last March, he anticipates that in several other places municipal exchanges will shortly be established under licenses. As we have animadverted on the expenditure side of the telegraph account, it is only fair to record that upwards of 870 new telegraph offices were opened during the year, and that the cost of repairing the lines after the great gales and snowstorms of February last amounted to £12,000. The number of telegrams classed under the head of "Foreign" was the highest on record, chiefly due to the South African war. With reference to this the POSTMASTER-GENERAL makes graceful mention of the liberality of the Eastern Telegraph Co., who reduced their rates from 4s. to 2s. per word for telegrams to and from HER MAJESTY'S naval and military forces in the field. That this is no small concession is evidenced by the fact that the average daily number of such telegrams is nearly 150. The same privilege has been recently extended to telegrams between South Africa and India and Australasia.

THE Paper by ROBERT LANG, a translation of which we publish to-day, marks an important advance in that theory of electrons which appears likely to triumph all along the line. It is somewhat strange that after the victory of the wave-theory of light, a corpuscular theory of electricity should oust all its rivals. Yet such an occurrence appears about to take place. Ionic theories are masters of the field in electro-chemistry. The ion has proved one of the most useful

Digitized by Google

conceptions of modern physics. It is formed from the molecule by splitting it up into its electro-positive and electro-negative constituents. It promises to be the connecting link between chemistry and electricity, and thus realise the dreams of DAVY and FARADAY. Nobody interested in electrolysis or primary or secondary batteries can nowadays dispense with a thorough knowledge of ionic idiosyncrasies.

BUT when we have no longer to deal with chemical processes, and yet have to account somehow for electric conduction, for cathode rays, Becquerel rays, thermo-electricity, electro-optics, and magnetism, the ion forsakes us, and a new conception has to be introduced. This conception is that of the electron, which stands to the atom in the same relation as the ion does to the molecule. The conception of the electron has been worked out by THOMSON, POYNTING, DRUDE, and others, and may now be said to be fairly concrete. These electrons appear to be able to account for almost every electric phenomenon known. A current in a wire consists of two streams of electrons moving in opposite directions, thus recalling the old two-fluid theory. About 1 atom in every 5,000 is split up into a larger and a smaller portion. The larger portion is positively charged, and the smaller portion negatively. The ratio of the masses is about 9 : 1, and they move about 200 times as fast as the electrolytic ions, the average speed being half a centimetre per second. Their motion produces in the ether the magnetic field with which we are long familiar. When electromagnetic vibrations impinge upon the metal, the electrons are set in violent motion, and in this vibration the incident energy is frittered away—the metal is "opaque." In insulators, the electrons if existing at all, have only a very limited range of vibration. When the metal is an electrode in a vacuum tube, the electrons are projected from the surfaces with velocities comparable to the velocity of light. The negative electrons constitute cathode rays, the positive electrons constitute "canal rays."

IT is when magnetic phenomena, however, are approached that the electron becomes really fascinating. AMPÈRE explained magnetism by the existence of small currents circulating round the molecules of the magnetic metal. These currents, according to ROBERT LANG, are simply convection currents produced by the revolution of the negative electrons round the heavier positive electrons, just like the moon revolves round the earth. Such rotations can only be carried out by electrons having many degrees of freedom, hence magnetism can only be shown to any intensity by substances having spare "valencies" or "links." The explanation of certain chemico-magnetic effects, as well as the Zeeman and thermo-electric effects, follows without much difficulty, and magnetism as a phenomenon distinct from electricity is abolished for ever.

IT remains to follow the electron through all its life history, and to gain some insight into the secret of its charge and motion. LENARD'S production of negative electrons, *vulgo* cathode rays, from a negatively-charged surface by means of ultra-violet light should aid this study considerably. But the greatest help will no doubt be furnished by the phenomena of Becquerel rays, for in this case we have a class of bodies which freely give off negative electrons without being charged at all, and indeed without being supplied with any visible source of energy.

WE are now in the midst of what is sometimes called the "silly season" in the newspaper world. It is a long time, however, since we have seen anything more egregiously silly than the announcement in the *Daily Mail* of last Saturday as to an alleged new discovery by NIKOLA TESLA. We do not know what proportion of the startling announcements frequently made in connection with the name of this electrician is authorised by him, but we hope that for his sake it is a very small one. In the present instance TESLA is reported to have discovered a method of perfectly insulating an electrical conductor by surrounding it with a frozen mixture of water and sawdust in a thin metal tube. This amazing insulator, TESLA is reported to declare, renders possible the transmission of electric power from New York to London. A short while ago TESLA'S schemes were in the ether above the earth's atmosphere. Now they appear to be at the bottom of the Atlantic ocean. We wonder where they will turn up next.

Rathmines Electricity Works.—We are informed that, owing to the indisposition of the Lord-Lieutenant of Ireland, the inaugural ceremony of the new Rathmines electricity works has been postponed from the 24th to the 31st inst.

Electric Light in Pit Sinking.—At an inquest held at St. Helen's on Monday last in connection with an explosion in a colliery, the jury added a rider to their verdict recommending the use of safety lamps or electric lights in pit-sinking.

Lightning and Powder Magazines.—The French Minister of War has invited the Paris Academie des Sciences to advise as to the precautions to be adopted in selecting and planting trees in the neighbourhood of powder magazines in order to protect the magazines from lightning.

Personal.—We note that among the names on the International Board for the Congress on Psychology at the Paris Exhibition are those of Sir William Crookes and Prof. Oliver J. Lodge. It is satisfactory that the physical side of this recondite science is thus safeguarded.

Chefoo-Taku Cable.—The Eastern Extension and Great Northern Telegraph Cos. announce the laying of a submarine cable between Chefoo and Taku, which is now open for traffic, and that arrangements have been made for the early laying of a cable between Chefoo and Shanghai. This will provide submarine telegraphic communication—available for international traffic—entirely independent of the Chinese land-lines, and without any addition to the existing tariffs.

Cable Interruptions and Repairs:—

Wireless Telegraphy at Dover.—The Dover Chamber of Commerce have received promises of support in the action they are taking to get the wireless telegraphy installation connecting the East Goodwin lightship and the shore reinstated. The Chamber have memorialised the Board of Trade and Trinity House, and will bring the question forward at the autumn meeting of the Association of Chambers of Commerce to be held at Paris next month.

A Substitute for Celluloid.—A new substitute for celluloid for engineering and other industrial purposes is described in a German contemporary. The name of this new substitute is "Marloid," and it seems that it is manufactured from untanned leather boiled in oil. The product is said to resemble celluloid in every respect.

The Calcium Carbide Industry in Bavaria.—In a recently issued Consular report from the second secretary in Her Majesty's Legation at Munich, particulars are given of the growing industries in calcium carbide and acetylene in Bavaria. It is stated that a well-known electrical firm in Nuremberg has acquired water-power at Sarpfoss, in Norway, and also at Glommens, and that other firms have acquired similar rights representing from 20,000 H.P. to 40,000 H.P. for the electrical production of calcium carbide. Acetylene gas is largely used in Bavaria for various lighting purposes. The first acetylene gas works for lighting small towns were erected at Hassfurt, a town of 2,500 inhabitants. There are no less than 26 small towns in Germany thus lighted.

A Boiler Record Book.—A publication which steam users whether on a large or small scale, should find of considerable utility has recently been brought out by the National Boiler and General Insurance Co., of Manchester. This consists of a number of strongly-bound ruled pages for entering particulars of boiler plant, the columns being for records of, among other things, cleanings, inspections, repairs, &c. Between the pages are guard slips for gumming in the Insurance Company's reports from time to time, and also any reports of external or working inspections connected with the history of the boiler. The specimen book sent to us contains 52 pages, with room for 20 entries under each column on each page. It is recommended that a separate page be used for each boiler. The price of the book is 4s. 6d. post free.

Electrical Power Transmission in Sweden.—A large power transmission plant at the Trangfors waterfall at Vöstmanland, Sweden, is described in *Engineering*. The Kolböck river there forms a waterfall of about 33ft. in height, and the installation comprises six 800 H.P. radial turbines each having four wheels of 700 mm. diameter on a horizontal shaft, and making 250 revs. per min. The shafts are direct-coupled to the electric generators. The floor of the engine-room is 10ft. above the lower surface of the water, and the shafts of the turbines are located 4ft. above the floor. The water is led to the turbines through three pipes of 8ft. in diameter. Three turbines directly coupled to the exciters also have horizontal axes, and are each of 25 effective H.P. at 560 revs. per min.; they are otherwise of the same construction as the larger ones. The current from all six generators is conveyed to 18 transformers, where the pressure is raised from 800 volts to 14,000 volts. The transmitting line consists of three 6·75mm. copper wires, supported on porcelain insulators attached to poles placed a ta distance of 166ft.; the poles are of a height making the minimum distance from the lowest wire to the ground 27ft.; lightning dischargers are placed at both ends of the line. On reaching the boundaries of the town of Vesteras, a distance of some 14 miles, the pressure is again reduced by a similar battery of transformers, and distributed to the various consumers. The Northern Metal Company head the list of the consumers, their new works requiring no less than 900 H.P., divided amongst 14 motors, varying from 300 H.P. to 3 H.P. capacity. The motors are all of the inductor type, and the large ones are principally used for the working of rolling mills. The works of the General Swedish Electric Company receive 300 H.P. The power station belongs to the Trangfors Power Company. The water power and the site of the station have been leased for a period of 50 years from the owners, the Hallstahammar Co., Ltd.

Profits on Tramway Undertakings.—At the recent meeting of the Tramways and Light Railways Association at the International Tramways and Light Railways Exhibition, Mr. C. H. Gadsby read a Paper with the above title. As an instance of the increase of receipts by a gradual and judicious adoption of more frequent services, he gave a table showing that on a certain steam tramway, by doubling the mileage in seven years, the number of passengers had been more than doubled as had also the gross receipts, while the working expenses had only increased by about 70 per cent. and the resulting net receipts had been multiplied by 8½. The receipts per car mile had increased from 16·5d. to 17·6d., whilst working expenses had fallen from 11·3d. to 9·3d., and the ratio of working expenses from 68 per cent. to 53 per cent. It was not, however, to be expected that the gross receipts could be increased in the same proportion as the mileage, and consequently as a general rule the receipts per car mile were reduced. This fact, he thought, had in many instances led tramway managers to adopt the policy of restricting the mileages in an endeavour to secure high receipts per car mile. Receipts per car mile on British tramways varied from about 7d. to 2s., and he considered that for electric and cable lines "any rise in receipts per car mile above 9d. should be at once checked by an increased mileage." The author illustrated his argument with the following example:—

> Suppose a system running 1,000,000 car miles per annum with gross receipts at 12d. per car mile. The total gross receipts will then be £50,000 per annum; suppose the working expenses are at 60 per cent., and therefore amount to £30,000 per annum; the net receipts will be £20,000 per annum. Let, now, the mileage be increased 20 per cent., to 1,200,000 car miles per annum, and suppose the total gross receipts increase only at the less ratio of 15 per cent., and that, in consequence of standing and managerial charges being spread over a greater mileage, the working expenses increase only 15 per cent. also. We shall then have the total gross receipts, £57,500 per annum; the total working expenses, £34,500 per annum; and the net receipts, £23,000 per annum. In this case the gross receipts per car mile work out at 11½d.; that is by increasing the mileage 20 per cent. we have reduced the receipts per car mile from 12d. to 11½d., but have at the same time made an extra £3,000 per annum clear profit.

A table was also included in the Paper showing the working expenses for eight (unnamed) electric tramways in this country, some worked by companies, others by municipal owners, but all on the overhead trolley system. The car mileages in one year varied from 135,740 to 1,160,279, the aggregate being 3,016,761, and the average operating expenses in pence per car mile as follows: Maintenance of permanent way, 0·765; motive power, 1·38; repairs of general plant, 0·305; repairs of cars, 0·576; traffic expenses, 2·67; all other expenses, 1·15; total, 6·896. The cost of motive power was, Mr. Gadsby pointed out, much lower than with horses or steam, being only 1·36d. per car mile, or, including engine and dynamo repairs, 1·685d. Car repairs per car mile were about the same as for horse or steam traction, in spite of the repairs of motors and electrical equipments being included, probably because, although the expenditure on each electric car was greater, the daily mileage run by an electric car was also greater. The item for traffic, consisting chiefly of drivers' and conductors' wages, was much the same for all three systems. The total expenses of 6·8d. per car mile was somewhat higher than was generally expected with electric traction, owing to the inclusion in the list of a number of small undertakings recently started. He expected from the many larger municipal undertakings an average total expense between 5d. and 6d. per car mile. On the line in the table with the mileage of 1,160,279, in fact, the total costs were but 5·8d. per car mile, on one with the next largest car mileage of 564,389 they were 5·75d., whilst at Leeds, which was not included in the list, the total working expenses were reported well under 5d. per car mile. Another table giving in detail the operating expenses for 23 American electric roads agreed closely with the results of English working, notwithstanding the very different conditions. Finally, the following table was given of the sizes and number of units of generating plant the author has found suitable for various number of cars in service on electric lines under English conditions:—

No. of cars	5	10	15	20	25	30	35	40	45	50
No. of sets of generating plant including reserve	2	2	2	2	2	2	3	3	3	3
Power of each set in kw.	60	125	175	225	275	300	175	200	200	225

No. of cars	55	60	65	70	75	80	85	90	95	100
No. of sets of generating plant including reserve	3	3	3	3	3	3	3	3	3	3
Power of each set in kw.	250	250	275	275	300	300	325	325	350	350

SUNDERLAND CORPORATION ELECTRIC TRAMWAYS.

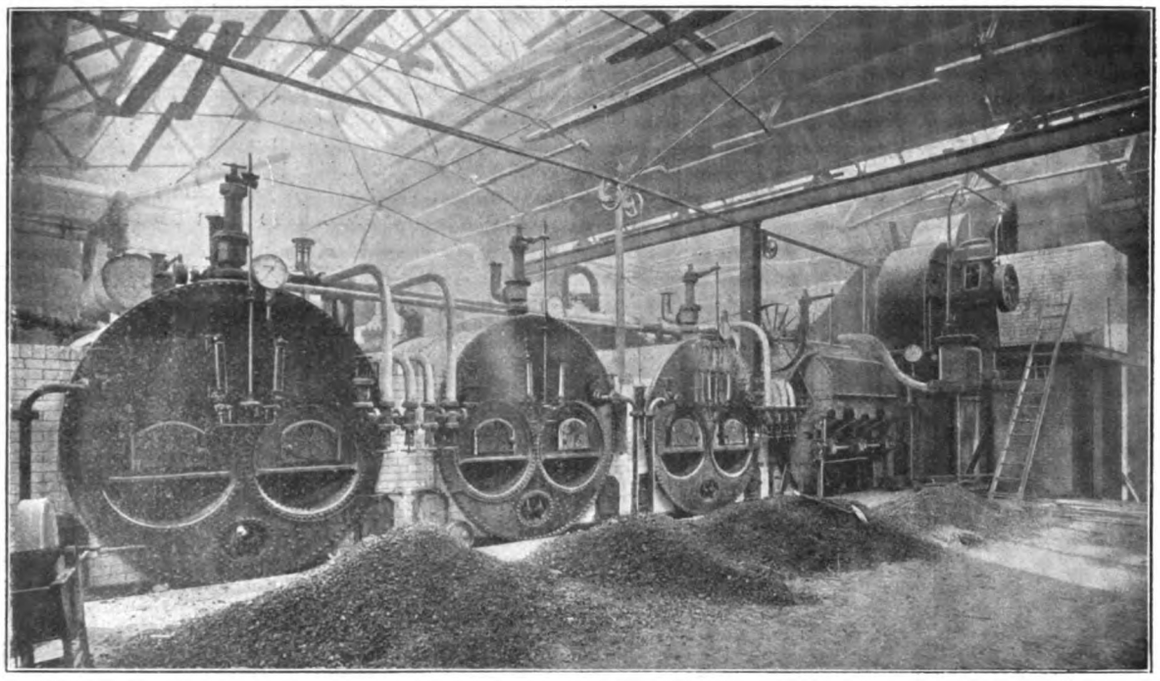
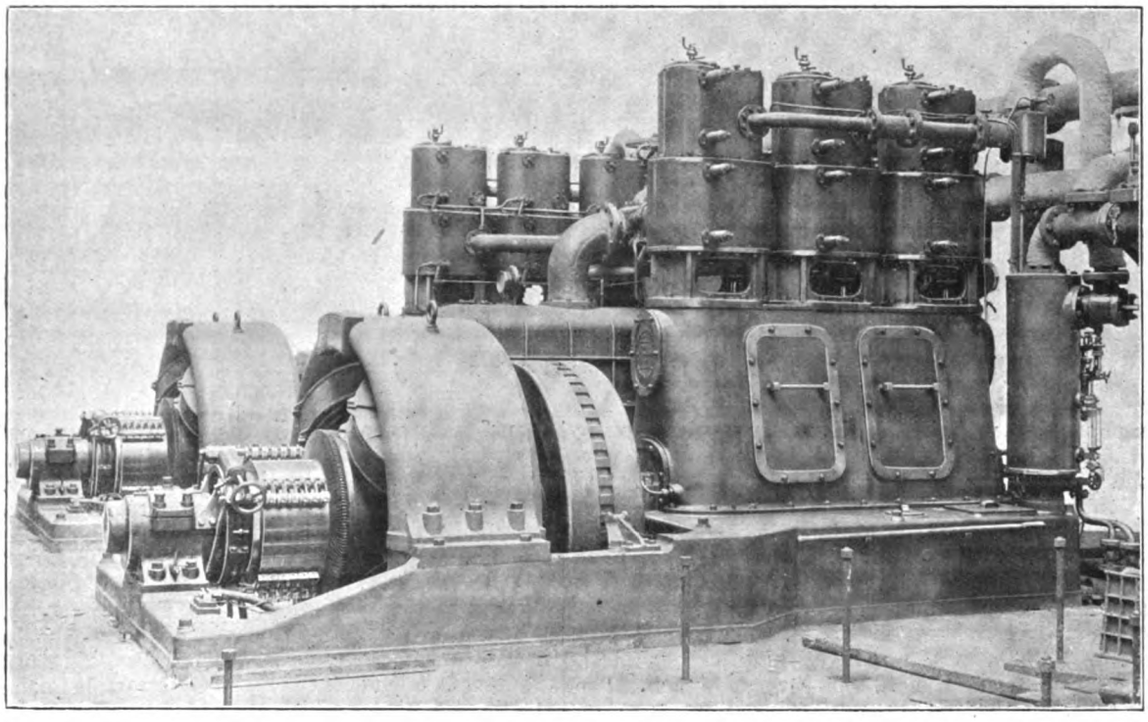
The nucleus of what will ultimately be an extensive system of municipal electric tramways was formed on Wednesday, the 15th inst., at Sunderland by the opening of some 12·5 miles of electrically-equipped tramway track. Sunderland is an important seaport town situated at the mouth of the River Wear in Durham. It possesses an extensive shipping trade in coal and timber, besides numerous engineering and other industries. The tramway system, when completed as now projected, will connect a large number of busy thoroughfares in the centre of the town and link these with the suburban and seaside districts surrounding the town. Tramways have been in existence in Sunderland since 1879, when the Sunderland Tramways Co. commenced running a few horse cars on a portion of the existing system. The company having acquired powers in 1878 it will be seen that the local authority received powers to compulsorily take over the tramways in 1899. Accordingly in 1898 the Corporation commenced to pay serious attention to the question of municipalising the tramways. A tramways committee was formed and a deputation, including the Mayor of Sunderland and the Corporation electrical engineer, Mr. J. F. C. Snell, visited Hamburg, Brussels, and other cities on a tour of inspection of electrical systems of traction. At the conclusion of this tour the deputation unanimously supported Mr. Snell's recommenda-



SUNDERLAND: INTERIOR OF BOILER HOUSE.



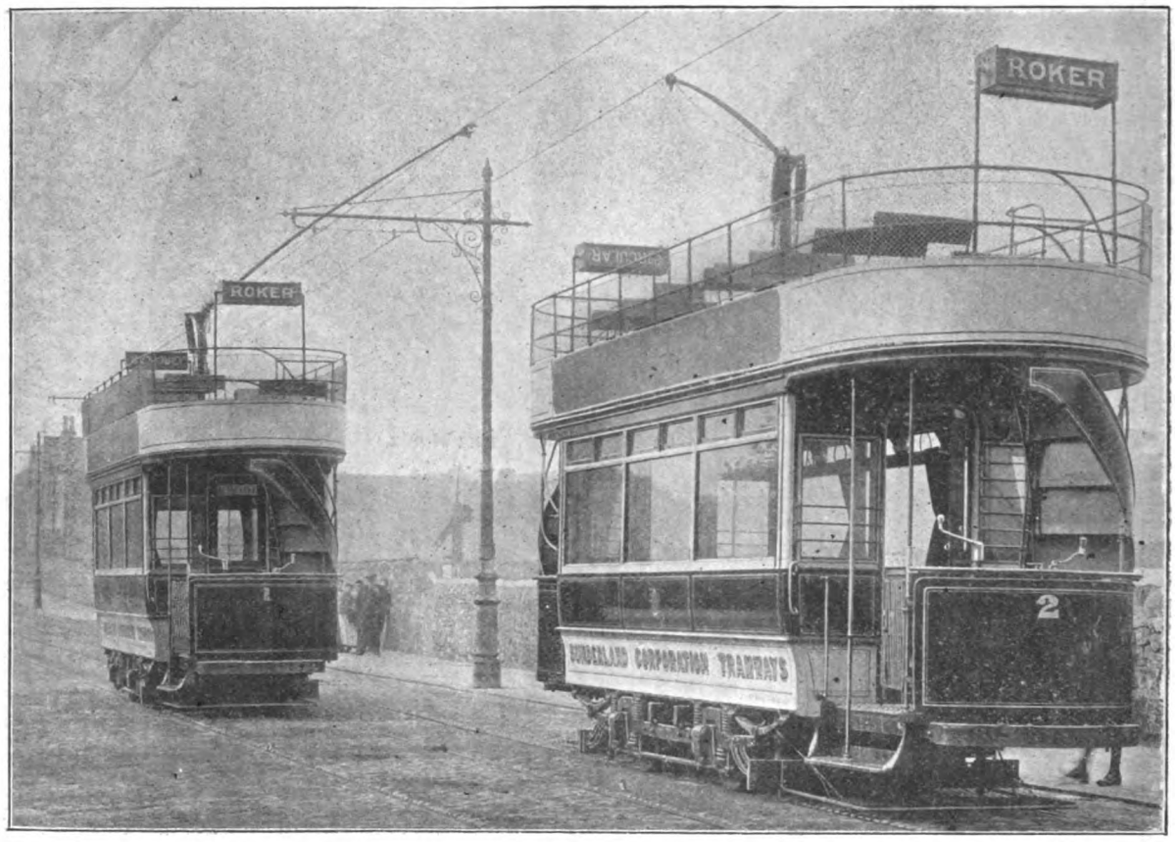
SUNDERLAND: TWO OF THE TRACTION GENERATORS.

Digitized by Google

tion to adopt the overhead trolley system, and plans for carrying out this were put in hand. On September 21st of that year the Council formally accepted the proposals of the Tramways committee, and it was decided to seek the necessary powers in a bill then being drafted. The Sunderland Corporation Act, 1899, granted, among other things, powers to work electrically 23 miles of single track extending over 12½ miles of route. The act allowed a period of five years for the completion of the scheme, but it was decided to proceed immediately with about half of the total mileage, the greater part of this portion of the scheme having now been completed and the remainder being nearly completed. It should be mentioned that at the time of the compulsory purchase of the tramways the capital of the company stood at £74,000 paid up, and that the entire undertaking was acquired by the Corporation for £35,000, the discrepancy being explained by the immortal section 43 of the Tramways Act.

between each pole. The track bonds, supplied by Messrs. Askham Bros. and Wilson, are of crucible cast steel. The crossings are set up with the 7in. track rails, and are set at 1 in 8. The draining of the track has been carried out by cutting the rail and placing drain boxes connected by pipes and intercepting chambers to the nearest gulley. The track has been paved over a considerable length with creosoted Scotch fir laid direct on concrete floated up to level and pitch grouted. The remaining portions of the track are paved with Norwegian or Aberdeen 6in. by 4in. granite setts laid on a 1in. bed of sand, and pitch grouted.

The entire contract for the equipment of the track has been carried out by Messrs. Dick, Kerr & Co. Span wires with rosettes have been used in one of the principal streets, viz., Fawcett-street. In North Bridge-street and Roker-avenue centre bracket poles have been used, and for the remaining portion of the track short side poles are employed. Where bracket poles have been used the trolley wires have



SUNDERLAND: CARS AND SIDE-POLE CONSTRUCTION.

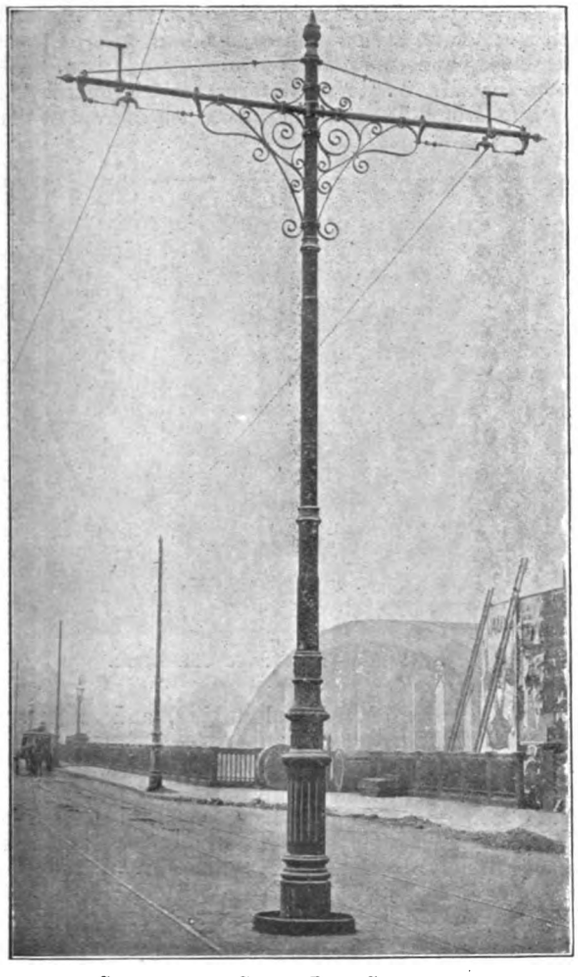
The accompanying map, Fig. 1, shows the routes already working, those nearing completion, and the remaining portions of the system which come under the scheme embodied in the Act of 1899. The tramways now running extend from the seaside suburb of Roker through the town to Christchurch. In converting from horse to electric traction the track has been entirely reconstructed, more solid foundations and a heavier type of rail having been laid down. The general section of the track is shown in Fig. 2. The track is laid throughout with 96lb. girder rails of high carbon steel, possessing a tensile strength of 46 tons per square inch. The rails are in 30ft. lengths. It is regrettable that owing to the inability at the time to obtain immediate delivery of English rails, a German firm—viz., the Phœnix Rail Co., of Ruhrort—were engaged to supply these rails. The fish-plates are of 64lb. steel, and the sole-plate weighs 34lb. The rails are bedded on to 6in. of 6 to 1 concrete, packed up with 3 to 1 cement mortar. The tie rods are placed 8ft. apart, and are of 2in. by ⅜in. wrought iron. The joints are bonded with double 000 Columbia bonds, the cross bonds being placed opposite to each pole, and the track bonds

been flexibly suspended by the fiddle bow suspension now so deservedly popular. The trolley wire is of No. 0 S.W.G. gauge and is duplicate throughout. The poles, made by Messrs. Stewart and Menzies, are three-section steel poles of three descriptions—viz. (1) poles tested for 1,000lb. strain, (2) poles for 1,500lb. strain, and (3) poles for 2,000lb. strain. The brackets are of Mannesmann tubes. The span wires throughout are of 7/13 galvanised steel wire. It should be mentioned that the details of the bracket work instead of being of cast-iron are of gunmetal, painted.

Messrs. Callender's Cable and Construction Co. have supplied the traction cables, which are laid throughout on the "drawn-in" system. This company has also supplied the section pillars. The cables are laid in Sykes' earthenware conduits placed in the clear-way between the tracks as shown in Fig. 2. There are four traction feeders—viz., one of 0·35 sq. in. section divided into two branches each of 0·122 sq. in. section and three feeders each starting with 0·2 sq. in. section, and reducing to 0·122 sq. in. section. The line wires are of 19/18 lead-covered cable. The return cables are laid in the following manner: There are first two cables of 0·4 sq. in.

Digitized by Google

section, connecting the power station to the nearest point on the track, and these cables are connected to the track as follows: The track is crossed by four 000 bonds which are clamped together in a draw-box in the clear-way; the cables are connected to these clamps by means of thimbles. In addition to these return cables one point near one terminus is brought back to a negative booster at the station through a 0·8in. cable. Another point near the other terminus is brought back in the same manner through a 0·25 sq. in. cable. The negative boosters are made self-regulating by carrying the outgoing current through the series windings of the boosters, thus making the boosted negative volts proportional to the load on the traction generators. For the telephone and test leads three-core and four-core cables have been laid. The draw-boxes which, as shown in Fig. 2, are



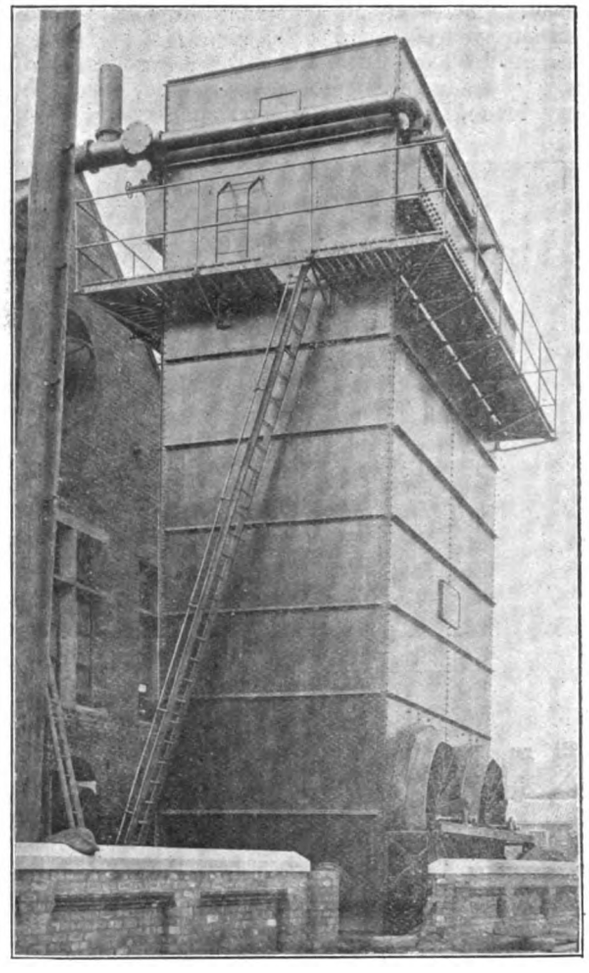
SUNDERLAND: CENTRE-POLE CONSTRUCTION.

placed in the clear-way between the tracks, are of cast-iron with heavy cast-iron covers, the spaces being filled with beech blocks. They are built on 9in. walls, cement rendered.

There will ultimately be 70 cars running on the tramways, and of these 26 are on order, but only eight have at present been delivered. The cars have been built at the Electric Railway and Tramway Carriage Works, Preston, and have been electrically equipped at the neighbouring works of the English Electric Manufacturing Co. Those at present delivered are equipped with Brill trucks and are double-decked, having a carrying capacity of 56 passengers. It is, however, intended to use six double bogey trucks, also eight single deck trucks for one of the routes on which there is a low over-bridge. On some of the cars "Standard" air brakes have been fitted, and all the cars are fitted with emergency electric brakes besides the usual ratchet hand-brake. A striking and useful feature of the cars, as shown in the illustration, is the illuminated destination boxes carried at each end. These boxes are fitted with three 8 c.p. lamps which render them conspicuous after dark. The headlight on the cars is not electric but oil, as owing to the darkness of some of the streets traversed it was thought desirable not to use electricity in case of a breakdown. The trolley standard is placed in the centre of the car deck and carries a swivel type of arm. The greatest overhanging, however, is only 7ft. The trolley wire has a 22ft. clearance from the ground.

The electric car sheds at present have been built out of part of the old horse sheds, and the work of reconstruction is still going on. At present there are four tracks, each with a continuous inspection pit. The present capacity of the sheds is about 20 cars.

Electric power for these tramways is being supplied from the Corporation electric supply station, which has been in operation since 1896. The traction plant, however, is distinct from



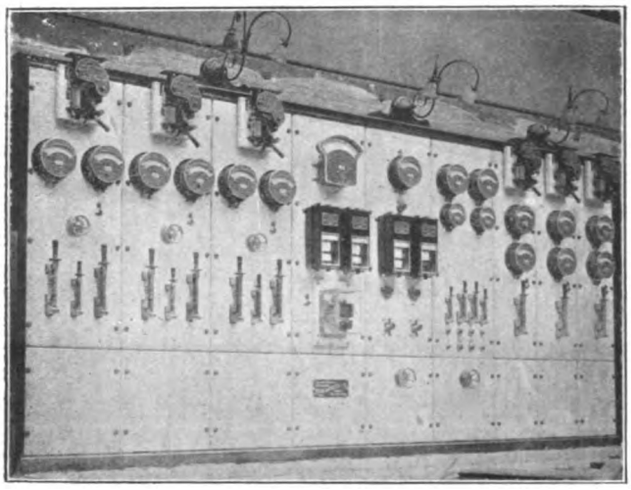
SUNDERLAND: CONDENSER COOLING TOWER.

the lighting plant with the exception that the new boilers are interconnected with the old boilers originally installed for lighting purposes. The new steam generating plant includes four Galloway boilers, each 28ft. by 8ft. 6in., raising steam at 130lb. pressure. There are also two Green's economisers each with 286 tubes and two steam-driven "Buffalo" draught fans, each 72in. in diameter for producing the induced draught for the entire boiler plant. The boilers are fed from two Weir direct-thrust vertical steam-feed pumps. The steam ranges are of 6in. lap-welded steel. At present the boilers are fired by hand with cheap slack fuel, but it is intended to carry out a system of mechanical coal conveyance and stoking, two or three types of mechanical stokers being about to be introduced for purposes of trial. The chimney is but 45ft. in height from the base level, and on this account mechanical induced draught has been adopted. It is found that with the existing arrangements for draught the highly bituminous slack fuel employed can be burned without producing smoke.

Within the machinery room the lighting and traction sets are arranged in one long row, each set being placed

Digitized by Google

transversely across the length of a somewhat narrow room. The utmost use has been made of the small space available. At one end of the room is the original lighting switchboard, while facing the sets along one side of the room near the centre is the new tramway switchboard erected on a spacious platform. The lighting sets comprise the following items—viz. (1) two Holmes-Willans direct-coupled two-crank 60 H.P. balancers; (2) three Belliss-Silvertown direct-coupled two-crank 200 H.P. generators; (3) two Belliss-Parker direct-coupled two-crank 200 H.P. generators; (4) one Belliss-Holmes direct-coupled three-crank four-pole 450 H.P. generator; (5) one Belliss-Sunderland Forge direct-coupled three-crank four-pole 450 H.P. generator. All these generators run at 220 volts. The traction sets are four in number, each consisting of a Belliss-Sunderland Forge three-crank four-pole 450 H.P. direct-coupled set, running at from 500 volts to 550 volts according to the load. These four sets are coupled in pairs to two Wheeler the surface condensers, the condenser foreach pair being erected immediately between them. The tramway switchboard, which is of a plain but serviceable construction, was erected by Messrs. Moon, Loughlin & Co., of Manchester.



SUNDERLAND: TRAMWAY SWITCHBOARD.

The following is a list of the contractors, sub-contractors, and manufacturers who have supplied plant for this tramway undertaking:—

Entire equipment of track	Dick, Kerr & Co.
Cables	Callender's Cable & Construction Co.
Traction generating sets, condensers, pumps, and cooling tower	Sunderland Forge & Engineering Co.
Switchboard	Moon, Loughlin & Co.
Steam and other pipe work	Wearmouth Foundry Co.
Steam engines	Bellias and Morcom.
Condenser, &c.	Wheeler Cond. and Engineering Co.
Feed pumps	G. & J. Weir.
Boilers	Galloways.
Economisers	E. Green & Son.
Cars	Elec. Rail and Tram. Carriage Wks.
Cars, motors, &c.	English Electric Manufacturing Co.
Conduits	Albion Clay Co.
Rails	Phœnix Rail Co. (Germany).
Points	Askham Bros. and Wilson.
Poles	Stewart and Menzies.
Bracket tubes	Mannesmann Tube Co.
Buildings	T. P. Shafcoe.

For the section of the tramways now completed or nearing completion the following are the items of expenditure:—

Four boilers, &c.	£4,490
Steam and other piping	2,080
Generators, condensers, cooling plant, &c.	14,190
Switchboard	685
Draught fans (including erection)	870
Buildings	44,915
12·8 miles of permanent way	96,000
Overhead equipment (including cables)	14,000
26 cars and spares	15,800
Car shed alterations	5,200
Approximate total..	£158,230

Since the inauguration of a section of these tramways on the 15th inst. the public has shown in a very practical way its appreciation of the facilities afforded. On the first half-day 14,747 people were carried, the receipts amounting to £67 and on the next day 16,900 passengers were carried, the receipts being £74. The fares have been reduced 40 per cent., being now 2d. for the entire distance with 1d. sectional fares. No small share in the success of this undertaking must be attributed to the energetic and able Corporation electrical engineer, Mr. John F. C. Snell, and it is greatly to his credit that the undertaking has been carried out in the short space of time since it was decided to electrically equip the line. Mr. Edward White, the station superintendent, has ably assisted Mr. Snell in supervising the erection of all the plant at the station, and Mr. J. R. Crisp has acted as resident inspector of the permanent way and electrical equipment. Mr. G. L. Andrews, B.Sc., is the tramway superintendent in charge of the sheds, rolling stock, and completed portions of the line. We may mention that Mr. W. Morrison, formerly the general manager of the Sunderland Tramways Co., was transferred at the time

SUNDERLAND: ELECTRIC CAR SHEDS.

of the taking over of the undertaking, and is now traffic manager for the Corporation.

A scheme is now being developed, and will shortly be brought before the Sunderland Council, for the erection of a much larger power station and car sheds, to enable the electric tramway and supply systems of Sunderland to be still more extensively developed. We hope at an early date to present our readers with further particulars of this scheme, which we trust will be brought to maturity.

In conclusion, we acknowledge our indebtedness and express our thanks to Mr. John F. C. Snell for his courtesy during our recent visit to the tramway system and for the assistance he has rendered us in the preparation of this article.

Wireless Telegraphy on Borkum Island.—Her Majesty's Consul-General at Hamburg reports that a station for wireless telegraphy has been erected by the North German Lloyd Steamship Co. of Bremen on the Island of Borkum, off the north-western coast of Germany, for the purpose of communicating both with passing vessels and with the mainland. Experiments for testing the capabilities of the apparatus at the Borkum station have been proceeding during the last few months, and it is stated that, owing more especially to improvements made in the apparatus by the North German Lloyd, the results have been very satisfactory. Experiments made lately by the express steamer of that company, the "Kaiser Wilhelm der Grosse," resulted in quite readable messages being sent from that vessel to Borkum, and received on board from Borkum, at a distance of 40 nautical miles; whilst it is stated that messages which were fairly clear were received at the Borkum station from on board the steamer even at a distance of 50 nautical miles.

THE PARIS EXHIBITION.—IV.*

(BY OUR SPECIAL CORRESPONDENT.)

The generating sets built by the French firms offer, as a whole, a strange contrast to the typical English ones already described, and, it must be said, to the detriment of the former.

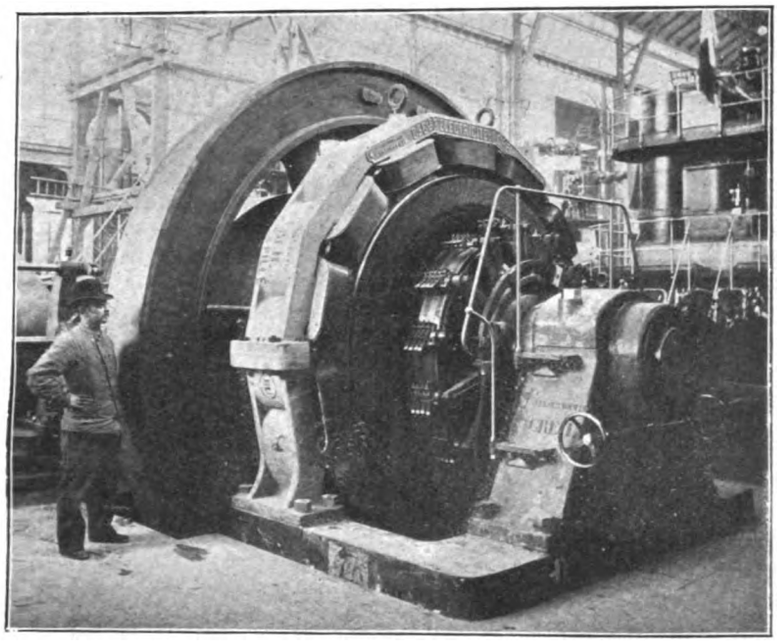

FIG. 12.—700KW. DAYDÉ PILLÉ DYNAMO.

Instead of the compact fast-speed engines, we find slow-running mill engines employed to a large extent, and in many cases single-cylinder machines, some of the latter being used even for alternators. Of course, as the exhibition alternators are not paralleled, an even turning moment is not so essential, but one looks to an exhibition of this sort to find an indication of the typical practice of the country. I will, however, first describe some of the continuous-current sets, and will commence with the 700kw. Daydé et Pillé dynamo (manufactured by the Compagnie Générale d'Electricité de Creil), which is driven by a 1,000 H.P. single-cylinder Weyher et Richmond engine of peculiar construction. The dynamo, which may be regarded as a good example of French manufacture, is illustrated in Fig. 12. It is a shunt machine, designed for 700kw.

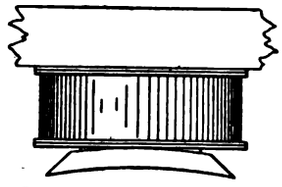

FIG. 13.—POLE-PIECE OF DAYDÉ PILLÉ DYNAMO.
(One-twentieth size.)

at 250 volts. The field magnets consist of a mild steel ring, from which 14 magnet cores radiate inwards. The shape of the pole-pieces, which are of forged iron, and are not in one piece with the cores of the magnets, is shown in Fig. 13. The armature, 2,250mm. (7ft. 4½in.) diameter and 510mm. (1ft. 8in.) wide, is formed of discs insulated from one another by paper and carried on a cast-iron spider. Copper cable of rectangular section is employed for the winding, and the armature being a smooth surface one, the windings are held in place by binding wire and by distance-pieces fixed in slots in the core. The end connections are made by curved strips, wood being employed to maintain these in position. The commutator has a diameter of 1,600mm. (5ft. 3in.) and a useful width of 185mm. (7¼in.), and the brushes, of which there are four per pole, or 56 in all, each oppose two surfaces—copper and carbon—to it. The efficiency of the machine at full load is stated to be 94 per cent.

As already noted, the engine is of the single-cylinder type, its valve gear being its most interesting feature. This is placed at the end of the cylinder and is shown in Fig. 15, Fig. 14 being a general view of the engine with the gear hidden. The cylinder diameter is 1,050mm. (3ft. 5⅜in.), the stroke 1 metre (3ft. 3⅜in.), the speed 120 revs. per min., and the steam pressure 7kg. per square centimetre (100lb. per square inch), a reducing valve being employed to reduce down from the 10kg. per square inch (142lb. per square inch) pressure of the steam mains. The general characteristics of the carcase of the engine are apparent in Fig. 14 and do not need enumeration. The cylinder casting is in three parts. Of these the middle one may be considered the cylinder proper and is steam-jacketed, while the other two contain the admission and exhaust steam ports, the first-mentioned of which is also jacketed. The admission and exhaust valves are flat and self-closing and are very light; they bear directly upon orifices in the ends of the cylinder, this disposition diminishing clearance to a minimum. They have the shape of sectors of circles, and move backwards and forwards along a circular path in their own plane. The admission valves are controlled by wiper shafts actuating a trip motion regulated by the governor. The exhaust valves are actuated by a link motion, the link being partly straight and partly curved. As the slide moves along the straight part of the link, the exhaust valve opens and then quickly closes; when the slide is on the curved extremity of the link, the lever fixed to its end and controlling

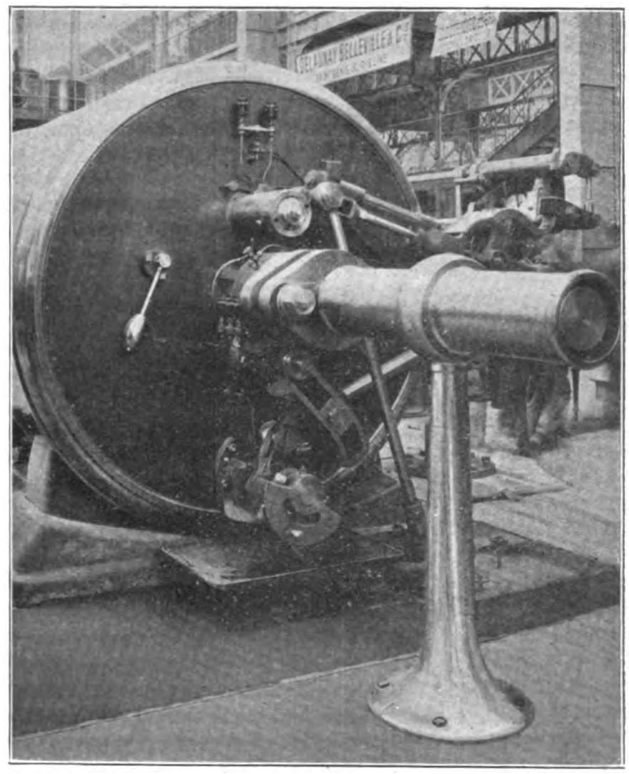

FIG. 15.—DETAIL OF VALVE GEAR OF WEYHER AND RICHEMOND 1,000H.P. SINGLE-CYLINDER ENGINE.

the valve is at rest. The various parts of the valve gear and its action can be traced out on Fig. 15.

The engine is provided with a heavy crank-shaft governor, actuating directly the trip motion. A special knock-off is

* Previous articles appeared in *The Electrician* of July 20 27, and August 3.

Digitized by Google

provided in addition, which shuts off steam in the event of the main governor being deranged. The flywheel weighs 30 tons. The barring gear, another important necessity in a single-cylinder engine, is seen in Fig. 14.

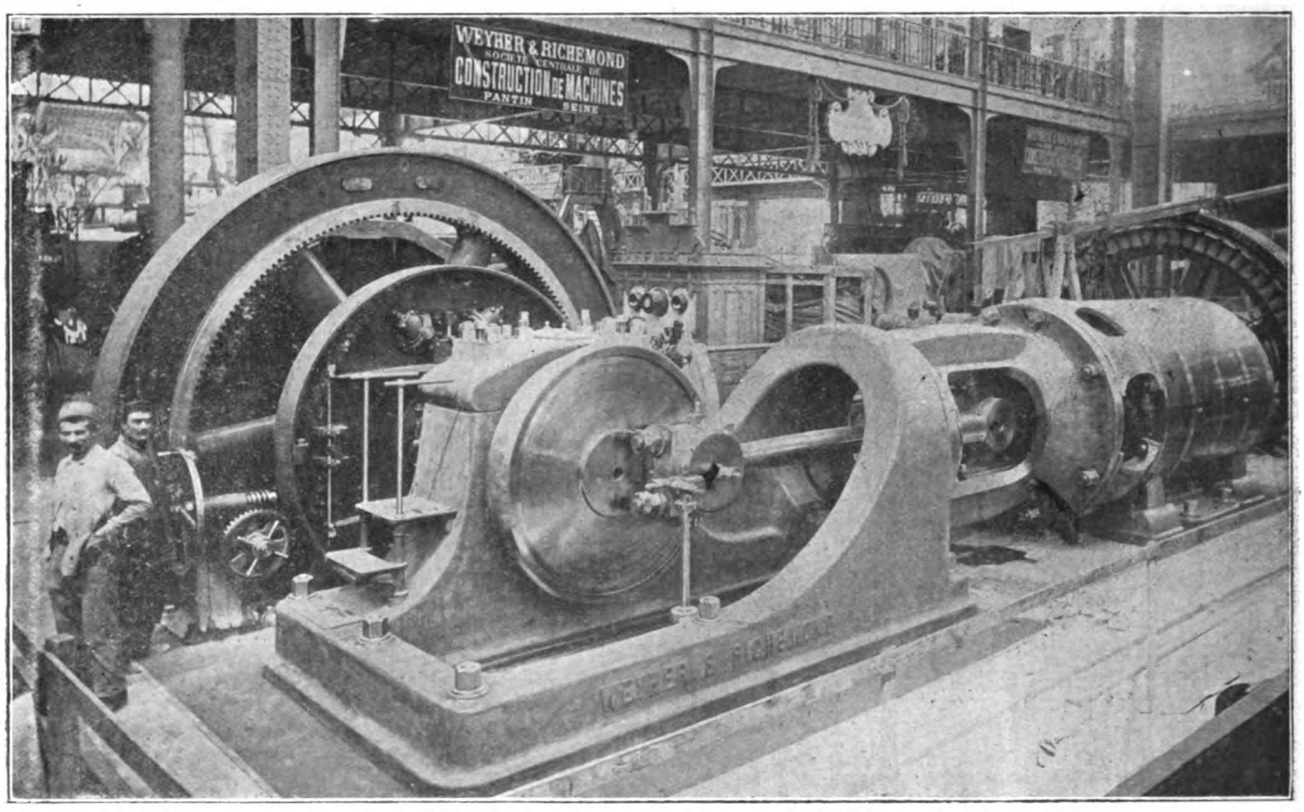

FIG. 14.—1,000H.P. SINGLE-CYLINDER ENGINE BY WEYHER AND RICHEMOND.

In the generating set of the Société Alsacienne de Constructions Mécaniques, it is the dynamo that presents the most interesting features, although the design is not a new one. The machine is destined for the supply station of the Compagnie Parisienne de l'Air Comprimé on the Quai de Jemappes, where several other machines, similar in design and size have been erected during the last few years. The striking peculiarities are the employment of a Gramme ring for the armature which revolves past stationary field magnet poles placed within it, the outer side of the ring serving as commutator. In fact, at a first glance the machine resembles a huge revolving commutator, and one may wonder why it need be driven by the large vertical cross-compound engine which is coupled to it. Figs. 16 to 19 show the general arrangement of the engine and dynamo, and from the first of these the construction of the combined armature and commutator is evident. The field magnets are 12-polar, and are made up of a steel casting with wrought-iron pole-pieces each of which is fitted with a coil wound on a sheet-iron former. The field magnet casting is bolted to the bed plate of the

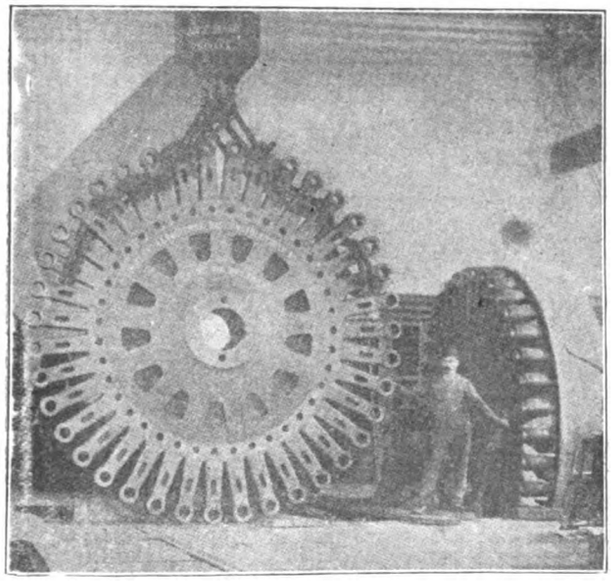

FIG. 20.—CASTING SUPPORTING THE ARMATURE OF SOCIÉTÉ ALSACIENNE DYNAMO.

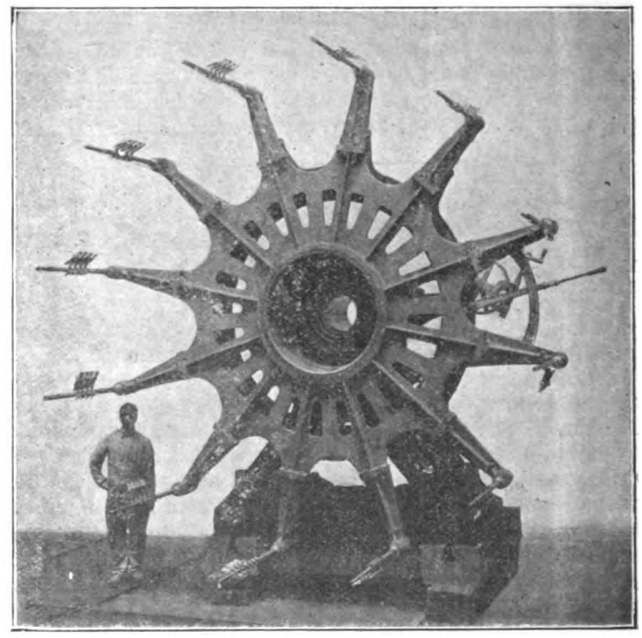

FIG. 21.—BRUSH-HOLDER CASTING OF SOCIÉTÉ ALSACIENNE DYNAMO.

Digitized by Google

engine. The armature, as is seen, is of large dimensions, and is formed of an annular core of steel stampings, the whole being maintained by a star-shaped casting (Fig. 20) with 89 arms, which is keyed to the main shaft of the engine. The diameter of this casting is about 18ft., and it weighs 7½ tons. Each arm of this carries a horizontal steel bar fitted with a bronze sleeve, which serves to support the core discs, and at the same time regulates the distance between the core and the plane of the star-shaped casting. These bars are prepared is insulated with a layer of asbestos paper, and is then wound with paper-insulated copper bars of rectangular section, some U-shaped and an equal number of straight ones. The U-shaped bars are placed from inside across the core and the straight ones are on the outside and form the commutator bars, connecting the right-hand of one U to the left-hand of the next to form a completely closed Gramme ring. The 12 brushes are carried on the casting shown in Fig. 21 —an enormous brush-holder, for its diameter is 14ft. 9in.—

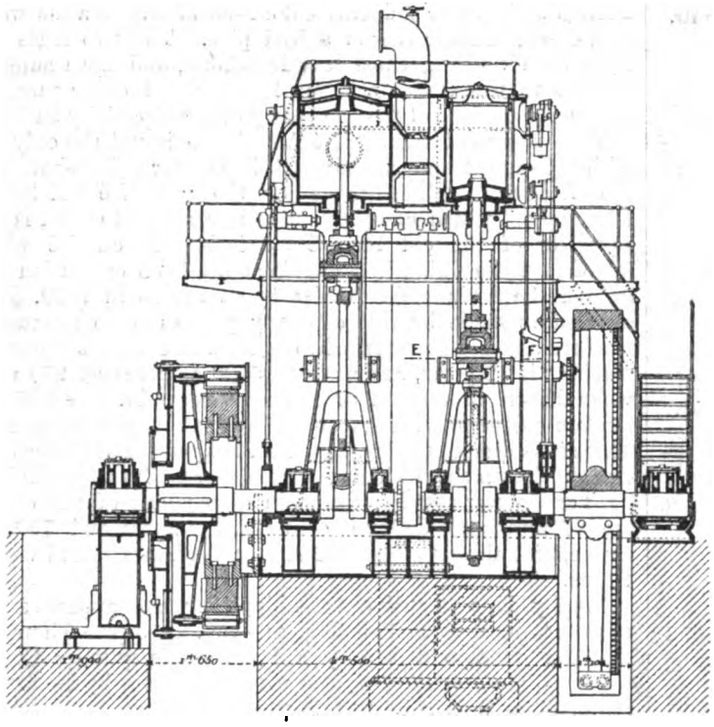

Fig. 16.—Sectional Elevation of Dynamo and Engine (section on A B).

Continuous-Current Generating Set built by the Société Alsacienne de Constructions Mécaniques.
700kw. at 500–600 volts; 60 revs. per min.

insulated from the casting itself by means of insulated tubes and washers. The core is formed of stampings of soft steel 0·5mm. thick, these bars passing through holes in the stamping. Thirteen core sectors make up the complete annulus, being placed end to end, the joints in one layer being covered by the metal of the next. The core, when built up on the support in this way and with paper between the layers, undergoes a strong compression and is held together with bronze nuts and washers. On the right of Fig. 20, in the background, is seen a completed armature core ready for winding. The core thus and the rods carrying the brush-holders proper are mounted on ebonite sleeves on rods projecting from this spider in a similar way to those from the armature spider. A handwheel in connection with worm gearing turns the whole casting to adjust the brushes. The data for a similar machine running in the Quai de Jemappes station, given on next page, are of interest.

The engine valve gear is of the Wolf-Corliss type. The cylinders are jacketed, the jacket of the high-pressure cylinder receiving steam direct from the boiler, that of the low-pressure

cylinder, however, constituting the receiver. The cylinder diameters are 85cm. and 185cm., and the stroke 120cm., and the general design is seen in Figs. 16 to 19. There is a ball governor acting on the cut-off of the high-pressure cylinder. The flywheel is on the opposite side to the dynamo. Its diameter is 5·7 metres, and it weighs 31 tons.

A generating set consisting of an engine made by MM. Crepelle & Garaud, and a dynamo by the firm of Décauville Aîné is another type of French design. The dynamo is 10-polar, and its field magnet poles project inwards from a polygonal frame, the coils being wound on the sides of the polygon. This may be described as of the Thury pattern. The engine is a horizontal cross-compound Corliss machine, rated at 1,200 H.P. Its flywheel is placed between the two cylinders, and a 250-volt 1,800-ampere dynamo is placed on each side of the flywheel. Considering its output, the machine appears rather bulky. Providing current for the exhibition supply, the two dynamos are usually connected in series, but they can be put in parallel if desired. A drum winding is employed on a smooth core.

Two small Bréguet dynamos driven by de Laval steam turbines have been placed among the larger French generating sets, and do not seem to attract as much attention as they deserve. This is probably because of their small size, combined with the fact that their working parts are not visible; and, moreover, the gentlemen attending the French exhibits are not always as attentive in answering questions as they might be. The de Laval steam turbine is an impulse wheel, unlike the Parsons' which is a reaction turbine. Steam is simply directed against the blades of the wheel by nozzles, being allowed to expand on its way from the throttle valve to the directing nozzles. Thus the speed at which the wheel revolves is very great, varying from 7,500 to 30,000 revs. per min. (representing a peripheral speed of from 175 to 400 metres per second) according to the type and size of the turbine. The specimens in operation at the exhibition have wheels of about 70cm. diameter, making about 7,500 revs. per min. These high speeds necessitate the employment of a double helical gearing between the turbine and the dynamo shaft, this gearing being enclosed in a cast-iron case which forms part of the main casting of the engine.

Two generating sets of still smaller capacity may also be mentioned in passing—viz., two 60 H.P. Charon gas engines belted to continuous-current dynamos made by the Compagnie Générale Electrique of Nancy. These each generate current at 250 volts, and are employed together with the larger 250-volt machines to supply make-up current to one side of the three-wire network. They have proved of great service on an emergency, as, for instance, when the water supply to the French boilers was suddenly cut off one afternoon a few weeks ago, due to the bursting of a feed pipe. The two little sets have been running since last December, and have supplied current to the cranes and for lighting and other purposes during the erection of the machinery in the electricity building.

The dynamo of the Société Alsacienne is not the only one with a Gramme ring armature, this honour being shared by the Labour machine made by the "Société l'Eclairage Electrique," which company, it is interesting to note, is the successor of the old Société Générale d'Electricité which introduced the Jablochoff candle at the 1878 exhibition and lighted the Avénue de l'Opéra by its means in 1879. The alternators made by this company possess some interesting features and will be returned to later. The continuous-current machine is 12-polar, and generates 800 amperes at 250 volts when driven at a speed of 120 revs. per min. by a 300 H.P. tandem compound Biétrix engine with Collmann valve gear. This set is direct-coupled, as are all the machines (except the two gas-driven ones) which generate current for the exhibition light and power supply; the main dimensions of the engine are 365mm. and 600mm. cylinder diameters and 750mm. stroke, and the armature is 2 metres in diameter, and weighs 4 tons.

Finally, I may mention a combination which appears somewhat incongruous to British eyes—viz., an 8-pole Thomson-Houston dynamo driven by a large single-cylinder Corliss engine. The dynamo has been made in France by the firm of Postel-Vinay for the French Thomson-Houston Co., and has a very workmanlike appearance. It has evidently been prepared in accordance with the American model, and differs from the American machine in a few details only. In type it is a tramway generator with a capacity of 325kw. at 550 volts and 90 revs. per min. The engine that drives it has been built by MM. E. Garnier & Faure Beaulieu.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

The Platinum Gas Thermometer.—For work at high temperatures the air thermometer with a platinum-iridium vessel is superior to a porcelain thermometer owing to the absence of softening, and the permeation of the gas, which in the case of hydrogen is troublesome, is obviated by substituting nitrogen for air or hydrogen. In continuation of their previous work on the subject, the authors have determined the correction to be applied on account of the expansion of the vessel. This expansion, which demands a correction of 10deg., 30deg. and 40deg. respectively at 500deg., 1,000deg. and 1,150deg., is not regular, and a further error of 1·5deg. to 7deg. is occasioned by the irregularity. The curve of expansion was determined by measuring the expansion of a rod made of the standard alloy, containing 80 per cent. of platinum and 20 per cent. of iridium. With a nitrogen thermometer subjected to the new corrections a number of melting points of metals were determined, so as to render future tests, especially those of thermo-elements, independent of the nitrogen thermometer. Thus the melting point of lead was found to be 326·9deg., of pure silver 961·5deg., and of gold 1,064·0deg. The last value was verified by an optical method, the refractive index of air exposed to the temperature of the melting point being measured. This also gave 1,064deg.

Magnetic Intensity Variometers.—The magnetism of a bar and the directive force of a bifilar suspension are not free from changes in the course of time, and are greatly affected by temperature. M. Eschenhagen has therefore adopted quartz fibres in order to obtain a simple torsional suspension. The systems of magnets and suspensions usually employed with magnetometers weigh at least 20 grammes to 30 grammes, and are therefore not suited for quartz fibres, as the latter would have to be too thick for the proper sensitiveness. The author has therefore provided a light system of magnets weighing about 1·5 grammes, and has found them to possess several distinct advantages, such as easy accessibility, adjustable damping, and a fixed mirror for photographic registration, which can be displaced with ease and certainty. For intensity variometers a quartz fibre, not too thin, about $\frac{1}{10}$mm. to $\frac{1}{20}$mm. thick, is selected, and the upper end is twisted until the magnet lies perpendicularly to the magnetic meridian. The author employs a simple expedient for increasing the sensitiveness of an instrument. He uses a fixed directive magnet parallel to the needle and below it. If the poles of the directive magnet are placed opposite the like poles of the needle the instrument becomes more sensitive, if in the contrary position it becomes less sensitive.

[M. Eschenagen, *Terr. Magnetism*, June, 1900.]

Cause of Terrestrial Magnetism.—An interesting attempt to reduce the phenomena of terrestrial magnetism to electric convection currents has been made by W. Sutherland. He supposes that the primary magnetic field of the earth is produced by a surface charge of negative electricity, which revolves with the earth, and whose motion through the ether produces the magnetic field. Astronomically, however, the earth does not act as a negatively-charged body, as its surface charge is compensated by an equal positive charge at the centre. The author shows that the surface density required would be 51,000 electrostatic units. The magnetic field outside the earth would be the only external evidence of the existence of the electrostatic field within. Secular variation is accounted for by a dissymmetry of the conductivity of the earth's crust, which induces a transverse field, and produces a potential similar to that of Barons's hypothetical transverse magnet. As regards the daily variation, the author points out that the process of dissociation induced by the sun in the upper strata of the atmosphere would produce a downward current of positive ions, and this would be the earth-air current to which the diurnal and other short-period variations have already been attributed. The currents are closed by flowing along the surface of the earth from equator to pole, by the glow discharge of the aurora in polar regions, and in the upper atmosphere by flowing from the pole to the equator.

[W. Sutherland, *Terr. Magnetism*, June, 1900.]

Dielectric Strain.—The expansion of a dielectric in an electrostatic field has been adduced as an experimental proof of the theories of Faraday and Maxwell, but the results described are anything but concordant. Röntgen ascribes the observed changes of volume to the electric compression of the electrodes and the heating effect of the free charges on the surface of the glass or liquid. L. T. More has endeavoured to meet this criticism by a special arrangement of three concentric tubes, the inner one being brass, enclosed in a glass tube surrounded by another brass tube. The results of his experiments, however, lead him to the conclusion that the stress occuring in the ether when a dielectric is electrostatically charged causes a mechanical deformation of the substance. At least, if there is such an action it must be extremely minute—perhaps a slight re-arrangement of the molecular structure—as an effect so large as one expressed by the formula $KH^2/8\pi$ would be very appreciable. Though it might have been expected that such ethereal stresses would change the length of a dielectric both along and at right angles to the lines of induction, yet as one of these is a tension and the other a compression of equal amount, it is difficult to see how any change of volume other than a differential effect would result; whereas Quincke finds that the change of volume is nearly three times as large as the linear expansion. A strain as indicated is not met with in any allied field of investigation.

[L. T. More, *Phil. Mag.*, August, 1900.]

IMPROVEMENTS IN THE CONSTRUCTION OF BATTERY MOTOR CARS.

In an article contributed to No. 11 of the *Centralblatt für Accumulatoren und Elementenkunde* Herr Zechlin states that there are two principles in the construction of motor carriages which he has already advocated—namely, that the weight of the vehicles should be reduced as much as possible, and that frictional resistance should be minimised by the employment of ball bearings. Diminishing the weight of the car reduces its traction resistance and lessens the shocks caused by the inequalities in the road; but there is a limit beyond which the weight cannot be reduced, even if the requisite mechanical strength could be obtained, and this is fixed by the weight necessary to give the adhesion requisite for continuous motion. This adhesion depends both on the weight of the vehicle and on the nature of the surface of contact between the wheel and the road, and if it is unduly reduced the ascent of an incline becomes difficult, and the steering is irregular whichever axle the driving impulse is applied to. The reduction of the weight of the vehicle is of special importance in the case of battery cars, and it should be the object of the designer of such vehicles that the total weight of the battery and car should not exceed the weight requisite to give the necessary adhesion. Most of the recent cars exhibit a marked improvement in the direction of weight, and thus also in reducing traction resistance and effecting a saving of energy. But from the result of the last few years' experience it does not appear that the weight either of the motor or of the batteries can be further materially reduced, so that it is only by improvement in the design and construction of the vehicles themselves that greater economy in working can be expected. If the weight is evenly distributed between the four wheels, it is more economical to allow the greater proportion of this weight to the battery rather than to the vehicles, provided always, of course, that due regard is paid to the strength of the latter. Allowing a larger proportion of the weight to be utilised in the construction of the battery permits of the employment of cells of the Planté type, which yield two or three times more discharges than do the lighter pasted plates.

Another method by which the economy of battery cars may be increased is by enlarging the diameter of the wheels. This method was first employed by Dr. Luxenberg at the Eisenach carriage factory. Small wheels are generally employed in benzine motors, because they are advantageous in going up and down inclines when the driving power is limited as it is in their case. The number of the revolutions, however, of the electric motor can be varied without sacrificing economy, and it can be overloaded, and therefore larger wheels can be employed with it, and the advantage which they confer in diminishing resistance be secured. The advantage of large wheels lies in the diminution of traction resistance which, according to Morin, is in the inverse ratio of the square root of the wheel diameter. For instance, if a wheel of 61cm. diameter is replaced by a larger wheel of 100cm., the traction resistance decreases in the proportion of one-eighth to one-tenth. A larger wheel also turns less frequently on its axle in a given distance, and friction and wear and tear are correspondingly diminished. The foregoing considerations point to the advisability of abandoning the old small-wheeled motor, which was based on the benzine type, and of substituting for it another especially designed to suit the conditions of electric motive power.

The value of ball bearings in reducing friction is recognised, but it is not equally well known that by paying due attention to the proportioning of their parts they may be made equally as economical as a well-finished ordinary bearing. The diameter of the balls should preferably be chosen so large that not more than 12 or 16 of them are required to form the ring; and for further details Herr Zechlin refers his readers to his articles on the subject in the journal *Der Motorwagen* for 1899. He also discusses the best form of tyre for electromobiles, and is in favour of a pneumatic tyre inflated to a pressure of 6 atmospheres.

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.
Editorial Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"The Electrician" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

New Volumes of "The Electrician" *commence in April and October.*

"The Electrician" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints" on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By E. Tremlett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d., post free 13s. Vol. II. Price 12s. 6d.; post free, 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. Vol. I.—The Induction of Electric Currents. New Edition. Price 12s. 6d., post free. Vol. II:—The Utilisation of Induced Currents. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. New Edition. 93 original illustrations, price 6s.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. New edition. Price 10s. 6d., post free; abroad 11s.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d.; post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free 2s. 2d. each; strong cloth 2s. 6d., post free 2s. 9d. each. Single Primers 2d., post free 2½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O. J. Lodge. New Edition. Price 5s. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, ELECTRIC TRACTION, TELEGRAPHS, TELEPHONES, &c. A. C. Curtis-Hayward, B.A. To January, 1900. Price 3s. 6d., post free.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work is in the press, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. Raphael. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

THE TELEPHONE.—By Dane Sinclair and F. C. Raphael.

SPECIAL NOTICES.

NOW READY.—Vol. XLIV. of "The Electrician" (960 pages) bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of "The Electrician" (1878-1900) can now be supplied. These sets are very scarce, and early application should be made.

NOW READY.—"THE ELECTRICIAN" READING CASE. Holds four copies of the Journal. Strongly made and corded for hanging. Price 1s.; post free, 1s. 4d.

THE EDUCATION OF AN ELECTRICAL ENGINEER.

Much has been written about the education of youths for an electrical engineering career, and from platform and printed page there has been frequently given to the world a multiplicity of advice on the subject. We ourselves are often asked to point out the course of education and training which a youth should go through in order to become a qualified electrical engineer. It is, however, impossible, either in writing or verbally, to lay down any rigid rules, or to recommend any fixed scheme; for it is essential that each case should be considered on its own individual basis, and what may safely be advised in one case will differ in many essential details from what should be followed in another. This being so, it might appear superfluous to discuss the subject further on the present occasion. Much has already been put into print, and the utmost that could be printed could never settle the matter: why, then, spill more ink? Nevertheless, there are a few general considerations which may usefully be placed before anxious parents and guardians, many of whom are quite out of touch with even the outermost of electrical circles. And the present season being the one when this problem most generally presses for solution, it may be appropriate for us to make a few remarks upon it now, both as offering suggestions to electrical engineers who are being consulted on the matter, and as giving direct advice to the interested parties themselves.

We have said that each case must be considered in its individual circumstances. Those who have had to do most with technical education will appreciate most the force of this remark. The aspirants, to begin with, are of diverse ages, some being mere boys, others men who have abandoned a different career of some years standing; some possess abundant means for a full course of study, others require to enter the doors of the profession with a minimum expenditure of time and money. Then again—and this is noticeable even among the boys—some bring with them a grounding in mathematics and the physical sciences, while others have nothing but classical lore and must not only be taught the elements of mathematics and physics but also require the laborious drilling in thought which is necessary before they can even

Digitized by Google

get into a mathematically exact way of thinking. We do not wish here to raise the question as to the merits of classical education; all we are contending now is that of two youths of equal ages, fresh from school, that one will be better prepared to commence a course of study for an electrical profession who brings with him a foundation of elementary mathematics and physics, than will be the one in whose mind these subjects are replaced by Latin and Greek. In other words, the classical scholar will require to add an extra year or two to the term of his technical studies, in order to make up the deficiency. He will enter the profession at a later age, but we do not contend that he will not be the better man in the end.

It is a matter for surprise to us that so much difference of opinion exists in the electrical profession as to whether a youth should take first his studies at a technical college and then the more practical training of the workshops or power station, or should reverse the order of these two things. To us it appears that the former is by far the better course to adopt. We are aware that the opponents of this plan contend that it allows the pupil to go through his classrooms and laboratories without knowledge of the practical work for which he is fitting himself. In these days, however, of students' "visits to works" a youth has abundant opportunity to learn enough of the practical side to perceive the drift of his studies. Moreover, there is an immense advantage in entering the "works" stage of his studies with a thorough knowledge of the theoretical and scientific bearing of what goes on in workshops. Besides all this it is a more natural transition to pass from the school-room to the lecture-room and laboratory, and from the works to whatever may be the practical occupation with which his career is commenced, than to transpose this order of things.

According to the qualifications with which he commences, the first year or two of a student's college course should be practically independent of the special branch of the electrical profession he will ultimately enter. Up to this stage the majority of aspirants, and their parents or guardians with them, display the liveliest ignorance of what that special branch is to be. There is great anxiety for the young man to enter the profession, but not the faintest idea exists as to whether he is to be an electric light engineer, or an electro-chemist, or a telephone engineer, or a telegraphic engineer, or a tramway engineer. Even if it were possible to predetermine the special branch at the earliest stage, it would probably not be advisable to modify the early studies very much though possibly an electro-chemical career would call for greater attention to chemistry and less to mechanics than would, say, electric traction. On the whole, however, the broad foundation should be the same for all branches, and it should be made as broad as possible. Even to an electro-chemist a liberal knowledge of mechanics will be useful, and the tramway engineer will not regret an acquaintance with electro-chemistry however much he may deplore the evidence of it in the electrolysis on his lines. The later years of study at a technical college are of course determined wholly by the nature of the chosen branch of the profession, and little need be said here on this part of the subject. We would, however, warn students against a too early and too exclusive absorption into what is termed research work. Professors are sometimes far too prone to use their best pupils as handy assistants in working out some one line of research in which the teachers happen to be interested. Students attend technical colleges to lay a sound and broad foundation for their life's work, not to aid professors in preparing Papers for scientific societies.

When the college course is ended, the student should regard it as almost, if not quite, essential that he should pass completely through the workshops of an electrical or mechanical engineering works; and only a firm of high standing, doing a variety of work of an electrical or kindred character, should be selected. As this stage must occupy several years, it is sometimes curtailed or, unfortunately, omitted altogether. No student, however, can regard his training as complete unless he has acquired a practical insight into workshop methods; but we are glad to observe that the notion is now gradually dying out, that no one is an engineer who has not been duly articled and passed through engineering works. When it is impossible to devote any time to the workshop, a student will sometimes commence his practical training by being articled as the pupil of a central station engineer. For a youth intending to become a station engineer this is an excellent introduction, even after two or three years have been devoted to workshops. But that a thorough training in engineering works renders this unessential is proved by the strikingly successful example of the Corporation electrical engineer at Glasgow. That gentleman, it will be remembered, went to this important and responsible post straight from the works of Messrs. Crompton & Co. at Chelmsford. In conclusion, we may point out that the old days of rule-of-thumb engineering are gone, never to return, and that the education of an electrical engineer to-day consists in a solid foundation of scientific facts and principles, with a substantial superstructure of intelligent practice.

THE USE OF ALUMINIUM FOR ELECTRICAL CONDUCTORS.

BY JOHN B. C. KERSHAW, F.I.C.

Introduction.—The issue of *The Electrician* for Sept. 8, 1899, contained an editorial note dealing with the offer of a continental firm of manufacturers to supply aluminium wire for electrical purposes at 1s. 2½d. per pound. In America the Pittsburg Reduction Co. have been vigorously pushing the use of the new metal for electrical transmission lines since 1897, and have supplied large quantities of aluminium for this purpose at the low price of 1s. 2½d. per pound. As a result of these offers, and as a result also of the high price of copper, G.M.B.s of which have now for 18 months remained over £70 per ton, numerous trials of aluminium for electrical work have been made in Europe and America. On this side of the Atlantic these trials have been experimental and tentative in form, and one can point to no *large* installation of electricity, either for power or lighting purposes, in which aluminium has supplanted copper. In the United States, however, the trials have been carried out on a very large scale, and transmission lines of aluminium varying from 20 to 40 miles in length, carrying 1,000 H.P. to 5,000 H.P., at 10,000 to 20,000 volts pressure, have been erected at several places on the Pacific Coast. Time alone will show which is the wiser policy. It is not yet possible to state definitely whether aluminium possesses all the qualities necessary to make it a successful rival of copper; and if these aluminium transmission lines should ultimately require to be replaced by the older metal, the losses incurred will be exceptionally heavy. The importance of the subject, therefore, justifies a special article dealing with it alone, and in the following notes the writer has gathered together all recently-published facts and figures relating to the use of the new metal as an electrical conductor, supplementing them in some cases by his own figures.

Relative Conductivity of Copper and Aluminium.—The relative conductivity of 99·6 per cent. aluminium, taking copper 100, and equal sectional areas, is 61·5 according to Northrup,*

* *Electrical World* (New York), Dec. 3, 1898.

Digitized by Google

and 60·5 according to Lord Kelvin.* Since it is customary to alloy the aluminium designed for use in transmission lines with copper or iron in order to increase its strength, it is obviously unfair to use these figures in general calculations regarding relative costs, yet this mistake is constantly being made by those interested in the subject. Thus C. T. Child in a recent article has based all his calculations upon a conductivity ratio of 63 : 100† ; and another writer has used the ratio 61 : 97 in similar calculations.‡ Northrup has shown that the conductivity of aluminium falls rapidly with increasing percentages of copper, and the following are figures obtained by him with special brands of aluminium manufactured by the Pittsburg Reduction Co. for conducting purposes :—

Aluminium alloyed with 0·50 per cent. copper	58·16
Do. do. 0·75 do. do.	56·37

It is evident, therefore, that calculations based upon a ratio of 63 : 100 will yield erroneous results for all cases in which copper or iron has been added to the aluminium in order to increase its strength ; and only in such cases as that of the Niagara Falls Power Co.'s aluminium transmission line, running from the power-house to No. 2 works of the Pittsburg Reduction Co., is a relative conductivity of over 60·5 : 100 attained. In this case the line is short, and, as little tensile strength was required, the writer believes that the metal was not alloyed with copper.

In the Blue Lakes and Stockton transmission line, one of the latest installations of aluminium for long-distance transmission, the wire used had a conductivity of 59·9 as compared with copper at 100, but the total resistance of the line was 10 per cent higher than calculated, owing to impure metal in certain sections of the line.§ Taking the former figures, it would appear from Northrup's tests that the aluminium was 99·6 metal, alloyed with about 0·30 per cent. copper.

The writer has had tests made of aluminium wire supplied to him for experimental purposes by firms in this country, with the following results :—

		Aluminium.		Copper.
No. 1 }	Conductivity of equal sectional areas	51	:	100
No. 2 }		54	:	100

These figures show that each lot of aluminium wire or cable ought to be tested separately for conductivity before erection on any power transmission line, and that the percentage of copper and iron added to the metal ought to be kept as low as is consistent with the desired strength of the line.

Relative Strengths of Copper and Aluminium.—The tensile strength of hard-drawn copper wire is between 62,000lbs. and 65,000lbs. per square inch. The tensile strength of aluminium wire is much lower, and varies from 18,000lbs. to 40,000lbs., according to the impurities present, and the annealing it has undergone. The tensile strength of aluminium and copper alloys varies greatly, since as pointed out above, a slight variation in the percentage of copper present has a marked effect upon the physical properties of the metal. In the majority of instances no special analysis of the alloy is made at the time of carrying out the physical tests, and the percentage of copper present is a matter of pure conjecture. Thus the tensile strength of 99 per cent. aluminium is stated by one authority to be from 80,000lbs. to 55,000lbs. per square inch when drawn into wire, but no reference is made to the amount of copper present. The wire used for the Blue Lakes and Stockton (California) transmission line possessed a tensile strength of only 82,700lbs. per square inch, and as the conductivity was 59·9 we may assume it contained 0·30 per cent. copper.§ Prof. Carpenter, of Cornell University, has published tests which give 15,000lbs. per square inch, as the maximum tensile strength for 99 per cent. aluminium ; but the metal used no doubt contained other impurities in place of copper,‖ and it was not in the form of wire. Drawing into wire always increases the strength of metals, and aluminium is no exception to the rule ; but several annealing operations are necessary in the course of this drawing-down operation.

The writer has obtained the following figures for aluminium wire supplied to him by firms in this country :—

No. 1. 99 per cent. aluminium	32,490lbs.	per square inch.
No. 2. Alloy containing 1 p.c. iron ...	38,080lbs.	do.
No. 3. Composition not stated	31,600lbs.	do.

The breaking strains fixed by the authorities for overhead electric wires in different countries are as follows :—

United Kingdom..	31,360lbs.	per square inch.
United States	32,000lbs.	do.
France	31,218lbs.	do.

Aluminium used for overhead lines must therefore be alloyed with sufficient copper or iron to give it a tensile strength of over 32,000lbs. per square inch, and, as stated above, on the Stockton line this has been attained with a percentage of copper not exceeding 0·30 per cent.

As evidence of the great increase in strength which is conferred by increase of the percentage of copper, it may be stated that the Pittsburg Reduction Co. have produced a wire the breaking strain of which is 65,000lbs. per square inch, or equal to that of hard-drawn copper. The conductivity of this wire is, however, only 50 per cent. of that of electrolytic copper, and for long distance transmission work, it is therefore of little value.

Relative Costs of Copper and Aluminium.—It has been stated above that aluminium has been offered and sold in rod or wire form in America, for electrical transmission work, at 1s. 2½d. per pound, and in Europe at only a slightly higher cost. Whether there is much, or any, profit for the producer on these transactions, it is not at the moment the writer's intention to inquire. Taking the latest quotation for copper in rod form, namely, £84 per ton, equal to 9d. per pound, and using the figures for relative conductivity given above, namely, 59·9 : 100, the relative costs of aluminium and copper for conductors of equal electrical capacity work out to

$$\frac{2{\cdot}68 \times 14{\cdot}5 \times 100}{8{\cdot}93 \times 9{\cdot}0 \times 59{\cdot}9} = \frac{3{,}886}{4{,}814} = \frac{100}{123}.$$

As an example of the error occasioned by the use of a wrong figure for the conductivity in such calculations, the above has been re-worked with C. T. Child's figures of 63 in place of 59·9. The cost ratio then comes out as $\frac{100}{130}$, a difference quite large enough to severely diminish the expected savings on a large scheme. Taking the figures first obtained as the more correct, we see that at the present high price of copper, aluminium is considerably the cheaper metal for electrical work, and that for equal carrying capacity £100 expended on aluminium will balance an expenditure of £123 on copper. It must be remembered, however, that these figures represent the relative costs of the metals *only*, and that costs of erection, &c., may help to equalise the total outlay as between the two metals.

Erecting and Jointing Aluminium Transmission Lines.—The jointing of aluminium has long been a difficulty in connection with the use of this metal for electrical work, and many methods of overcoming it have been tried. The difficulties are caused by the skin of oxide which covers aluminium surfaces, and by the tendency of all aluminium alloys to disintegrate on exposure to damp air. Hence a good soldered joint is difficult to make ; and when made, it is exceedingly liable to become rotten after a few months' exposure. In the States, where most experience in this direction has been gained, a mechanical joint has been adopted for small wires that can be bent and twisted without injury, and solder is only used for the larger and thicker wires and for bars. The usual form of mechanical joint consists of a thin aluminium tube through which the two ends of the wire are drawn in contrary directions. The tube is then crushed in on the wires, and the two free ends of the latter are bent back and twisted round the tube. A full description of this method of jointing will be found in the Paper named below.* It was the method

used on the original Blue Lakes and Stockton power line, and it is to be adopted for the line which is now being erected in place of the earlier one.

With regard to the precautions to be observed in erecting aluminium transmission lines, Messrs. Perrine and Baum give very full details in a Paper which they have recently read before the American Institute of Electrical Engineers, and as many of the points upon which they touch are of the highest importance the writer has thought it well to reprint some of their remarks in full below :—*

In carefully performing the test for tensile strength no exact point could be assigned for the elastic limit, as the metal seemed to take a permanent set almost from the first, but at a stress of from 14,500lb. to 17,000lb per square inch, there is a marked increase in the permanent set which indicates that the safe working load lies somewhere in this region. In this the characteristics of the aluminium do not differ materially from those of copper or other similar metals, and while this is a disadvantage it is not a singularity.

The fact that the wire will permanently elongate if seriously strained makes it necessary to use the utmost care in the erection of lines, and also the known high coefficient of expansion with temperature changes, taken in conjunction with this property, renders care in line stringing especially important and difficult.

Instructions to Line Foremen in Stringing Wires.

1. All spans are to be strung with deflections and tensions as specified.
2. Up-and-down hill spans to be sprung to correspond with level spans. In case level spans cannot be used, then employ dynamometer, and ease all wires over cross-arms.
3. All ties are to be made at one time by signal.
4. All ties are to be made crossing wires around insulator, serving three times around wire, and twisting behind insulators ; the ends of the tie wires are not to be cut but bent back toward insulators.
5. Tie all wires on the outside of the insulators, except at corners, where all are to be tied so that the strain is against the insulator.
6. Joints are to be made by means of sleeves twisted two and a-half times, the ends of the wires being given one turn by hand around the wire, no tools being used except in twisting the sleeves and cutting off the ends of the wires. Before inserting the wire in the sleeve the ends of the wire must be roughened by draw filing.
7. Barb wire is to be laid along the roof of the pole and held by three staples driven in tightly, but without kinking the wire. Ground wires are to be soldered to the barb wire, and at the bottom of the pole to the wire leading from the ground plate. All soldering acids must be carefully washed away after the soldering is done.
8. Beginning between poles 1 and 2, all wires are to be barrelled by shifting one pin, and same to be repeated between poles 21 and 22, and 41 and 42, and so on, barrelling always in the same direction of twist every 20 poles. A record must be kept of the location of every wire and every pole.

General Caution.

The greatest care must at all times be taken against kinking or scarring the wire ; wherever the wire is accidentally kinked or scarred it must be cut and spliced.

These directions would seem to indicate that the erection of aluminium lines is more troublesome than when copper is the metal used, and that therefore the cost of erection will be somewhat higher in the case of the lighter metal. Exact figures bearing upon this point, however, are lacking.

(*To be continued.*)

A Loud-Speaking Phonograph.—Mr. H. L. Short, of Brighton, has invented a loud-speaking phonograph, which in appearance is merely an ordinary phonograph, with a large trumpet, measuring 4ft. in length. Inside this trumpet there is a small and delicate piece of mechanism that looks something like a whistle. This is the tongue of the machine. Instead of the "records" being taken on wax in the usual manner, a sapphire needle is made to cut the dots representing the sound vibrations on a silver cylinder, and when the needle travels over the metal a second time the vibrations cause the whistle to produce a series of air waves and the machine thus becomes a talking siren, which transforms the human voice into a deafening roar. Experiments have been made near the Devil's Dyke, Brighton, where the inventor has his workshops. The instrument was placed on the roof of the laboratory and was made to repeat a number of sentences. At a distance of 10 miles, it is said, the sounds were plainly heard by a large number of people, every word being perfectly distinct; and at a second trial, with favourable wind, it was found that an unknown message could be taken down in shorthand at a distance of 12 miles.

BRITISH ASSOCIATION.

We give below a provisional list of the Papers to be read in Section G. (Mechanical Science) at the meeting of the British Association at Bradford :—

Thursday, September 6th.

Sir ALEXANDER BINNIE.—Presidential Address (11:30 a.m.).
JAMES WATSON.—"Bradford Waterworks" (2 p.m.).
JOHN MCTAGGART.—"The Disposal of House Refuse in Bradford."

Friday, September 7th.

Prof. HELE SHAW, F.R.S.—"Resistance of Road Vehicles to Traction."
W. H. H. DAWSON.—"Recent Tramway Construction, with special reference to the Demerbe system."
J. H. GLASS.—"The Coal and Iron Ore Fields of Shansi and Honan, and Railway Construction in China."
A. T. WALMISLEY.—"The Use of Expanded Metal in Concrete."
J. B. C. KERSHAW.—"Power Generation—Comparative Cost by the Steam Engine, Water Turbine, and Gas Engine."

Saturday, September 8th.

Prof. R. BEAUMONT.—"The Application of Photography to Textile Designing."

Monday, September 10th.

W. A. PRICE.—"Report of the Small Screw Gauge Committee."
A. MALLOCK.—"Measurement of the Tractive Force, Resistance, and Acceleration of Trains."
Sir W. H. PREECE, F.R.S.—"The Liverpool and Manchester Electric Railway."
A. H. GIBBINGS.—"The Design and Location of Electric Generating Stations."
T. BARKER.—"A Maximum Demand Meter."
J. W. BINNIE.—"An Account of a New Form of Self-registering Rain Gauge."
J. G. W. ALDRIDGE.—"The Automobile for Electric Street Traction."

Tuesday, Sept. 11th.

Prof. J. GOODMAN.—"A New Form of Calorimeter for Measuring the Wetness of Steam."
Prof. ARNOLD.—"The Internal Architecture of Steel."
E. E. CLARK.—"Shop Buildings."
H. R. ARMITAGE.—"Steam Raising and Smokeless Combustion."

ELECTRICITY WORKS ACCOUNTS.

Bristol Municipal Electric Supply Works.

The Bristol accounts for the year ended at March 25 last, which we analyse this week, exhibit figures indicating excellent results. The most striking feature is the reduced fuel cost per unit sold. It must be admitted that the fuel item for 1898-9 was materially above the average under similar conditions of output and load-factor. Still, to have effected a reduction in this charge in the face of the stiff coal prices which have ruled, especially in the West of England lately, is a matter upon which the engineer at Bristol is to be highly congratulated.

The generating costs in general show a decided diminution, but the management charges have increased, largely in consequence, we learn, of sundry items being charged to revenue that have not hitherto been so charged. Thus, the departments, engineers have been carrying out all new work themselves, and the salaries of certain members of the staff engaged almost exclusively on capital work are being charged against revenue account.

To a considerable extent the favourable generating and works costs attained during the year must be attributed to the improved output and load. The number of units sold in 1899-1900 mark an advance of 33 per cent. on the number of 1898-9, while the load-factor has made the sp'endid increase from 9·12 per cent. to 12·35 per cent. The lamp connections indicate an increase of nearly 24 per cent.

In the table on the next page some additional and interesting particulars are given relative to the undertaking.

Portsmouth Municipal Electric Supply Works.

Although a regrettable increase in the costs is noticeable in the accounts of this undertaking, the items which have risen are only three, of which, as was to have been expected, fuel was one. The increase of 0·22d. in this item represents by far the greatest proportion of the increase in the works and total cost items.

* 3 months. † Approximately.

We are glad to note that in spite of the advance in the aggregate costs, they are still well below the average 1898 costs in municipal stations of similar output and load-factor. This is saying a good deal when the greater cost of coal is taken into account.

The other items which have risen are those of distribution costs and management charges. The former have been added to by the expenditure on removable transformer switches and alterations to transformer pits to accommodate these switches.

Owing to a decrease in the rents, rates and taxes the collective management and property charges have fallen very slightly from the already low figure of 0·38d. per unit. in 1898-9.

The output has made but slight progress, the increase being only 13·7 per cent., and unfortunately there has occurred a falling off in the value of the load-factor from 12·35 per cent. to 12·06 per cent. In these circumstances the figures exhibited in the costs column are certainly most creditable, and it is unfortunate that the general position of the undertaking has been marred by the small advance in the business done.

THE MAGNETIC FORCE OF THE ATOMS.*

BY ROBERT LANG.

Ampère's hypothesis of molecular currents has in recent times acquired a more concrete form owing to the currents generating the magnetic field being regarded as convection currents of revolving ionic charges. F. Richarz† has more especially dealt with this question, and in his work we also find references to the previous work of W. Weber, Ebert, and Chattock. Since that work I have not met any which deals with the question in greater detail. Richarz has limited himself to examining the admissibility of the explanation of molecular magnetism by the rotation of valency charges, calculating the magnetic moment of saturation for iron direct, and finding it to agree as regards order of magnitude closely with the experimental value.

In what follows I intend to show (1) that this proof can also be brought while using values differing essentially from those employed by Richarz; (2) that thus we possibly obtain a connection between minimum atomic volume and magnetism which up to the present has also been empirically recognised; (3) that with regard to atomic magnetism the unsaturated valencies appear to play an important part; and (4) that the new hypothesis permits the consistent explanation of several phenomena hitherto imperfectly understood.

I.

From the consideration that revolving valency charges emit electrodynamic waves, and that their period must be longer than that of the extreme visible red light, and from a contemplation of the kinetic energy of this motion, Richarz finds for the period of revolution T the limits

$$3\times10^{-15} < T < 10^{-12} \text{ secs.}$$

and eventually puts as an approximation $T \backsim 10^{-14}$ sec. He further calculates the diameter of the orbit of an ion, and puts it equal to the edge of the elementary cube of the iron atom, $1·5\times10^{-8}$ cm. With the value 43×10^{-22} C.G.S. for the valency charge we have, therefore, by the theorem of equivalence between a circular current and a magnet, the magnetic moment of an iron atom as 2×10^{-22} C.G.S. units, and therefore, since the number of molecules in 1 gramme of iron is estimated at 4×10^{21}, the saturation moment of iron comes out as 8 C.G.S. units. Experiment gives 220 and 150 for cobalt and 60 for nickel. Richarz, therefore, considers the attempt to reduce the molecular magnetism existing before the orientation of the elementary magnets to a rotation of the ionic charges as admissible.

Now, very little is yet known concerning the inner structure of metals, whereas, on the other hand, our conceptions with regard to solutions of electrolytes have in recent years been widely extended. It therefore appears expedient to test the value of the hypothesis mentioned, not by a metal, but by solutions of its salts, and all the more since experiments with dilute paramagnetic solutions are capable of great accuracy, and have, indeed, been largely performed and published. Among the older ones there are more especially those of G. Wiedemann, and, recently, those of G. Jäger, S. Meyer, J. Königsberger, H. du Bois, and O. Liebknecht—which should be mentioned. We employ for the test the interesting results of the first two modern physicists, Jäger and Meyer,* obtained for solutions of chlorides, sulphates, and nitrates of the four magnetic metals nickel, cobalt, iron, and manganese, which show (1) that only the metallic contents determine the magnetic susceptibility, (2) that the atomic susceptibilities of Ni, Co, Fe, and Mn multiplied by 10^6 are 4·95, 10·0, 12·5, and 15·0 C.G.S. units respectively, and therefore are in the ratio 2 : 4 : 5 : 6. Both these results are confirmations or extensions of theorems already found by G. Wiedemann. The figures refer to 17·5°C. and to fields of 1×10^4 to $1·8\times10^4$ units. Within this interval no dependence of the magnetic susceptibility upon the field strength was shown, so that it may be assumed that saturation was attained.

Let us therefore calculate in Richarz's manner the maximum magnetic moment of 1cc. normal $FeSO_4$ solution (1 gramme-molecule in 1 litre of water). According to Nernst, it contains $5·4\times10^{19}$ molecules, and therefore as many iron atoms. With Richarz's number 2×10^{-22} for the magnetic moment of the iron atom we obtain for the saturation moment of 1cc. of $FeSO_4$ solution $1·08\times10^{-2}$ C.G.S. units. According to G. Jäger and S. Meyer, this moment is $4\pi\times12·5\times10^{-6}\times10^4 = 1·57$ C.G.S. units. Hence we may say that the accordance is about the same as in metallic iron; the calculated moment is 27 or 145 times smaller than the real moment.

If, therefore, we consider Richarz's explanation of molecular currents through central motions of the ionic charges as possible in principle, we must not forget that this reasoning requires certain arbitrary assumptions. In the first place, it is assumed that $T > 3\times10^{-15}$ secs., *i.e.*, that the rotations take place more slowly than the vibrations of the extreme red light, since otherwise they would be perceived as light.† But there is evidently another possibility, viz., that $T < 7\times10^{-16}$ sec., or that the rotations occur more rapidly than the vibrations of the extreme violet light. Again, Richarz puts the diameter of the orbit of the revolving ions equal to the edge of the elementary cube of the iron atom, for which he finds the value 10^{-8} cm. We see that this is also the average value which the kinetic theory of gases assigns to the size of molecules. Considering that the atoms only partially fill up their space, and considering the special circumstances, that it is just the magnetic substances which are distinguished by a minimum atomic volume, it appears very probable that the diameter of the ionic orbit is less than 10^{-8} cm. To investigate this possibility put $T \backsim 10^{-x}$ sec. and the diameter of the orbit $\backsim 10^{-y}$ cm. Then the magnetic moment of the di-valent Fe atom is

$$(2\times43\times10^{-22}/10^{-x})\times10^{-2y} = 8·6\times10^{-21+x-2y} \text{ C.G.S.}$$

Hence the moment of 1cc of normal $FeSO_4$ solution

$$= 5·4\times10^{19}\times8·6\times10^{-21+x-2y} = 4·6\times10^{-1+x-2y} \text{ C.G.S. units.}$$

Putting this equal to the experimental value 1·57 C.G.S., we obtain from a comparison of the orders of magnitude.

$$x = 2y + 1.$$

Hence for

$$y = 9 \text{ we have } x = 19,$$
$$y = 10 \quad " \quad x = 21, \text{ \&c.}$$

Here we have for the longest periodic time $T \backsim 1 \cdot 10^{-19}$ sec. We see, therefore, that these numbers fulfil the condition put down for T, and that even in the case of the largest value there is room for ultra-violet light.

For all correlated values of T and δ we have for the magnetic moment of a Fe atom considered as di-valent the value $8 \cdot 6 \times 10^{-20}$ C.G.S., and for the saturation moment of 1cc. of normal $FeSO_4$ solution 4·6 C.G.S., instead of 1·6 C.G.S. This shows that the explanation of the molecular currents by ionic revolutions is also possible on the basis of values which considerably differ from the order of those adopted by Richarz. Exactly the same value comes out for the magnetic saturation moment of 1cc. of normal solutions of $CoSO_4$, $NiSO_4$, $MnSO_4$, or the chlorides and nitrates of the four paramagnetic metals considered as di-valent. For in a physico-chemical sense, as far as is known, all these solutions are in the same condition. They are, for instance, probably dissociated to the same extent, and the atomic weight and atomic volume for all the four metals considered is nearly exactly the same. But if actually the atomic magnetisms are different, and stand in the integral proportion of 2 : 4 : 5 : 6, it is obvious to assume that this behaviour is connected with the various free valencies of the metals. For it appears probable beforehand that not all the valencies of the atoms but only the free ones are in rotation, and that therefore *only the latter* are responsible for the generation of atomic magnetism. Hence the free valencies of Co, Ni, Fe, and Mn in the solutions in question should be as 2 : 4 : 5 : 6. If there is any truth in this, chemistry acquires in the magnetic examination of paramagnetic solutions an instrument which permits an attack at all events upon a range of investigations hitherto as good as entirely closed.

According to Mendelejeff, the following salt-forming oxides of our four metal occur :—

Ni_2O_2, Ni_2O_3

Co_2O_2, Co_2O_3, Co_2O_4

Fe_2O_2, Fe_2O_3, Fe_2O_4, Fe_2O_6

Mn_2O_2, Mn_2O_3, Mn_2O_4, Mn_2O_6, Mn_2O_7.

The oxides of the form R_2O_2 correspond to the salts of our magnetically-examined solutions. The rest give, by the possibility of their existence at least an indication of the number of their free valencies. Excluding multiple combination, we have for the proportion of the free valencies the numbers 2 : 4 : 8 : 10. It is quite possible that with multiple linking, especially of the more complicated combinations Fe_2O_6 and Mn_2O_7, the proportion becomes 2 : 4 : 5 : 6.

Clearly, the salt solutions of the magnetic metals represent a simpler case than the metals themselves, just as from a dielectric point of view gases are simpler than liquids. Here it is interesting to note how as regards magnetic susceptibility the free valencies appear to have the determining influence, while for the dielectric capacity the total sum of valencies of the simple or compound molecules appears to be the determining element.

We return once more to the values of T and δ found above, and consider the maximum values $T \backsim 10^{-19}$ sec. and $\delta \backsim 10^{-9}$ cm. T appears at first surprisingly small, while the orbital diameter δ differs less from the usual value. But these numbers lose much of their extraordinary appearance by the following consideration. Richarz lets the valency charges rotate with the material atoms themselves, in order to obtain the lower limit for T. Hence he has to deal with the inertia of matter. But here we shall adopt the view put forward by J. J. Thomson, P. Drude and others, based upon experiences in cathode and canal rays. The chemical atoms consist of greater and smaller electrons with definite electric charges. For the smaller ones, the cathode ray particles, the ratio of charge to mass, has been determined by Kaufmann* to be $1 \cdot 26 \times 10^7$ C.G.S. The greater electrons, probably positive, have the same charge, but greater mass. Thus Drude† finds for Ni the ratio of masses for negative and positive electrons from optical data to be 1 : 9·45.

In the case of molecular currents we may, therefore, regard the greater electrons as nuclei, about which the smaller ones as satellites revolve, their period of revolution being $T = 10^{-19}$ secs. From this conception we derive a calculated linear velocity of the small electrons of $\pi\delta/T \backsim 10^{10}$ cm. per second, which is of the order of the velocity of light. That is also the velocity with which the electrons, as cathode particles, fly across the Crookes' vacuum by the concurrent evaluation of J. J. Thomson ($1 \cdot 5 \times 10^9$), P. Lenard (0·67 to $0 \cdot 81 \times 10^{10}$), and W. Wien ($10^{10}$ cm. per second). Hence we can hardly doubt that the electrons can indeed acquire such extraordinary velocities provided they are impelled by a suitable force. This force is, in the case of cathode rays, furnished by the high potential gradient at the cathode. It is another question whether the electrons possess such velocities in their natural condition, without assignable cause. In answering this question, Becquerel's latest measurements in connection with the rays described by him are very important. By magnetic deflection he found, for the particles emitted by radium preparations, the value $(m/\epsilon) \times v = 1{,}500$. For cathode rays the same product is 1,030 to 1,273. Now, the radium particles are pretty certainly not larger than the cathode ray particles, and thus the natural velocity of the particles emitted by the radium preparation is at least of the order of 10^{10} cm. per second. Hence we conclude that the equal velocity of the electrons obtained in the case of the central motions supposed to produce magnetism is, at all events, not impossible.

As regards the orbital diameter δ, whose greatest value we have found to be about 10^{-9} cm., we must at once admit that δ^3 does not strictly agree with the atomic volume indicated by chemistry as the ratio of atomic we get, and specific gravity in the solid or liquid states, and which turns out to be a minimum in paramagnetic bodies. Generally speaking, the atomic volume will be greater than δ^3. On the other hand, we may assert that the larger δ, and hence the larger the more or less circular orbit described by the electrons the greater will be the sphere of molecular action, and, inversely, a diminution of the atomic volume will be accompanied by a diminution of δ. Although, therefore, a direct and similar alteration of the atomic volume and the diameter δ cannot be strictly proved, yet such a connection is probable, and in any case we have here for the first time theoretically a necessary metrical relation affecting magnetism, which is closely related to the empirical rule of the minimum atomic volume of magnetic substances.*

II.

We have seen in the last part that the new interpretation given to molecular magnetism does not contain any contradictions and is therefore possible. We shall further show that it casts new light on some phenomena hitherto unexplained.

1. Two conditions attend, as we have seen, the presence of paramagnetism—minimum atomic volume and force, *i.e.*, unsatisfied valencies. Both conditions are fulfilled by oxygen. As regards atomic volume, Meyer's table may be consulted,† and as regards the tetravalence of oxygen, which is usually di-valent, that of Heyes.‡ Hence it is not surprising that oxygen is paramagnetic, while most other gases are diamagnetic. If we imagine, then, two links of each atom bound in the oxygen molecule, and the others free, we get as before for the magnetic moment of an oxygen atom $4 \cdot 6 \times 10^{-1+x-2y}$ C.G.S. R. Hennig, on the other hand, found for the susceptibility of oxygen in comparison with a vacuum at 25°C. and the atmosphere, the value $0 \cdot 12 \times 10^{-6}$ C.G.S, the field being about 10^4 units. This gives for the magnetic moment of 1cc. oxygen under the conditions indicated the value $4\pi \times 0 \cdot 12 \times 10^{-6} \times 10^4 = 1 \cdot 5 \times 10^{-2}$ C.G.S., from which, by comparison of the indices, we obtain $x - 2y = 1$.

Hence we have for $y = 9$, $x = 17$,

$y = 10$, $x = 19$, &c.

Since a period $T = 10^{-17}$ lies too close to the ultra-violet rays we should give preference to the second pair of values.

We see that the values are of the same order of magnitude as in the case of iron, except that the diameter δ of the orbit appears somewhat smaller. But we may remark that the value of the magnetic moment employed by Richarz for a tetravalent Fe atom—viz., 2×10^{-22}, also gives a correct result when we utilise the free valency idea, although it is doubtful whether the iron atom may be directly replaced by the oxygen atom in a magnetic point of view.

2. From his ample material concerning magnetic susceptibilities S. Meyer deduces the following empirical rules: The molecular magnetism k of the paramagnetic combinations is smaller than the sum of the atomic magnetisms of the constituents. Oxidation seems generally to depress the k of the element, so much so that paramagnetic metals may yield diamagnetic oxides.

The first rule is a direct and general consequence of our conception of the part played by unsatisfied valencies in the genesis of magnetism. For in the chemical combination of two bodies we have always to do with the joining of valencies. Hence the magnetic susceptibility of a combination of paramagnetic bodies can at the utmost only be the sum of the atomic susceptibilities, but will mostly be smaller. Should the case occur that all the valencies are bound, or that the rotation of the unsatisfied valencies is hindered by the binding of the others, the combination may be diamagnetic. The second rule of Meyer furnishes an example of this. That the combination of two diamagnetic bodies, in the case that one of them at least has a small atomic volume, should appear feebly paramagnetic, may be explained by supposing that by the combination of some valencies between the atoms other links hitherto bound become free. This case will, of course, be a rare exception, although possible. Perhaps the copper compounds furnish such an example.

3. The third application refers to the kernel of the new hypothesis—viz., the order of magnitude of the values in question. We imagine, as already explained, that greater nuclei, probably positive ones, are surrounded by smaller nuclei, probably negative, which revolve as satellites round them. It is not necessary to consider the negative electrons as permanently attached to their nuclei. It is, indeed, probable that the various electrons have different velocities in their central motions, and that the value indicated represents a mean value. Now, if an electron attains a much larger velocity than corresponds with its period of revolution, it can proceed from the sphere of influence of one nucleus into that of another. This, of course, alters nothing in the conception made of the stationary condition of a magnetic body.

Imagine an iron rod longitudinally magnetised to saturation, and let the magnetic lines of force within it run parallel to the axis, so that they only enter the air at the terminal surfaces. Then the planes of the orbits of all the electrons are all parallel to each other, and perpendicular to the axis of the rod. A cross-section of the rod contains all the orbits whose centres are situated in it. In the interior of the rod we have the stationary condition mentioned. But at the surface, as at the surface of a liquid, a projection of specially swift electrons is possible, where otherwise no impediment exists. Such an impediment is air or a vacuum, and a dielectric generally which surrounds the magnet, since the protrusion of negative electrons at once produces an enormous difference of potential which prevents the projection of further electrons. At the polar surfaces themselves, as we see, no projection of electrons may be expected. A magnetic rod immersed in a dielectric loses, therefore, nothing of its energy.

This conclusion loses nothing in validity when the magnetic rod is magnetised in any manner, instead of being longitudinally magnetised.

The difference of potential appearing at the surface of a magnet at right angles to the magnetic lines of force represents an E.M.F. acting similarly to Volta's force, and capable of superposing itself upon the latter. That it exists has already been proved by the demonstration of the E.M.F. due to magnetisation. We refer specially to the more exact measurements of Hurmuzescu.* Two iron wires, 1mm. thick, and polished at the ends with emery paper, were inserted into the branches of a U-tube. One of the branches was placed between the poles of a strong electromagnet. The tube was filled with a solution of acetic or oxalic acid. The electrode normal to the magnetic field only touched the liquid at its lower end. As a result, it was found that the magnetised electrode was always negative as compared with the unmagnetised one. The direction of the field was immaterial. The curve of E.M.F. in terms of H resembles the curve of magnetic intensity in terms of H.

These results are a simple consequence of our hypothesis. One of the electrodes is magnetised transversely. Hence electrons are projected from its surface touching the liquid, and they change the liquid negatively. Owing to the conductivity of the acid and of the rest of the circuit the difference of potential is at once equalised, and a current is generated, the magnetised electrode forming the positive pole. That the direction of magnetisation is without influence is obvious, as also that the E.M.F. must increase with the magnetisation until saturation is attained.

The results of other experiments made by Hurmuzescu may be similarly predicted from the hypothesis. Thus, for instance, the electrode to be magnetised was entirely covered with an insulating layer, and only in the centre of its length a small round surface of the size of the cross-section of the wire was bared, so that the electrode when immersed in the acid was only touched by the liquid in that small surface. The electrode was again magnetised transversely, but placed so that at one time the normal of the bared surface was perpendicular to the magnetic field, and at another time parallel to it. The magnetised electrode was again the positive pole, but the E.M.F. differed with its orientation. In a field of 5,320 units the E.M.F.s were—

First position.....	114×10^{-4} volts.
Second position.....	19×10^{-4} volts.

Such a result may be expected from the theory. In the first case, the orbits of the electrons are normal to the bare surface, and can therefore emerge along its whole extent. In the second case, the orbits lie nearly all in the free surface. If this were plane, no electrons could emerge; but it is somewhat curved, and so some projections are possible. Under equal conditions, the E.M.F.s should be as the projections of the surfaces upon a plane containing the direction of the field and the axis of the electrode. In another experiment, the electrode last described was placed parallel to the lines of force. Hence the orbits were normal to the bare surface, and could emerge. As a matter of fact, the results were the same as in the first case of transverse magnetisation, where the liquid only touched the terminal surface of the electrode, though not so regular.

ALTERNATING-CURRENT INDUCTION MOTORS.*

BY A. C. EBORALL.

(*Continued from page 644.*)

With regard to squirrel-cage rotors, and to the modification of them, the rotor wire-wound with closed coils, there is not much to say. The chief difficulty with the former lies in the fact that it is difficult to make a good mechanical job of the connections to the end rings. If the rotor bars are screwed to these rings the contact between bar and ring is not only uncertain, but however good it may be at first it is certain to deteriorate under the influence of the heavy rotor currents and the heating and cooling of the rotor. Consequently, most makers sweat the rings over the projecting and flattened ends of the bars. But with this the rings will sometimes melt right off under overload, splashing the solder all over the stator coils, and generally doing other damage. The author's firm braze the rings on, when a motor of this character is put to work of an exceptionally heavy nature, where overloads are the rule and not the exception, or when the starting conditions are severe. Messrs. Kolben get over the difficulty in the manner shown in Fig. 6; here the rotor bars are connected to the short-circuiting rings by means of thin copper strips, used as radial connectors. The rings themselves are of bronze, and are of small diameter, but very massive; they are keyed directly on the shaft without any insulation whatever. In a communication to the author, Mr. E. Kolben states that he has found this construction to prevent entirely the evil mentioned above, and that it greatly assists his single-phase motors to start well—doubtless on account of the extra resistance in the strips. Mr. Kolben also uses this construction for larger motors for crane and similar work (where large starting torques are required without, if possible, the employment of a starting resistance) as it allows of the insertion of the resistance strips of brass or other material, in place of the copper connectors. Several firms, notably the Oerlikon Company, avoid the squirrel-cage construction altogether, by winding the rotor with closed coils. In this case the rotor winding may either consist of a regular wave winding, taken all the way round either once or else several times and finally short-circuited, or better, of a number of coils, or groups of coils, separately short-circuited. Such wire-wound rotors are naturally more expensive than either of the forms described above, and are frequently difficult to wind, on account of the trouble experienced in handling the heavy conductors. The employment of wound rotors and non-inductive starting resistances is, as already indicated, always preferable for motors of any size. Here the rotors are invariably wound with a three-phase star-connected drum winding, which may be carried out either with overlapping (rectangular) coils, or with two or four bars per hole or slot, arranged as a cylinder wave-winding.

The common junction to the three phases of such a winding is frequently the iron-work of the rotor; this is very convenient with motors of considerable size, where the conductors are usually massive. Star-connected bar-windings of this character are always unsymmetrical, and "false connections" have to be made in each phase.

A point to be remembered when designing wound rotors for high-tension motors is the fact that the rotor volts per phase (that is, the voltage between any two slip-rings at normal stator pressure when the brushes are lifted off and the motor is at rest) must be kept down to a safe value: this is because at starting, with all resistances in, the voltage across each resistance (and the corresponding two rings) may be sufficiently large to be a source of danger to the attendant, if the turns in the winding have not been kept down; moreover, there is some risk of arcing taking place. On the other hand, in no case must the number of rotor conductors in series be too few, especially if the motor is of large size, else the cost of the starting box becomes excessive, and, if this latter is mounted on a switchboard, the three heavy cables coming to the latter may become inconvenient to arrange for; moreover, the contacts on the box may give trouble. It may sometimes happen that it is desirable to regulate the speed of a polyphase motor (by means of the rotor resistance) at a point situated a considerable distance away from the motor; in such a case, and if the motor is for a low voltage, it may pay to arrange the rotor windings to transform up, as it were, in order to effect a saving on the cost of the three cables, coming from the rings to the starting box, but this must not be pushed too far. Although it is the standard practice with one or two firms to build the starting resistance within the rotor itself, instead of employing a separate starting box and slip-rings, it would seem that the latter practice is the better. The advantage of doing away with the external arrangement consist, of course, in getting rid of the sliding contacts; on the other hand, it is easy for the short-circuiting device (whether operated by hand through the hollow shaft or automatically) to get out of order, inspection of

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

the contacts is difficult, and, above all, the motor is brought up to speed abruptly, because a subdivided resistance is practically out of the question. Consequently, the effect on the pressure regulation of starting a motor so fitted under heavy load is bound to be greater than if the motor had been fitted with an external graduated resistance, permitting of easy and gradual starting. However, several firms are now engaged in studying this detail, and considerable improvements may be expected shortly in the electrical and mechanical design of internal starting gear.

C. *Notes on Performance and Design.*—An analysis of the guaranteed performance of a given line of open or semi-enclosed induction motors between 2 B.H.P. and 100 B.H.P. built by any of the best Continental or American makers, and whose construction is on the lines indicated above, may be set forth as follows :—

1. No-load Current. Expressed as a percentage of the full-load current, the values for this will be as under :—

	Polyphasers.	Single-phasers.
For motors between 2 — 5 B.H.P. inclusive	30% ...	40%
Ditto 7½— 20 ditto	25% ...	30%
Ditto 25 —100 ditto	20% ...	25%

2. Overload Capacity. This is sensibly the same for all sizes with a given line of motors run at constant stator pressure, and will be as follows :—

	Polyphasers.	Single-phasers.
For one hour*	50%	Varies considerably,
Before falling out of step...	90%	but generally small.

3. Full-load Drop of Speed (Slip). At constant pressure on the stator terminals this will be :—

For induction motors between 2 — 5 B.H.P. inclusive	7%
Ditto 7½— 15 ditto	5%
Ditto 20 — 40 ditto	4%
Ditto 50 —100 ditto	3%

4. Heating. The final temperature-rise after a long continuous run at full load will not exceed 40°C. for semi-enclosed motors having outputs between 2 B.H.P. and 125 B.H.P., and 30°C. for larger sizes.

5. Full-load Efficiency. For semi-enclosed motors with hot windings the values for five representative sizes will be as follows :—

	2	5	10	25	50 B.H.P.
Polyphase motors ...	75% ...	79% ...	85% ..	87% ...	90%
Single-phase motors...	73% ...	77% ...	83% ...	86% ...	89%

6. Full-load Power-factor. The values for this quantity for five such representative motors will be :—

	2	5	10	25	50 B.H.P.
Polyphase motors ...	78% ...	80% ...	85% ...	87% ...	88%
Single-phase motors ...	72% ...	75% ...	80% ...	83% ...	85%

7. Weight per B.H.P. The net weight per B.H.P. (that is, not including the weight of the rails, pulley, and starting resistance, if any) of the five representative motors designed and constructed on the above lines will not come out much below the following values :—

	2	5	10	25	50 B.H.P.
Polyphase motors	80 ..	58 ...	56 ...	40 ...	40lbs.
Single-phase motors	115 ...	88 ...	66 ...	62 ...	62 „

NOTE.—The values given in Nos. 1 to 7 above are for 50-cycle motors at voltages of 110, 220, 440, or 500 volts, having the following number of stator poles per phase :—

All motors between	2—7½ B.H.P. inclusive,	four poles.	
Ditto	10—30	ditto	six „
Ditto	40—100	ditto	eight „

The various values, however, for 40 and 60 cycle motors having the same number of poles are practically the same as those given above. A standard line of induction motors constructed on the lines already indicated, and to which the above figures relating to performance apply, would have the following general technical data.

1. Peripheral Speeds :—4,000ft. to 7,000ft. per minute, according to the size of the motor.

2. Ampere-conductors per inch of stator (inner) periphery at full load.

B.H.P.	Ampere-conductors per inch.
2 to 7·5	250
10 to 30	330
40 to 100	430
100 to 150	570
Above 200	600

3. Flux densities per square inch. In the stator teeth :—

B.H.P.	Maximum value of B.
2 to 7·5	65,000
10 to 30	70,000
40 to 100	80,000
Above 100	85,000

In the rotor teeth :—

B.H.P.	Maximum value of B.
2 to 7·5	80,000
10 to 30	85,000
40 to 100	90,000
Above 100	100,000

In the air-gap the flux-density should never exceed 30,000 lines per square inch. The flux-density in the stator core is determined solely by the permissible loss, and does not otherwise affect the performance of the motor. The above figures give very good results for 50 ∿ motors having partly closed slots for both rotor and stator. With motors for higher frequency, and for hole-wound stators and rotors, smaller values must be taken.

4. Current Densities per square inch. With low and medium pressure semi-enclosed motors, the amperes per square inch in the stator windings at full load will be between 1,500 and 1,100, according to size, while in the rotor bars the current density will be about 15 per cent. higher. With high-pressure motors, somewhat smaller values must be taken in the stator on account of the relatively larger space taken up by insulation.

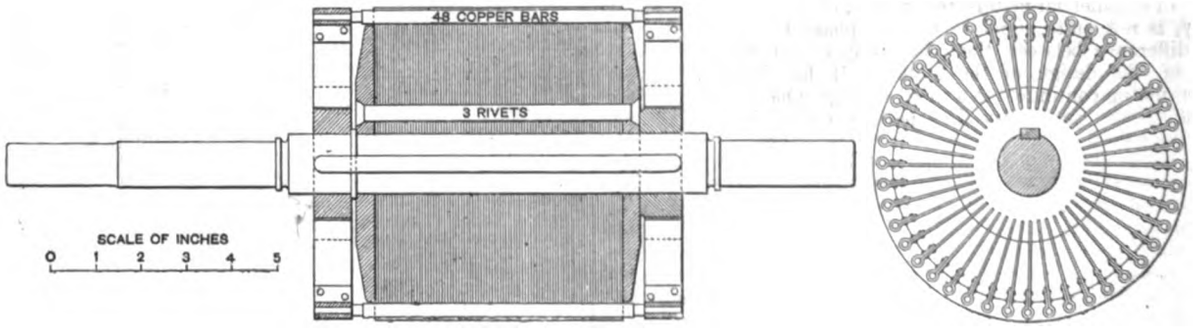

FIG. 6.

5. Length of Air-gap. This is always to be made as small as possible, and is determined wholly by mechanical considerations. Usual values for the length of air-gap, that is, the distance from iron to iron, are :—

Rotor diameter.	Air-gap length.
Up to 4 inches inclusive	1/100 inch.
Between 5 and 8 inches inclusive.....	1/75 „
„ 9 and 12 „	1/50 „
„ 15 and 20 „	1/32 „
„ 24 and 32 „	1/16 „
„ 40 and 60 „	1/8 „

Although the above figures relating to the design of induction motors have been taken wholly from practice, it is perhaps necessary to point out that it is not possible to apply hard and fast rules and constants when designing such motors—experience in designing and a large quantity of experimental data for the type in question are absolutely necessary if the best results are to be obtained.

PART II.—STARTING DEVICES FOR SINGLE-PHASE INDUCTION MOTORS AND SOME NOTES ON RECENT DEVELOPMENTS.

It is not too much to say that more attention has been given to the question of starting devices for single-phase induction motors than to any other problem connected with single-phase working. The first difficulty was to get such motors to start at all; then after this was overcome, there came the question of reducing the heavy starting current; finally, it was sought to so improve the starting device as to permit of the motor starting against load, still with a moderate current consumption. In the six years during which the subject has been before electrical engineers, successive improvements have taken place, and it is to the latest development in single-phase motors that the author wishes more particularly to refer in this part of his Paper, namely, the new motor

* The temperature rise not exceeding 70°C. for semi-enclosed motors, and less for open-type motors.

Digitized by Google

of Mr. Alex. Heyland. Before doing so, however, it may perhaps not be out of place to consider very briefly the underlying principles of all single-phase induction motors, although, of course, there is nothing new to be said on the subject in these days. It has already been stated that a single-phase induction motor is nothing more than a polyphase motor running on one phase. Let, for instance, a two-pole two-phase motor be running from two-phase mains without load. Neglecting (as may quite well be done) the trifling power current required to make up the motor losses (under these circumstances practically only iron, ventilation and friction), the current read on a amperemeter in each phase is the "magnetising current" of that phase of the motor—that is, it is the wattless current required for driving the magnetic flux through the magnetic circuits of the motor; further the speed is synchronous. Now let one phase be switched out. The motor will go on running as a single-phaser at practically the same speed, but the amperemeter in the remaining phase will read approximately twice the current that it did before—that is, the magnetising current in this phase has doubled. What has happened is briefly as follows: The magnetic flux originally provided by the switched-out phase is now replaced by a flux of approximately the same value and relative position furnished by a magnetising current in the rotor. Magnetising currents are called into being in the rotor, induced by the magnetic flux of the phase still connected to the mains, and in quadrature with this flux with regard to time, and these currents are carried round nearly 90deg. in space by the practically synchronous rotation before reaching their maximum. Thus the cross-flux produced by them has very nearly the same effect as that formerly produced by the switched-out phase. The magnetising current in the rotor has, of course, to be balanced by a corresponding stator current, so that the amperemeter reads the magnetising amperes of phase 1, plus the magnetising amperes of the rotor transferred to the winding of phase 1. Hence the magnetising current in the latter approximately doubles. With this perfect motor running at synchronous speed, it would be found that a voltmeter connected to the terminals of the switched-out phase would give a reading equal to the pressure on the mains on which phase 1 is running. This E.M.F. is that induced by the cross-magnetisation of the rotor magnetising currents, and is in quadrature with the impressed E.M.F. of phase 1, as already stated. In commercial motors the E.M.F. of phase 2, measured in this way, is not quite equal to that of phase 1. The magnitude of the difference between the two voltages is a measure of the quality of the design of the motor. It has been said above that the motor continued to run as a single-phaser at practically the same speed. In reality the speed is a trifle less (the difference being too small to detect on a counter), owing to the fact that the rotor currents cause a slight slip, so that even a single-phase motor without friction and ventilation losses (unlike the polyphase motor) cannot run at a synchronous speed at no load. Of course, as the rotor is loaded, the rotor power currents called into being by the load are magnetically balanced by corresponding stator currents (when the rotor and stator coils are co-axial, or approximately so) and the slip increases, that is, the speed departs more and more from synchronism. Owing to this latter circumstance the induced rotor magnetising currents are carried round in space less than 90deg.; the cross-magnetisation produced by them is accordingly shifted from the most effective position, until with continually increasing load there comes a point at which the torque due to the cross field and the rotor load currents attains a maximum value—if this value is exceeded the motor pulls up. When the rotor is stationary, the cross magnetisation is reduced to zero; there remains now only the one flux of the phase connected to the mains (phase 1), and this flux cannot possibly produce a torque—that is, the motor cannot start—because its axis (that is, the axis of the exciting coils of phase 1) coincides with the axis of the current-carrying coils of the rotor. In order, therefore, to enable a single-phase induction motor to start at all, an auxiliary starting field must be created that will do exactly the same thing as the rotor magnetising currents do at synchronous speed. That is, with regard to space, a magnetic flux must be established in quadrature with the principal flux inducing the rotor currents; and with regard to time, this auxiliary flux must coincide with the rotor load current—that is to say, it must be approximately 180deg. behind the corresponding stator current. Every single-phase induction motor must therefore be provided with a device to produce a suitable cross-flux in the air-gap, and the amount of starting torque available will depend purely upon the value of this cross-flux, and upon the effectiveness of its time relations as stated above.

All single-phase induction motors are provided with starting coils wound in the useless winding space of the stator. They rarely occupy more than one-third of the total stator winding space, and frequently less; moreover, these coils are invariably so arranged that the magnetic axis of each coil is in quadrature* to the magnetic axis of the corresponding running coil—a disposition exactly fulfilling the "space" requirement stated above. The difference existing between the various starting devices lies mainly in the various methods of producing the requisite phase relation of the cross-magnetisation.

With the exception of the Heyland motor, all the devices employed for producing this requisite phase difference are external to the motor, and they have all been devised at one time or another by Mr. C. E. L. Brown, and have gradually been adopted by all other single-phase motor builders. These external starting devices take the special form of arranging that the self-induction of the circuit, including the starting coils, has a much higher value than that of the circuit containing the running coils, this being attained by suitable winding proportions in conjunction with choking coils or non-inductive resistances, or condensers; or any two of these in one or other of the stator circuits. The choice of such apparatus is governed by the relative value of the turns in the starting and running coils, and by the particular connections used at starting. The starting torque given by motors arranged in this way is inconsiderable, barely sufficient in fact to run the motor up to speed against the load of belt and loose pulley. Moreover, unless the motor is very carefully designed—particularly from the magnetic leakage point of view—the starting current at this small torque will be excessive. With the above-named exception, the very best single-phase induction motors of the present day working under the most favourable conditions require a current at starting at least equal to the full-load current in order to run them up to speed without the load, while against the full load they will not start at all, whatever the value of the starting current. The principal reasons for these comparatively indifferent results are, that the phase difference at starting produced by the above-mentioned means is small, and

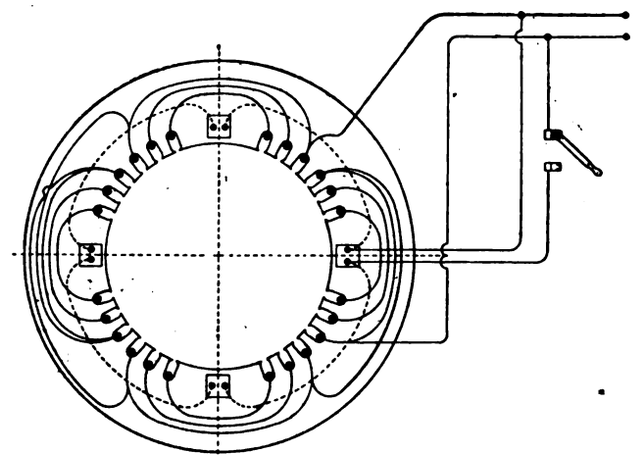

Fig. 7.

that the cross-flux produced by the starting coils does not attain a high value. As with independent alternating-current circuits a large phase difference will be produced by increasing the self-induction of the circuit, it might be thought that this could also be obtained in a motor by arranging the starting device and starting coils on these lines. But it must be remembered that the stator circuits of an induction motor are not really independent, on account of the action of the rotor currents. These behave with regard to the stator currents just as the loaded secondary of a transformer behaves with regard to the primary—that is to say, the self-induction of the stator windings is more or less completely wiped out by the mutual induction of rotor and stator. It follows from this that better results will be obtained if the number of turns of the starting coils is kept low, and the increase of self-induction produced by an external choking coil, or equivalent device involving magnetic leakage. This point was recognised at an early stage by motor builders, and an external choking coil (to produce as much phase difference as possible) is a leading feature of several modern starting devices. But this increase of self-induction, whether produced externally in this way, or by winding the starting coils with a large number of turns, effectually prevents the starting field of the motor (that is, the field in quadrature position to that of the stator running coils) from attaining that high value already shown to be absolutely necessary if a large starting torque is required. Where the self-induction is increased by increasing the turns of the starting coils, the strength of the cross-flux falls off inversely as the square root of the self-induction; if the choking coil is used, the strength of the cross-flux is diminished by an amount equivalent to the leakage flux of the coil. Consequently, it is evidently a clear fundamental point, that to obtain a large starting torque the self-induction of the starting coils should be kept down as much as possible.

*A notable exception to this disposition is the arrangement that has been used for many years by the Swedish firm of Wenström for their small single-phase motors, which have the starting coils "staggered" from the position indicated here.

Digitized by Google

It has been hitherto generally held that the design of starting devices for single-phase induction motors should be such that the starting conditions should approximate as nearly as possible to the starting conditions of polyphase motors—that is, designers have aimed at the production of a rotary field at starting. Not only this, but every effort has been made to make this field as uniform as possible, by so proportioning the windings of starting and running coils as to produce two equal magnetic fluxes, and the production of a larger field by one or the other winding has been particularly avoided. Mr. Heyland's motor, which is shown here to-night, and described below, is designed with regard to the starting device on exactly opposite lines to these. Briefly, there is no external phase-shifting device, the starting winding being put straight on the mains, and this winding has comparatively few turns, and is so arranged that under all circumstances its self-induction is less than that of the running coils—that is, the winding carrying the current of greater phase-difference is made to have the smaller self-induction. As a result of the small self-induction of the starting coils, a cross-magnetic flux of great strength is available, and this cross-flux is made to have the proper time relation by a special arrangement of the magnetic circuit of the stator. The production of a rotary field at starting is not aimed at, the whole idea of the starting device being to produce a powerful alternating magnetisation having the proper phase relation in a direction (considering the two-pole case) at right angles to the axis of the running coils. The result is that the Heyland single-phase motors will all start against full load quite easily without an excessive current consumption, and it will be, therefore, readily admitted that an important advance has been made in single-phase motor work.

Apart from the design and arrangement of the starting device, the Heyland motors differ but little from other well-designed motors of the induction type. The stator-running winding consists of a number of rectangular coils wound in half-closed slots in such a manner that magnetic leakage is as small as possible, while the rotor is wound with a regular three-phase star-connected winding, with its three free ends connected to slip-rings on the shaft, for the insertion of a starting resistance. A squirrel-cage rotor, or one of its modifications, could be easily used, but it has been found that the reduction of the starting current (for a given torque) brought about by the use of the resistance well repays its use, even for motors as small as 1 H.P. Fig. 7 illustrates diagrammatically the stator windings of the Heyland single-phase motors, the figure illustrating a four-pole motor. The running coils are shown by the full lines, and the starting coils by the dotted lines. These latter coils are wound in rectangular holes in order to obtain the necessary large phase difference of the current in them; the flux produced by these coils links very unfavourably with the rotor windings, which has the effect of reducing the mutual induction of the circuits in question, with the result that the current in the starting winding lags considerably, sometimes as much as 50deg. The relation of the stator starting coils to the

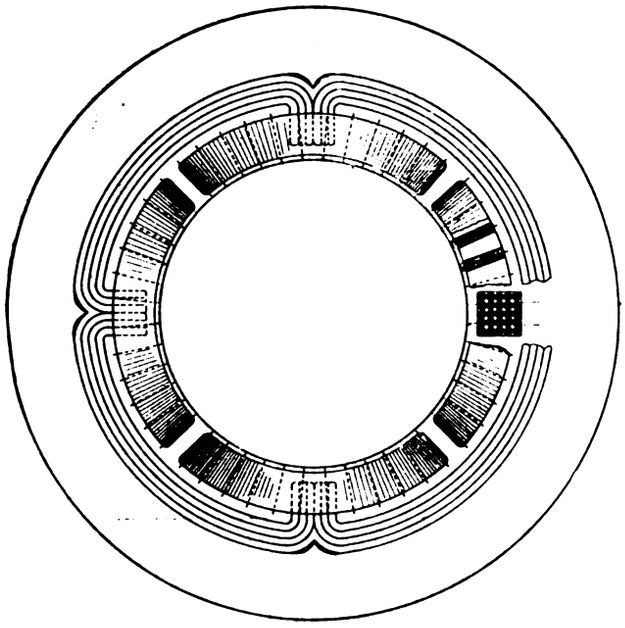

FIG. 8.

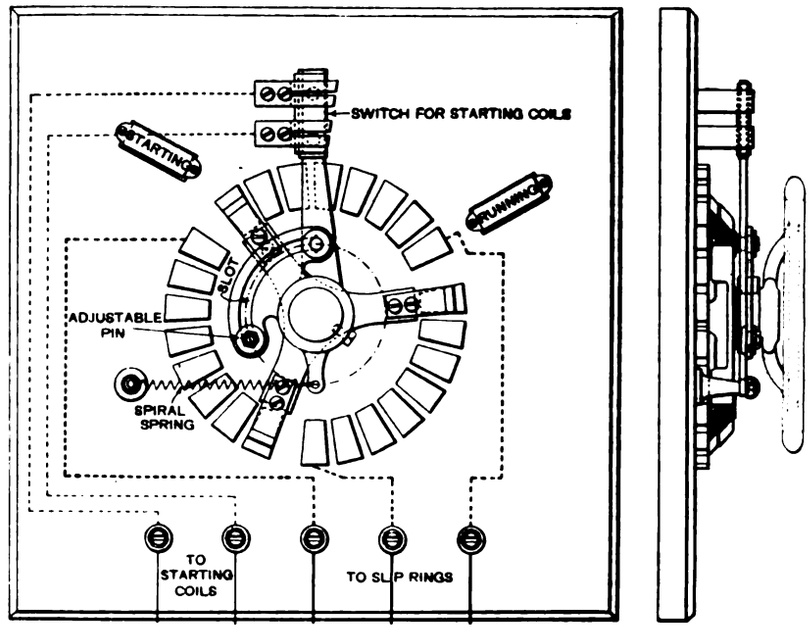

FIG. 10.

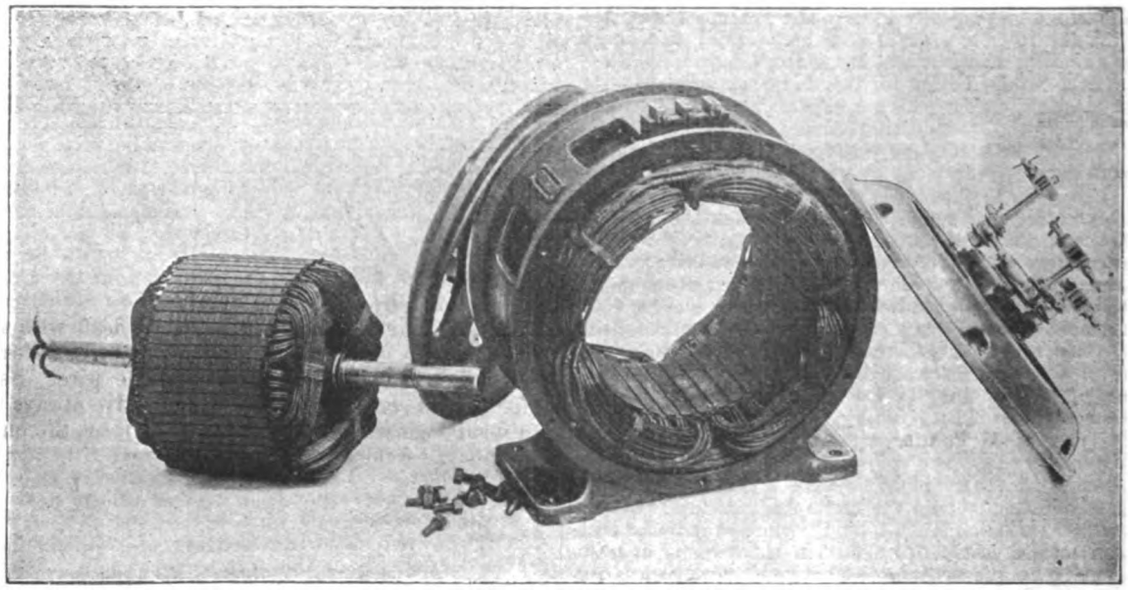

FIG. 9.

Digitized by Google

coils of the rotor is in fact entirely analogous to the relations existing between the primary and secondary coils of a transformer having great magnetic leakage. As stated above, the turns of the starting coils are comparatively few in number, and have a low resistance; the amount of phase difference of the flux produced by the current in them is determined by the shape given to the holes, the dimensions of these, and by the winding depth. Fig. 8 and Fig. 9 show clearly the arrangement of the stator running and starting coils as actually carried out for a four-pole motor, while the form of the rotor winding can be seen from the latter figure also.

The motor is started as follows:—All the rotor resistance being in circuit, the stator windings (both running and starting) are switched directly on the mains; the motor will immediately start up with great torque, and the rotor resistance and starting coils are to be cut out as it does so. The exact moment at which the latter are cut out affects only the starting current: if the motor is starting light, the single-pole switch can be opened when the arms of the rotor resistance are on the second contact; if it is starting against full-load, the starting coils require to be left somewhat longer in circuit—that is, they are to be cut out, for instance, on the fourth or fifth contact of the starting resistance.

The earlier Heyland motors were all furnished for use with a single-pole switch in the starting circuit. This has now been done away with, however, by combining it with the starting resistance box (see Fig. 10), so that the operation of starting up is as simple as that with a shunt-wound direct-current motor.

(To be concluded.)

PARIS EXHIBITION AWARDS.

Below is a list of the principal medals and awards made to British exhibitors of electrical and scientific specialities at the Paris Exhibition:—

GROUP III.—Class 11 (Typography, &c.).

Bronze Medal.—A. W. Penrose & Co., London, W. (photo-engravers' finishing machinery, photographic arc lamps, &c).

Class 12 (Photography).

Grand Prize.—Royal Observatory. (See Class 14.)

Gold Medals.—A. W. Penrose & Co. (see Class 11) and Newman and Guardia (kinematographs, &c.).

Silver Medals.—Dr. J. M. Davidson (X-ray photographs), and F. H. Glew (X-ray and lightning photographs).

Bronze Medal.—G. Corden (photographs of lightning), B. Molesworth (telephotographs), S. Webb (photographs of lightning), and R. N. Wolfenden (X-rays applied to zoology).

Class 14 (Maps, &c.).

Grand Prize.—Royal Observatory (magnetic records, &c.).

Gold Medal.—Prof. A. W. Rücker (magnetic survey maps).

Class 15 (Mathematical and Scientific Instruments).

"Hors Concours."—Sir W. Abney (colour photometer), Mr. C. Vernon Boys (constant of gravitation apparatus, radio-micrometer and quartz fibre), Sir W. C. Roberts-Austen, K.C.B. (recording pyrometer), and Prof. J. J. Thomson (apparatus for measuring the velocity of the cathode rays).

Grand Prizes.—Board of Trade Gas Referees (pentane table, photometer), and the Cambridge Scientific Instrument Co. (electrical and other instruments).

Gold Medals.—James J. Hicks (electrical and scientific instruments), Negretti and Zambra (electrical and scientific instruments), W. Watson & Son (scientific instruments).

GROUP IV.—Class 19 (Mechanical Engineering).

"Hors Concours."—Thwaites Bros. (blowers, steam hammers, and centrifugal pumping engine).

Grand Prizes.—C. A. Parsons & Co. (steam turbines), Willans and Robinson (2,400 H.P. central-valve triple expansion steam engine coupled direct to a Siemens continuous-current dynamo), and Galloways (Ltd.) (boilers and vertical compound engine).

Gold Medals.—Marshall, Sons & Co. (compound steam engine), Ruston, Proctor, & Co. (steam engines), Ransomes, Sims and Jefferies (steam engines), and R. Garrett & Sons (boiler and steam engines).

Silver Medals.—Robey & Co. (compound horizontal engine coupled direct to 350kw. electric generator), E. Green & Son (fuel economisers), G. and J. Weir (feed pumps, &c), and Patent Exhaust Steam Injector Co. (injectors, &c.).

Bronze Medals.—James Proctor (stokers), Tangyes Limited (steam engines, &c.), and Deighton's Patent Flue Tube Co. (flues).

Class 20 (Various Types of Engines).

Grand Prize.—Crossley Bros. (gas engines).

Gold Medals.—R. Hornsby & Sons (Hornsby-Akroyd oil engines), Priestman Bros. (oil engines), Campbell Gas Engine Co. (gas engines), National Gas Engine Co. (gas engines), and Tangyes Limited (gas and oil engines).

Silver Medals.—Ruston, Proctor & Co. (oil engine), Dudbridge Iron Works (gas engines and oil engines), Robey & Co. (winding engines, &c.,) Blackstone & Co. (gas engine and oil engines), and J. and F. Howard (oil engines, &c.).

Bronze Medals.—R. Cundall & Sons (oil engine), A. Dougill & Co (gas and oil engines), and Duke and Ockenden (wind motor).

Class 21 (General Machinery).

"Hors Concours."—Thwaites Bros. (See Class 19).

Grand Prize.—Merryweather & Sons (fire engines, &c.).

Silver Medals.—Mather and Platt ("Grinnell" automatic fire extinguisher and alarm, &c.), G. Salter & Co. (spring balances, dynamometers, tension ratchets for telegraph wire, &c.), Mossberg Roller Bearings, Ltd., (roller bearings), J. J. Stockall & Sons (automatic alarm clocks, &c.).

Bronze Medals.—Samuelson & Co. (blowers), and Roller Bearings Co. (roller bearings, &c.).

Class 22 (Machine Tools).

"Hors Concours."—Thwaites Bros. (See Class 19.)

Grand Prizes.—Smith and Coventry (planers, lathes, chucks, gauges, &c.) and Mather and Platt.

Silver Medal.—Robey & Co.

Bronze Medal.—Belshaw & Co.

Class 23 (Mechanical Production and Utilisation of Electricity).

Grand Prize.—Siemens Bros. & Co.

Gold Medals.—C. A. Parsons & Co., and Mr. Duddell (Cambridge Scientific Instrument Co.).

Silver Medal.—Mr. Wm. Burton (James J. Hicks).

Class 24 (Electro-Chemistry).

Gold Medals.—Electrical Power Storage Co. (storage batteries), Chloride Electrical Storage Syndicate (storage batteries), and S. Cowper-Coles (specimens of electro-deposited metals, &c.).

Class 25 (Electric Lighting).

Gold Medals.—W. A. S. Benson & Co. (electroliers and accessories), and Simplex Steel Conduit Co. (Simplex steel conduit system-tubes, bends, &c.).

Silver Medal.—Belshaw & Co. (switches, fittings, &c.).

Class 26 (Telegraphy and Telephony).

Grand Prize.—G. P. O. (telegraph instruments and apparatus).

Silver Medal.—Patent Nut and Bolt Co. (bolts, nuts, screws, &c.).

Class 27 (Various Applications of Electricity).

Grand Prize.—James White (collection of Lord Kelvin's electrical instruments).

Gold Medal.—Crompton & Co. (potentiometers, standard resistance, Hibbert's 1-volt standards, electric thermometers, &c.).

Silver Medals.—James J. Hicks (electric anemometers, battery hydrometers, electric thermometers, &c.), and J. J. Stockall & Sons (electric clocks, alarms, &c.).

Class 28 (Civil Engineering. Transportation).

Gold Medals.—Jessop and Appleby Bros. (crane), Grafton & Co. (crane), Temperley Transporter Co. (model of traveller), and Ruston, Proctor & Co.

Silver Medals.—A. C. Wells & Co. (the "Wells" light, waste oil filters, &c.), and Hardy Patent Pick Co. (mining tools, &c.).

CORRESPONDENCE.

ELECTRICAL CONDUCTORS AND DIRT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read Prof. F. G. Baily's interesting article in your issue of the 10th inst. Though he appears to think so, there is not any difference between us. In my Paper published in your issue for April 27th., I dealt with a specific case where the supply was afforded by the Westminster Company who do not earth their middle wire. As I have pointed out, in such an instance the negative always tends to earth itself; consequently, the positive wire is the one that is at the greatest difference of potential from earth. In the case alluded to by Prof. Baily the middle wire was earthed at the station, so that it would always be the other two wires that would be at the greatest difference of potential from earth. The potential would of course be negative in the case of one wire and positive in the case of the other.

I have never suggested that dirt accumulates more rapidly upon a positive wire than on a negative one merely because of its sign. It is, however, the case that it does so in instances where the middle wire is not earthed, as is at present, I believe, usually the case, at any rate, in London. As pointed out in my Paper, the necessary requirement in order to keep conductors and fittings clean is to maintain them as nearly as possible at earth potential.—Yours, &c.,

London, S.W., Aug. 17, 1900. A. A. C. SWINTON.

LEGAL INTELLIGENCE.

National Telephone Co. v. Clontarf and Hill of Howth Tramway Co.

In the Vacation Court, Dublin, on Wednesday, before Mr. Justice Barton, application was made by the plaintiff company for an order restraining defendants, their servants, agents and workmen, pending the hearing of an action, from interfering with the wires of the plaintiffs' system of telephonic communication between Dublin and Howth by placing their tramway trolley wires in such close proximity to plaintiffs' wires that they were precluded from working their telephone system with efficiency. The act under which the tramway from Dollymount to Howth was constructed contained provisions that they should carry out the work so as not to interfere with the working of the telephone system. What the National Company complained of was that the Tramway Company had placed their trolley wires in such close proximity to the telephone wires that the telephone system had been subject to frequent interruptions. It was alleged that in three places (and this was not denied) the Tramway Company had actually placed their wires in mechanical contact with the wires of the National Company, the result being that the electric current of the tramway system was transferred to the telephone wires, which were in danger of being fused along the whole system and rendered useless. Plaintiffs invited defendants to have the matter referred to an arbitrator appointed by the Board of Trade, but this offer was declined by defendants, who had practically said that plaintiffs, if they had any legal remedy, must enforce it. An affidavit by Mr. F. Gill, superintendent for Ireland of the plaintiff company, was read by Mr. O'Connor, Q.C. (for the plaintiffs), who said that what plaintiffs complained of could be remedied quite easily, and he asked that the injunction should be granted.

Mr. CAMPBELL, Q.C., M.P., replied for the defendant company, and said they had got the Board of Trade certificate that the line had been constructed in compliance with requirements. By sec. 55 sub-sec. 2 of the Tramway Act, if defendants' lines improperly interfered with the telephone wires they could remove their wires to another place and make the defendants pay the cost, which, according to a letter written by Mr. Dillon (plaintiffs' solicitor) would only amount to £42. Instead of that simple remedy they came into Court with a ridiculous suit in Chancery.

Mr. JUSTICE BARTON said at first sight the application seemed a very urgent matter, but it was admitted on both sides that plaintiffs themselves could to-morrow, at the cost of between £40 and £50, set this matter right. It was their own poles, not those of the defendant company, that seemed to be the poles which ought to be removed, and of course plaintiffs could recover the cost of that removal from defendants if it turned out in the end that they were in the right and defendant company in the wrong. That being so, the question of urgency disappeared, and his lordship refused the application, but reserved the question of costs.

Moon, Loughlin & Co. v. Pye.

At the Blackburn County Court on Monday, Messrs. Moon, Loughlin & Co. sought to recover from Mr. Pye, engineer, Blackburn, £18. the price of a dynamo. Plaintiffs received an order from Messrs. Clark & Co., Hanley, for a dynamo, and communicated with Messrs. Humphreys & Son, Salford, who referred them to defendant. A dynamo was bought from Pye, and plaintiffs said they paid for it subject to the machine passing the necessary tests. It was alleged that this it had failed to do. Mr. Clark gave evidence and said it was an old machine. One witness said the machine could be made all right for 20s, while another said an expenditure of £5 would make the dynamo as good as new.

The defence was that the machine was not sold as absolutely new, and that when placed on the railway it was perfect.

Judge Coventry gave judgment for the plaintiffs.

MUNICIPAL, FOREIGN & GENERAL NOTES.

Aberdeen.—The Castle-street–Bathing Station tramway route is to be electrically equipped on the overhead trolley system. The existing tramway in Union-street between St. Nicholas and Castle-streets is also to be similarly equipped with side poles and span wires. The burgh surveyor (Mr. W. Dyack) has been authorised to invite tenders for 800 tons of steel rails and 10,000 tons of causeway setts, and the electrical engineer (Mr. J. Alex. Bell) to invite tenders for the tramway poles. The electrical engineer and the superintendent of the tramways are to report as to the type of car to be adopted, and the number to be ordered. Mr. Bell has also been authorised to communicate with the Westinghouse Company in order to ascertain whether they would give a quotation of the cost of electrically equipping the tramway in Union-street on the underground conduit system.

Abertillery.—A resolution to apply for a provisional order has been unanimously passed by the Council.

Antananarivo (Madagascar).—A concession has been granted by the French Government to M. Orville Florens, sen., of Paris, for the supply during 50 years of electric current for lighting and power for Antananarivo and surrounding district. This work is coupled with the supply of water for the same district, and both are to be completed within two and a-half years.

Blackburn.—An inquiry was held here on Friday into the application of the Corporation to borrow £190,000 for extensions of the electricity supply works. The town clerk said it had been originally proposed to ask for over £220,000, but this had been reduced. The electricity works adjoined the No. 1 Gasworks, which were very old and had become too small to meet the needs of the town. The Corporation had purchased land in another part of the town for new gasworks, and when these were completed the whole of the No. 1 Gasworks would be devoted to the generation of electricity. That site had been valued at £30,000. The consulting engineer (Mr. E. M. Lacey) stated that part of the proposed scheme would meet the requirements for the next four or five years. When this was carried out there would be land available for further extensions for the next 15 or 20 years.

Buenos Ayres.—According to the *Review of the River Plate* the electric lighting companies in this city have entered a joint protest against the new tax imposed upon them by the municipality, and which they consider to be a duplicate of another tax. The companies have to pay 5 per cent. of their gross receipts for the use of the subsoil, and this year a tax has been placed on all transformer pits and corner boxes, and this the companies consider to be already covered by the 5 per cent. subsoil tax. The companies intend to test the legality of several other taxes, including this 5 per cent., on the ground that when some of them obtained their concessions the tax was only 2½ per cent, of the gross revenue, and it is argued if the authorities have the right to increase it to 5 per cent., they have an equal right to make it 10, 20 or any other rate.

The directors of the Sociedad Cooperativa Telefonica have issued their report for the year ended June 30 last. The profit on the year's working shows a credit balance of $113,240.69. The company possesses 3,244 metres of underground mains and 42 subterranean chambers and 7,098 kilometres of line. Messrs. L. M. Ericsson & Co, Stockholm, are building multiple boards for the new central office at a cost of $25,000 gold.

Bury St. Edmunds.—The £800 recently borrowed for lighting the roads on the Brown estate is instead to be applied in the lighting of Risbygate-street and St. Andrew street, and in erecting eight arc lamps in the central portion of the town.

Burnley.—An inquiry has been held here into the application of the Council to borrow £1,200 for electric lighting. There was no opposition. The amount of existing loans is £51,250.

Central London Railway.—It has been discovered that the present system of cancelling tickets lends itself to fraud, and the directors are considering how best to obviate this. Electrical communication is being established at some of the stations between the platforms and the booking halls, so that a signal may be made to the lift attendant, indicating the approach of a train, this arrangement being required to regulate the number of passengers to be allowed to descend to the platforms for the incoming train. With the present five-minute service, it has been impossible to avoid overcrowding at the Bank Station at certain periods of the day. On such occasions the 30 seconds allowed for stoppages at the platform has been considerably exceeded, with the result that the journey has been prolonged beyond the scheduled time, and intervals of 10 minutes between the running of trains have occurred. With the introduction of a more frequent service, it is believed that this difficulty will disappear. The daily average number of passengers has already reached a total of nearly 100,000.

Chester.—An inquiry was held here on Wednesday into the application of the Council to borrow £35,000 for electric lighting extensions. The town clerk (Mr. S. Smith) explained that powers had already been obtained to borrow £65,000, and that had been over-expended by about £740. The present loan would be applied in making additions to the generating plant and in extending the mains, &c. The electricity undertaking had been an unqualified success, and they had been able to place £2,465. 1s. 1d. to reserve. They started by supplying current at 6d. per unit, and had reduced the price to 4½d., in addition to allowing large customers considerable discounts. During the year ended March, 1900, the Corporation sold 617,792 units, against 473,656 last year. The Corporation had decided to take over the tramways and though it was not absolutely settled, electric traction would probably be adopted. The Corporation would be able to generate the necessary current at the present station, as provision had been made for doubling the buildings. There was no opposition.

City and Guilds of London Institute.—The programme of technological examinations for the session 1900-1, price 1s. net, is issued by Messrs. Whitaker & Co.

Clydebank.—The Commissioners have decided to apply for electric lighting powers.

Digitized by Google

Colliery Lighting.—At an inquest at Haydock into the circumstances attending the death of eight men who succumbed to injuries received in an explosion of gas in the old Boston colliery, Haydock, the Inspector of Mines (Mr. H. Hall) expressed the opinion that in all sinking operations electric lights should be used. The jury returned a verdict of "Accidental death," and recommended that in future sinking operations should be carried on by electric light.

Crieff (N.B.).—A committee is to report upon the question of obtaining electric lighting powers, or as to allowing the North British Electricity Supply Co. to obtain an order.

Crystal Palace Accident.—The deputy-coroner for West Kent (Mr. E N. Wood) resumed on Friday last the inquest on the bodies of Frederick Elliston (33) and William Philbrook (19), who met their death in a boiler explosion on the premises of the Crystal Palace District Electric Supply Co. on 25th ult. Mr. Walter Phillips, electrical engineer to the company, said that every year until this year the boiler had been thoroughly examined. The reason why it was not done this year was because the company were busy, and could not let the boiler be idle, as the examining process took over a week. Since the explosion he had examined the fragments of the boiler, and found flaws. In his opinion those flaws were the cause of the explosion. The jury returned a verdict that the deceased died from injuries caused by an explosion of a boiler, due to its defective condition, which might have been discovered had the boiler been thoroughly examined.

Customs Decisions.—A recent decision of the United States Customs Board is to the effect that telephone switchboard cables composed of 64 copper strands, each tin coated and cotton covered, wrapped successively with paper, metal foil, paper, cotton thread and insulating material, the wire being the component of chief value, are dutiable as articles manufactured from copper and not under the head of "covered wire."

Derby.—An inquiry was held here on Thursday last into the application of the Council to borrow, among other sums, £730 for purchasing a condenser for the electricity works.

Dewsbury.—The question of extending the electric lighting mains to West-town is under consideration.

Dublin.—At a special meeting of the Council on Monday, the report of the Electric Lighting committee, recommending the acceptance of the tenders for generating plant for the new works at the Pigeon House was discussed. (The tenders are set out in another column.) Exception was taken that the committee's report was being rushed through, but the Lord Mayor pointed out that the report had been in the hands of members for a month, and that a special meeting of the Council had been called to consider it. After some discussion it was agreed that another special meeting should be called for Monday next to finally decide the matter. In the meantime, the secretary of the Dublin United Tramways Co. (Mr. C. W. Gordon), has addressed a letter to the Lord Mayor in which the company's offer to supply electricity "in bulk" is renewed.

The deputation recently appointed to visit Continental cities where three-phase systems of distribution were in operation reported their visits to the Paris Exhibition, Strasburg, Mannheim, Mayence, Frankfort-on-Main, Nuremberg, Prague, and Oerlikon. The general conclusion, the committee reported, to be drawn from their visit, was "that for a combined lighting and motor supply the three-phase system was superior to either the continuous-current or single-phase systems, while if it was desired to supply power for street tramways it was only necessary to combine a three-phase motor with a continuous-current generator of the required voltage. The great advances which had been made in the manufacture of three-phase generators largely contributed to the steadiness of supply under varying conditions, and also simplified the problem of the distributing network. The committee were satisfied the scheme laid down by Mr. Robert Hammond for the supply of electricity to Dublin from the Pigeon House station was one which could be adopted with confidence by the Electrical committee of the Corporation."

Dundee.—The salary of the city electrical engineer (Mr. Walter H. Tittensor) has been increased from £250 to £350 per annum, to be further increased to £400 at the end of twelve months, on account of the extra work entailed by the electric tramways.

Electrical Enterprise in Italy.—The Mediterranean Railway Co., of Milan, have secured a concession from the Italian Government to substitute electric working on the line from Sampierdarena to Rome. The power station will be erected at the former town. The company are about to purchase 23 electric locomotives.

Electric Traction in the Liverpool District.—A syndicate is being formed to promote and construct a series of railways in Cheshire and the Liverpool district, including an electric railway across the estuary of the Dee from a point near Caldy to Point of Air (Flintshire) and on to Rhyl, and an underground electric railway from the Central (low level) Station, Liverpool, to Huskisson Goods Station, and from Central Station to St. James's station. The first line will be about 14 miles long, 5 miles being carried on an embankment and bridge, or on a bridge alone, over the Dee estuary, connection being made with the Wirral Railway and L. and N. W. and G. W. joint railways, near West Kirby, and with the L. and N. W. and the Denbigh and Corwen Railways at Rhyl. The second line will require two tunnels connecting the Cheshire Lines Railway at Huskisson station with the Mersey Railway at Central (low level), running thence to St. James's. The consulting engineer is Mr. R. H. Scotter, of Southport and London, and it it claimed that by the combined schemes much quicker and cheaper access would be afforded between Liverpool and West Lancashire, the North Welsh coast and Ireland, via Holyhead. The electric system would be continued from Huskisson to Aintree, and from Aintree to Southport on the Cheshire Lines and the Southport and Cheshire Lines Extension.

Electricity in Mining.—The electrical transmission plant of the Deep Leads Electric Transmission Co. (Ltd.) (Victoria) has been erected, and two units of 2,500 H P. each are ready. Electric current will be supplied to the entire group of mines in the district.

Exhibition.—In 1901 an extensive exhibition of Russian industries is to be held at Riga.

Glasgow.—At the Corporation meeting last week Bailie Maclay submitted the report of the electricity department, in which the scale of charges for 1900 1 was set out. Bailie Anderson, in criticising the report, said there ought to be, as in Edinburgh, one rate for current for light and one for power, and the large consumer should be allowed a reduction, which should be taken off his account, and not regulated, as at present, by the demand indicator. Bailie Maclay admitted the arrangement was not perfect, and promised that it should be looked into. He afterwards moved the approval of the annual report and balance-sheet of the committee, an abstract of which was given in our last issue. The motion was adopted.

Grimsby.—The Grimsby Street Tramways Co. have let the contract for the erection of electric power station in Cleethorpes, in addition to having purchased new electric cars, at a cost of about £700 each. It is anticipated that by next year the Grimsby and Cleethorpes lines will be working by electricity. The work of laying a double set of rails along Grimsby-road suitable for electric traction will be started in October. The station, which is to be acquired by the District Council as soon as that body has the necessary powers, will be constructed so as permit of considerable extension, the Council intending to provide accommodation for the plant necessary for street lighting by arc lamps. Negotiations for the lighting of the Cliff Gardens, pier, and promenade by electricity are progressing satisfactorily.

Guernsey.—At a special meeting of the States convened for Sept. 3 a proposal will be made to place at the disposal of the Electric Lighting committee £350 to defray the expenses of the consulting electrical engineer (Mr. A. L. Davis) in connection with the electricity supply scheme.

Halifax.—The accounts of the electricity department for the past year have been submitted. The capital outlay is £93,218, an increase of £20,748 on the previous year; the units of current sold, 1,371,333, an advance of 742,574; the gross profit, £9,001, an increase of £4,436, and the average price obtained per unit, after deducting discounts, 2·77d. The cost of production per unit was 1·23d., a reduction of nearly ½d. compared with the previous year's results. The output of the Halifax works (1,371,333 units) was exceeded by only seven stations in Great Britain (excluding London): Liverpool (5,729,477), Manchester (4,773,247), Edinburgh (4.174 541), Brighton (3,206,623), Glasgow (2,824,350), Bradford (2,416,130), and Leeds (1,697,258).

Hotel Lighting.—In consequence of the building of the north block of the Hotel Cecil, Strand, London, the electric lighting installation is being considerably extended, under the superintendence of the chief engineer (Mr. W. A. Poynton), and a fifth 75kw. turbo-dynamo has been ordered from Messrs. C. A. Parsons & Co.

Hyderabad (India).—*Indian Engineering* announces that proposals have been made for constructing an electric tramway between Hyderabad and Secunderabad, and for the supply of current for electric lighting and power.

Ilford.—The foundation stone of the electricity supply station building will be laid to-morrow (Saturday) by the chairman of the council (Mr. H. Weeden, J.P.).

Kingstown (Dublin).—The Council have decided to carry out the terms of their provisional order (obtained in 1896), and the proposed application of Messrs. Porte, Sykes & Co. will consequently be opposed.

Launceston.—Owing to the increase in the price of gas, the leading tradesmen and other citizens recommend the Council to adopt an electric lighting scheme.

Leeds.—The Tramways committee recommend the City Council to promote a bill authorising the extension of the tramway system. Six new tramway routes are proposed.

Digitized by Google

Leeds.—The Corporation are recommended by the Lighting committee to abolish electricity meter rent as from Oct. 1.

Light Railways.—The Board of Trade have, after modification, confirmed the Barnsley and District Railway and the South Staffordshire Light Railway Orders, 1900.

Liverpool.—Electricity is being generated at the new Lister power station both for public and private use.

Llanelly.—The British Insulated Wire Co., which recently acquired the provisional electric lighting order of the Council, has come to terms with the directors of the local tramways company for the acquisition of the undertaking. The lines are to be reconstructed and equipped electrically. Considerable extensions are to be carried out.

Los Angeles (California).—Two companies are engaged in this city in transmitting electric power, one company's source of power being situate 80 miles distant from the point of distribution. The city tramways are worked electrically, the companies owning the lines having altogether 120 miles of track. To increase the water-power facilities a local company is being formed to construct a lake 10 miles long by 2 miles wide and 100ft. deep by means of a dam across the Mojave river at Victor.

Maidstone.—The Council have been informed by the Local Government Board that, while prepared to approve the electric lighting scheme for Maidstone, the Board would like to have the opinion of an independent expert, and it is proposed to ask Sir William Preece to report.

Moss Side.—The following agreement has been entered into between the District Council and the Manchester Corporation in regard to the tramways in the district :—

(1) The Moss Side Council to grant to the Manchester Corporation a 21 years' lease from the expiration of the lease to the Manchester Carriage Co. ; (2) the Corporation to reconstruct at their own cost the tramways owned by the Council, to erect the overhead equipment thereof, to repair and maintain the permanent way and overhead equipment during the lease, to renew the rails during the last six years of the term, and to hand over the permanent way in good condition to the Council at the end of the lease, but the overhead equipment shall remain the property of the Corporation unless the Council determine to purchase it ; (3) the rental for the lines to be at the rate of £400 per mile of single track per annum ; (4) the line in Upper Chorlton-road to be acquired by the Moss Side Council, and to be leased on the same terms as the other lines ; the cost incurred by Moss Side in acquiring and relaying the line to the Manchester specification to be refunded by a series of annual payments during the period of the lease ; (5) the lease of all the lines to terminate at the same time.

Penzance.—On the recommendation of the Electric Lighting committee it has been decided to engage an electrical engineer to report as to the establishment of electricity works.

Russia.—Electric tramways are being constructed at Riga, and the tramways at Libau are already running over a portion of the lines for which a concession has been granted.

Shoreditch (London).—The Vestry have experienced difficulty in regard to outstanding accounts for electric current, wiring and fitting work, &c., and have issued the following rules : –

Weekly Accounts.—Meters to be read, as at present, each Thursday, and demand notes sent to accountant's office same day. Payment to be made by the Friday week following, failing which the collector is to attend at the lighting station, and proceed to the defaulter's premises, together with a representative of the electrical engineer, who will disconnect the supply unless payment is made on demand.

Monthly Accounts.—Meters to be read on last day of each month, and demand notes to be sent to accountant's office same day. On demand notes payment is requested within 15 days, but consumers should be allowed credit to 21st of each month. If payment is not made by that date final notice allowing three days' grace to be served, and in default of payment supply is to be cut off (as above described).

Quarterly Accounts.—Meters to be read as near quarter-day as possible. Demand notes to be sent to accountant's office by 15th of next month. Payment is requested within 15 days on demand notes. In the first week of the last month of the quarter a list of outstanding accounts to be prepared, and defaulters who have not paid by the Friday 14 days before quarter-day are to be served with final notice giving three days' grace, after which supply will be disconnected.

When the supply has been disconnected under these rules all expenses of re-connection to be charged to consumer.

Soul (Corea).—The street railways in this city have now been extended southwards to the river port Riong-Sau, the miles of track opened being 8·77. There are six cars in use, and the number of miles run daily is about 380. The cost of construction of the line, including the telephone service throughout has been 40,000 yen (£4,000) per mile.

South Dublin.—The Council have applied to the Dublin United Tramways Co. for terms for supplying electric current for lighting the districts of Templeogue and Rathfarnham electrically.

Sunderland.—The Tramways committee have decided to invite tenders for the construction of 24 new electric tramcars, bringing the number up to 50.

Taunton.—On Wednesday last week the mayoress (Mrs. W. A. Wrenn) formally started the new machinery erected at the electricity works at a cost of about £5,000. Afterwards the chairman of the Electric Light committee (Ald. W. Potter), who has been from the first connected with the muncipal electricity undertaking in that capacity, and Mrs. Potter, were recipients of a presentation to celebrate the event.

Transmission of Cablegrams by Telephone.—Since 1895 the Liverpool Chamber of Commerce have agitated for an arrangement between the Postmaster-General, the Atlantic cable companies, and the National Telephone Co., whereby cable messages arriving after ordinary business hours (6 p.m.) might be transmitted direct by telephone to addresses, or replies received by the telephone company for transmission abroad by the cable companies. The matter has now been brought to what is described as "a satisfactory issue." The following correspondence has passed between the negotiators :—

From Mr. J. C. Lamb to Mr. C. M'Arthur, M.P. :—

General Post Office, London, August 18, 1900.

SIR: In regard to the proposed use of the National Telephone Co.'s exchange in Liverpool for transmission after business hours of cable messages of that company's subscribers, I am directed by the Postmaster-General to acquaint you that, in compliance with the representations of the mercantile community of Liverpool, he proposes to authorise such an arrangement subject to the acceptance of a suitable licence by the National Telephone Co., and the cable companies concerned. The Postmaster-General did not feel himself in a position, at the present stage, to make any public announcement on the subject. He understands, however, that the letter in which the arrangement was proposed to the National Telephone Co. has been published by that company, and in the circumstances he desires me to enclose for your information a copy of the letter in question. I am to add that the National Telephone Co. and the Transatlantic cable companies have now agreed to the arrangement, and a formal deed embodying the Postmaster-General's licence and the necessary details is in preparation.

(ENCLOSURE.)

General Post Office, London, July 20, 1900.

To the Managing Director, National Telephone Co.

SIR : I am directed by the Postmaster-General to say that, after giving careful consideration to the question of transmission by telephone after business hours of cable messages to subscribers of the National Telephone Co. in Liverpool, he is of opinion that the best way of meeting the urgent public demand which still exists for their direct delivery by telephone from the offices of the cable companies will be to make an agreement on the subject between the National Telephone Co., the cable companies and himself. Under this agreement authority would be given for the use of the Telephone Company's system in the manner proposed, which otherwise would be an infringement of the conditions of their licence, and the cable companies would undertake to account to the Postmaster-General at the ordinary inland rate for all cable messages delivered or received by them by telephone. The Postmaster General will be glad to know at as early a date as possible whether the National Telephone Co. are willing to enter into an agreement of the kind proposed. If so, he will at once have a draft prepared for the company's consideration. JOHN ARDRON.

West Cumberland.—A scheme for the construction of an electric tramway from Whitehaven to Maryport, through Workington, is being promoted by Messrs. Dick, Kerr & Co.

Will.—The will of the late Mr. B. H. Van Tromp, director of the Brush, County of London and Brush Provincial, Dover Electricity Supply, and Electric and General Investment Co.'s, has been proved, and the gross value of the estate returned at £54,081, personalty being valued at £42,042.

Water Power Utilisation in Bohemia.—The municipal authorities of *Elbogen* (Bohemia) are establishing electricity generating works, and are utilising the water power of the district.

Water Power Utilisation in Spain.—Application has been made by a Bilbao syndicate for a concession to put down plant to utilise the water power of the river Nalon, in Asturias, for the generation of electrical energy.

Willenhall.—The Midland Electric Corporation for Power Distribution start laying their mains here next month, and electric current will be available about February next.

Working Canal Traffic by Electricity.—The success of an arrangement by which canal traffic is worked electrically on the Finow Canal, near Ederswalde, Germany, has led to the consideration of a project for the adoption of a similar system on a portion of the Kaiser Wilhelm Canal at Lübeck. Vessels will be hauled through the canal by electric locomotives running alongside, and when the work of construction is completed this portion of the canal is to be lighted electrically. Messrs. Siemens and Halske carried out the arrangements on the Finow Canal, the experiment being assisted by a grant from the present Government of £1,000.

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers, or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London:—

READY.

(Price 12s. 6d., by post, 13s. 3d.; Colonies, 14s.; abroad, 14s. 6d. (United States, 15s.)

"The Electrician" Electrical Trades' Directory and Handbook for 1900.—In addition to the well-known features of this Directory and Handbook (all of which have been carefully revised and brought quite up to date) a large addition has been made to the Handbook Division, including a Digest of the Law of the Telegraph and Telephone, for the use of municipalities and companies contemplating applying to the Postmaster-General for a Telephone Licence. This section of the book now includes the new model form of Licence issued by the Postmaster-General, the Telegraph Acts and Orders passed by Parliament in 1899, and other information in connection with this the latest development of electrical enterprise. The huge sheet tables of Electric Light and Power and Electric Railway and Tramway undertakings of the United Kingdom have been made quite complete. These sheets form a most complete record of electrical engineering progress in connection with electricity supply and power and traction applications. The Directory Division has been carefully extended and corrected, and is the most reliable list of firms and persons engaged in the electrical and allied industries ever compiled. A number of additional sketches of the careers of well-known electrical experts have been added to the Biographical Division, together with many new portraits. The new volume is the most complete and correct book of its kind ever published in any language.

"The Electrician" Reading Case.—To hold four numbers of the journal. Strongly bound, 1s. net; post free, 1s. 4d.

"Localisation of Faults in Electric Light Mains."—By F. C. Raphael. Price 5s., post free. The book deals with the important subject of localising faults in electric light and power cables; and the various methods of insulation testing are here collected and discussed.

"Wireless Telegraphy: Signalling across Space without Wires by Electric Waves." A Review of the Work of Hertz and his Successors.—By Dr. O. J. Lodge, with a large number of illustrations, bringing this latest application of electrical science quite up to date. New and Enlarged Edition, 5s. nett. *Now ready.*

"The Centenary of the Electric Current, 1799-1899."—By Dr. J. A. Fleming. Price, paper covers, 1s. net, post free 1s. 3d.; strong cloth, s. 6d., post free.

"Motive Power and Gearing for Electrical Machinery."—By E. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free. In this comprehensive work an account is given of the scientific principles and modern practice in the use of engines for dynamo driving, not only for isolated power plants, but also for public electric lighting and power stations. The various forms of gearing in the power station and for electric motors are also dealt with; and the book contains, in addition, numerous tables giving exact data of the equipment and working of electric power stations.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. *New and Cheaper Edition*, 6s., post free.

"The Students' Guide to Submarine Cable Testing."—A new edition of this book, by Messrs. H. K. C. Fisher and J. C. H. Darby, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated.

"Electro-Chemistry."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"The Incandescent Lamp and its Manufacture."—By Gilbert S. Ram. Price 7s. 6d., post free. The principles underlying the manufacture of the incandescent lamp are carefully and fully dealt with in this volume.

"The Manufacture of Carbons for all Electrical Purposes."—by Francis Jehl. 10s. 6d., post free. This is a practical handbook, giving a complete description of the art of making carbons for electric lighting, electrodes, &c., with particulars of the various gas generators and furnaces used in carbonising. The work also contains particulars of the cost, &c. of erecting and working carbon works, and plans of a model factory.

"Magnetic Induction in Iron and other Metals."—By Prof. J. A. Ewing. Price 10s. 6d. net. *New Edition (Third) now ready.*

"Electric Motive Power," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. Price 10s. 6d., post free; abroad, 11s.

"Electrical Testing for Telegraph Engineers."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. Demy 8vo, fully illustrated. 10s. 6d., post free.

"Submarine Cable-Laying and Repairing."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d. This work gives a detailed technical summary of modern practice in manufacturing, laying, testing, and repairing submarine telegraph cables.

"The Alternate Current Transformer."—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. Vol. I.—*New Edition.* Price 12s. 6d., post free, Vol. II., price 12s. 6d., post free, is also ready.

"The Art of Electrolytic Separation of Metals."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free. The author treats fully both the theoretical principles of the art of electrolytic separation of metals and the practical rules and details of technical application on a commercial scale. The work is adapted to the use of the manufacturer as well as the student.

"Electromagnetic Theory."—By Oliver Heaviside. *Vol. I.*, 12s. 6d. *Vol. II.*, 12s. 6d.

"Drum Armatures and Commutators," by Mr. F. Marten Weymouth, also ready. Price 7s. 6d., post free. Prospectus on application. This is a complete treatise on the theory and construction of drum winding, and of commutators for closed coil-armatures, together with a *résumé* of the principal points involved in their design, and an exposition of armature reactions and sparking.

"Electrical Engineering Formulæ," a pocket book, by Messrs. W. Geipel and H. M. Kilgour; price 7s. 6d.; by post, 7s. 9d.; abroad, 8s. *New Edition nearly ready.*

"Bibliography of X-Ray Literature and Research."—A valuable compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of general as well as special information bearing upon the whole subject of electrical discharge research. Edited by C. E. S. Phillips. Price 5s., post free.

"The Manufacture of Electric Light Carbons."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated, price 1s 6d.; post free, 1s. 9d. In this work the author gives useful hints as to the manufacture of electric light carbons, including the preparation of material, firing, saturating, and coring, together with a description and estimate of cost of the plant required.

"Armature Winding of Electric Machines."—By H. F. Parshall and H. M. Hobart. This work has been compiled from notes made by Mr. Parshall in his capacity as Chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables, 30s. post free.

"Temperature Coefficients of 'Conductivity' Copper." Compiled by Messrs. Clark, Forde and Taylor, consulting engineers. Strongly bound in cloth, 2s. 6d. net. Also a Sheet Table of Log. Reciprocals of Coefficients for Copper Resistances at different temperatures from 32°F. to 84·9°F. Printed on strong cardboard, 6d. net.

IN THE PRESS.

"The Electric Arc."—By Mrs. Ayrton.

"Secondary Batteries, their Design and Manufacture."—By E. J. Wade.

"Primary Batteries: Their Construction and Use."—By W. R. Cooper.

"Practical Telephony."—By Dane Sinclair and F. C. Raphael.

"'The Electrician' Wireman's Pocket-book."—Edited by F. C. Raphael. *Nearly ready.*

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office no later than first post Thursday morning. New Catalogues, Price Lists and similar matter should be sent early in the week.*]

TENDERS INVITED.

Whitby District Council invite tenders for the supply and erection of electricity generating plant, some particulars of which are set out in an advertisement. Specification may be obtained at the offices of the consulting engineers (Messrs. Preece and Cardew), 13, Queen Anne's-gate, Westminster. Tenders, addressed to the clerk (Mr. Wm. Seaton Gray), Council's offices, Whitby, must be in before noon of Sept. 3.

Hackney (London) Electric Lighting committee invite tenders for condensing plant, cooling apparatus, pipework and valves, feed pumps, switchboard and boosters, arc lamps, meters, travelling crane, and workshop equipment. Specification, &c., may be obtained at the offices of the consulting engineer (Mr. Robert Hammond), 64, Victoria-street, Westminster, S.W., after 22nd inst., and tenders, addressed to the vestry clerk (Mr. George Grocott), Town Hall, Hackney, must be in by 4 p.m. of Sept. 12. Further particulars are given in an advertisement.

Newcastle-upon-Tyne New Tramways committee invite tenders for conduits and holes for poles. An advertisement contains further particulars, and specifications may be obtained after 17th inst. from the consulting engineer, Mr. Charles Hopkinson (Messrs. Hopkinsons and Talbot), 26, Victoria-street, London, S.W., and 29, Princes-street, Manchester. Tenders (addressed to committee) must be delivered at the office of the town clerk (Mr. Hill Motum) by noon of 31st inst.

The Vestry of St. John, *Hampstead* (London) invite tenders for the supply and erection of (1) eight dry-back marine boilers, (2) steam and water pipes, feed pumps, &c., (3) feed-water heater, or (4) feed-water detartariser, (5) fuel economiser, (6) cast-iron water tank, and (7) two blow-off tanks. Conditions and specifications may be obtained at the offices of the vestry clerk (Mr. Arthur P. Johnson), Vestry Hall, Hampstead, N.W., to whom tenders must be delivered by 4 p.m. of Sept. 27. An advertisement contains further particulars.

Digitized by Google

Oldham Electric Light committee invite tenders for the supply and erection of dry-back marine boilers, with mountings, gangways, feed and drain pipes, &c., complete, and also for mechanical stokers with shaftingand gearing for driving; or water-tube boilers as an alternative to the dry-back marine boilers, including mountings, &c. Further particulars are given in an advertisement, and copies of specifications may be obtained from Mr. A. Andrew, Gas and Water offices, Oldham. Specification and drawings can also be seen at, but not obtained from, the offices of the consulting engineer (Dr. Alex. B. W. Kennedy), 17, Victoria-street, Westminster, S.W., and tenders must be sent to the superintendent (Mr. A. Andrew) on or before Sept. 11.

Hammersmith (London) Vestry require tenders for the supply, delivery and erection of two single-phase alternate-current motors, coupled to two centrifugal pumps, with accessories. Specification may be obtained from the clerk's office, Town Hall, Hammersmith, and tenders must be delivered before 5 p.m., Sept. 12. An advertisement contains further particulars. Mr. F. W. J. Webb is acting clerk.

The managers of the *Poplar* and *Stepney* Sick Asylum District invite tenders for sundry work in connection with a telephonic installation at their sick asylum. An advertisement gives further particulars, and tenders must be delivered to the clerk to the managers (Mr. Robert Foskett), Bromley, Middlesex, E., by 5 p.m., Sept. 17.

Hull Electric Lighting committee invite tenders for steam and water pipes, feed-pumps, water-softener, &c., for their Sculcoates-lane generating station. Specifications may be obtained from the city treasurer, and tenders (addressed to chairman of committee) must be delivered at the town clerk's office, Town Hall, Hull, by noon of Sept. 27. An advertisement contains further particulars.

The Board of Management invite tenders for the electric lighting of the *Preston and County of Lancaster Royal Infirmary*. An advertisement contains further particulars, and specifications, &c., may be obtained at the office of the architect (Mr. F. E. Dixon, C.E.), 19, Lune-street, Preston. Tenders must be delivered to the secretary (Mr. Walter Davies), 5, Winckley-street, Preston, by Sept. 1.

Aberdeen Electric Lighting committee invite tenders for two 200kw. direct-coupled continuous-current generators and one 120kw. balancing set; also for one 420kw. direct-coupled continuous generator. Willans engines are specified in both cases. Further particulars are given in an advertisement, and tenders must be lodged with the city electrical engineer (Mr. J. Alex. Bell), Cotton-street, Aberdeen, by noon on Sept 29.

Tunbridge Wells Corporation invite tenders for the supply and delivery of high and low-tension cables. Specifications from the borough electrical engineer (Mr. Horace Boot), and tenders must be sent to the town clerk (Mr. W. C. Cripps) by 20th Sept. See also advertisement.

Greenock Police Board invite tenders for water-tube boilers, two steam dynamos, boosters, switchboard, steam and exhaust pipes, &c. Further particulars are given in an advertisement, and tenders must be lodged with the town clerk (Mr. C. MacCulloch), Municipal Offices, Greenock, by Sept. 10.

Nelson Corporation invite tenders for a 200kw. steam dynamo. Specifications, &c., may be obtained from the engineer (Mr. A. Allen), Gas Works, Nelson, and tenders must be sent to the town clerk (Mr. R. M. Prescott), Town Hall, Nelson, by Sept. 8. Further particulars are set out in an advertisement.

Southampton Guardians invite tenders for the erection and completion of electrical plant, and an installation for the lighting of the new workhouse infirmary at Shirley Warren. Tenders to clerk (Mr. David P. Gwillim), St. Mary-street, Southampton, by noon, Sept. 11.

Southampton Harbour Board invite tenders for a 30-cwt. portable electric wharf crane. Tenders by Sept 17.

Shipley (Yorks.) District Council invite tenders for steam and exhaust pipes, storage battery, switchboard and connections, and cables. Tenders to clerk by 27th inst.

Cardiff Corporation invite tenders for sundry pipes, feed water heater, &c. Tenders to town clerk, Town Hall, Cardiff, before 31st inst.

Ilford District Council invite offers for "free" wiring in their district. Applications to clerk before noon, 29th inst.

Salford Corporation invite tenders for lighting and traction switchboards, and balancing transformer. Tenders to town clerk by Sept. 3.

London County Council Asylums committee invite tenders for boilers, engines, dynamos, &c, at Horton Estate, Epsom, Surrey. Tenders to committee, 6, Waterloo-place, S.W., by 10 a.m. of Sept. 22.

Stockport Tramways committee invite tenders for 20 double-deck tramcars with electrical equipment. Tenders to clerk by 31st inst.

Portsmouth Corporation invite tenders for plant and apparatus for equipment of tramway power station. Tenders to town clerk by 10 a.m., Sept. 4.

Worthing Corporation invite tenders for electricity generating plant. Tenders to town clerk by noon, Sept. 3.

Luton Town Council require tenders for watt and demand meters. Tenders to town clerk by Sept. 14.

Dorking District Council invite offers for leasing their provisional order. Tenders to clerk by 30th inst.

Middlesbrough Electric Lighting committee invite tenders for wiring the municipal electricity works. Tenders by 31st inst.

Hockheim-am-Main (Germany) Municipal Council invite tenders until Sept. 15 for the erection of electricity supply works. Tenders to der Magistrat.

TENDERS RECEIVED AND ACCEPTED.

The following tenders for generating plant for the proposed new electricity works at the Pigeon House for the Dublin Corporation are recommended for acceptance by the Electric Lighting committee:—

General Electric Co. (compound engines, generators, &c.)	£33,061
Holdsworth & Sons (Lancashire boilers)	6,653
Babcock and Wilcox (water-tube boilers)	5,278
Ditto (fuel economisers)	1,060

Shoreditch (London) Vestry have received the following tenders for electric cables:—

British Insulated Wire Co. (*accepted*)	£1 930 8 2	W. T. Henley's Telegraph Works Co.	£2,147 15 1
Siemens Bros. & Co.	2,262 8 4	W. T. Glover & Co.	2,129 12 6

Cardiff Corporation have accepted the tender of the British Electric Transformer Manufacturing Co. for the supply of ten 30kw. transformers at £690.

Nottingham County Council have accepted the tender of Mr. T. Scott Anderson for the electric lighting of the Radcliffe Asylum. There will be about 1,500 lights.

The tender of the Gateshead Electric and Mechanical Co. has been accepted for the electric lighting of the Ashington Industrial Co-operative Society's premises at New Hirst at £395. Six tenders, varying in amount from £310 to £430, were submitted.

APPOINTMENTS VACANT AND FILLED.

Eccles Corporation invite applications for the position of borough electrical engineer. Further particulars are set out in an advertisement, and applications must be addressed to the Public Lighting and Electricity Supply committee, and delivered at the offices of the town clerk (Mr. Wm. H. Hickson), Town Hall, Eccles, by noon, of Sept. 3.

Two shift engineers are required for the South Shields Corporation electricity works. Applications to borough electrical engineer (Mr. Jos. A. Jeckell) before Sept. 5. See advertisement.

There is a vacancy for an improver at the Dundee electric light and traction station. Applications to city electrical engineer (Mr. Walter H. Tittensor), Dudhope-crescent-road, Dundee, by 29th inst. See advertisement.

Mr. W. H. Eccles, B.Sc., and Mr. C. F. Smith, Wh.Sc., have been appointed senior demonstrator of physics and senior demonstrator of electrical engineering respectively, at the South Western Polytechnic, Chelsea, S.W. Mr. Eccles was educated at the Royal College of Science, where he held a National Scholarship from 1891 to 1897. In 1898 he was appointed senior demonstrator in the physical laboratory of the Royal College of Science. Mr. Smith was educated at the University College, Bristol, and was apprenticed with Messrs. Sharp, Stewart & Co. for four years. In 1894 he obtained a Whitworth scholarship with first-class honours in theoretical and practical electricity. After spending a year in the drawing office and shops of engineering works in Hanover, he was afterwards engaged for six months in Munich in the public experimenting laboratory of the Polytechnic Society. On his return to England he was appointed chief electrical assistant to Dr. Obach at Messrs. Siemens Bros. & Co., and at present is assistant to the managing director of Messrs. Ransomes and Rapier.

Mr. E. Marples, chief assistant to the Liverpool District Lighting Co. (Ltd.), has been appointed electrical engineer to the Hoylake and West Kirby Council, at a salary of £150 per annum.

BUSINESS NOTICES.

Mr. J. H. Blake, Inchbrook, Stroud, and Mr. H. E. Steel, Cheltenham, trading as Blake and Steel, electrical engineers, at Cheltenham and Stroud, have dissolved partnership. Debts by Mr. Steel.

Mr. J. W. Barnard, sole agent for the E.P.S. small storage batteries (Q and V type), 4, Great Winchester-street, E.C., is now "on the telephone," No. 1632 London Wall.

BANKRUPTCIES, LIQUIDATIONS, &c.

A meeting of the creditors of Henry Howe, electrician, 16, Boldlane, Derby, was held last week at the Official Receiver's Office, Derby. The liabilities were stated to be £132 13s. 9d., and the assets 10s. Failure was attributed to illness and losses incurred by a visit to British Columbia. The Official Receiver continues as trustee.

Digitized by Google

Mr. F. J. Saffery, 14, Old Jewry Chambers, London, E.C., has been appointed trustee in the bankruptcy of Claude Vautin (electro-metallurgist), in place of the late trustee, Mr. J. J. Saffery, deceased.

In the bankruptcy of W. V. Scott, electrical engineer, lately residing at Shaftesbury-road, East Hammersmith, the first meeting of creditors will be held on Aug. 30, and the public examination on Oct. 16, both at Bankruptcy Buildings, London, W.C.

Claims against Herbert Sewell, electrician, &c., Clifton-place, and 63, Birklands-road, Shipley, must be in by Sept. 5. Mr. J. A. Binns, official receiver, 31, Manor-row, Bradford, is trustee.

The discharge in bankruptcy of F. G. W. J. Adams, lately trading with C. M. Downie as Downie and Adams, electrical engineers, at 24, Newman-street, London, W., has been suspended for two years.

A receiving order was made at the Burnley County Court on Tuesday against Robert Foster & Co., electrical engineers, Adlinton-street, Burnley, also trading as the Nelson Electrical Engineering Co, Stott-street, Nelson (Lancs.).

On Wednesday the creditors and shareholders of the Willoughby Destructor Syndicate (Ltd.), met at the Board of Trade offices, London, under a winding-up order. The company was formed in August, 1898, with a nominal capital of £3,200, in 1s. shares, to exploit patents and inventions relating to destructor furnaces for town refuse, and acquired several patents for a consideration of 63,993 fully-paid shares in the syndicate. A destructor was erected for the Devonport Corporation, but was refused, and this event and the differences among the directors led to the winding-up order. The liquidation is in the hands of the Official Receiver.

It has been resolved to wind up the British Blahnik Arc Light Co. (Ltd.) voluntarily. Mr. W. H. Chantrey, 57, Moorgate-street, E.C., is liquidator.

Sale by Auction.—Catalogues are now ready giving particulars of over 500 lots of high-class new engineering plant and machinery, electro-plating plant, loose tools and utensils, stores, &c., which will be sold by auction by Messrs. Wheatley Kirk, Price & Co. on Tuesday and Wednesday next, Aug. 28 and 29, at 10 for 11 o'clock prompt each day, at the Ormonde Works, Hornchurch-road, Romford, Essex. Illustrations are given of some of the more important machine tools included in this sale, and special attention is called to the quantity of practically new machine tools of a light character which are included in the auction. The extensive works premises are also to be disposed of. An advertisement gives further particulars.

Tramway Undertaking for Sale.—The liquidator of the Isle of Man Tramways and Electric Power Co. (Ltd.) (Mr. W. H. Walker, C.A.), 42, Castle-street, Liverpool, and 50, Athol-street, Douglas, announces in an advertisement that it is intended shortly to offer for sale by tender the electric, cable, and horse tramway undertaking of the company, together with the plant, cars, &c. Full particulars can be obtained from the liquidator.

English-Made Electric Bells, &c.—We have received from Messrs. Julius Sax & Co. (Ltd.). of Eagle Works, Coldharbour-lane, Camberwell, London, a copy of a new catalogue dealing with electric bell material, guaranteed (where described as of "best English make") to be of English manufacture, and known in the trade by the "Eagle" trade mark. Messrs. Julius Sax & Co. point out that the firm has been in existence since 1855, and claim that this catalogue is the most complete list relating to electric bells and electric bell material ever issued. Certainly great care has been taken in the compilation of the list, and a word of praise is due to the general excellence of the illustrations. The list occupies nearly 120 large quarto pages, and covers a wide range of this branch of electrical work. The trade only is catered for, and the discounts are on a very liberal scale.

B.T.H. Plant.—Pamphlet No. 73, issued by the British Thomson-Houston Co., illustrates and describes direct-current enclosed arc lamps.

English-Made Specialist Watches.—Messrs. S. Smith & Son, of 9, Strand, London, W.C., have on view at the Paris Exhibition a fine display of London-made watches, chronometers, &c., and in connection with this exhibit issue a pamphlet in French and English containing some interesting particulars and illustrations of a large number of watches with special movements. Some idea of the requirements of the scientific watch trade is given in the descriptions accompanying the illustrations, the watches specially described ranging in price from £450 to £50. The firm of S. Smith & Son was established 70 years ago and has continued in the fronk rank, as is evidenced by its extensive trade in watches and watch movements of the most intricate character, which are regulated up to a variation of 1sec. per month. In 1884 the British Government established a system of official certification in English watch-making for merit alone, and in that year Messrs. S. Smith & Son gained the first position and still hold it in 1900 with a watch which has secured the record with a total of 88·7 points out of a possible 100 at the Government Observatory at Kew. One watch exhibited at Paris (price £500) is 2in. in diameter, ½in. in thickness, and has combined movements of a perpetual calendar, showing the day of the week, day of the month, month of the year, and the year itself, including leap year; the changing phases of the moon, the fifths of seconds and the minutes of a split-seconds chronograph, a repeat action striking the minutes, quarters, and hours, besides the usual time dial of the ordinary watch. The revolving escapement, the latest important improvement in watchmaking, is brought into use for the first time in these fine examples of the watchmakers' craft. Hundreds of Messrs. S. Smith and Son's non-magnetisable watches are in use in the electrical profession throughout the world, and we can testify that in all cases which have come under our notice great value is set upon these time recorders by their owners. The Paris exhibit includes an infinite variety of watches and clocks, some of the latter being shown in exquisite examples of English-made clock cases of choice design. Messrs. S. Smith & Son have been awarded a bronze medal for their exhibit at Paris.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Aug. 15 to Aug. 21, with the ports of destination:—

Africa—Alexandria, £428 (including £207 telegraph wire); Cape Town, £798 (including £150 telegraph apparatus); Durban, £1,019; East London, £232. *Argentina*—Buenos Ayres, £607 (telegraph material). *Australasia*—Brisbane, £125; Rockhampton, £54; Sydney, £1,989 (including £210 telegraph material); Wellington, £30. *Belgium*—Ostend, £300. *Ceylon*—Colombo, £140. *China*—Foochow, £18. *France*—Boulogne, £24. *Germany*—Hamburg, £180 (telegraph material). *Holland*—Rotterdam, £115 (telegraph wire). *Hong Kong*—£29. *India*—Bombay, £86; Calcutta, £650. *Sweden*—Stockholm, £38 (telegraph wire). Total £6,862, against £11,651 for six days last year (Aug. 16 to Aug. 21).

PATENT RECORD.

The following list of Applications for Patents and Specifications published has been compiled for this journal by Messrs. J. C. Chapman and Co., *Chartered Patent Agents, of 70, Chancery-lane, W.C., from whom any available information in connection with Patents, Designs, and Trade Marks may be obtained.*

APPLICATIONS FOR PATENTS.

Note.—*The undermentioned Applications are not open to public inspection until after the acceptance of the complete Specification. The names within parentheses are those of communicators of inventions. When complete specification accompanies application, an asterisk is affixed.*

June 12, 1900.

10,679. A. Reame and C. Wokes. London. Improvements in or connected with fuse boards for the distribution of electricity.

10,688. L. de L. Wells and A. C. Brown. London. Improvements in electric telephones and apparatus relating thereto.*

10,703. V. Thomas. London. Improvements in the manufacture of filaments for electric incandescence lamps.

10,711. A. De Filippi. London. Improvements in and relating to electric signalling apparatus for railways and the like*

10,713. P. Imhoff and The United Alkali Co. (Ltd.). London. Improvements in means to be employed in the electrolytic manufacture of bleaching liquors and chlorates.

10,724. W. P. Thompson. Liverpool. Improvements in electric current interrupters. (The Voltohm Elektrizitäts-Gesellschaft, A. G., Germany.)

June 13, 1900.

10,743. C. W. Hill. London. Improvements in dynamos and motors.

10,751. W. H. Willatt. Hull. Improvements in electrical generators and electrical motors.

10,755. W. H. Willatt. Hull. Improvement in the governing by electricity of steam engines and other prime movers.

10,772. A. Reame and C. Wokes. London. An improvement in or connected with laminated electric switches.

June 14, 1900.

10,808. H. A. Couchman. London. Improvements relating to electric arc lamps.

10,811. C. A. Henderson. Edinburgh. An improved self-acting time switch or cutout for electric arc lamps.

10,833. R. Fabry. London. Improvements in and relating to electric accumulators.

June 15, 1900.

10,890. A. Hudson. Bolton. A life-saving guard or fender for electric tram cars or other motor vehicle which works automatically, or can be worked by the driver with a foot press or hand lever.

10,892. S. Jevons. Birmingham. Improvements in metal conduits or covers for enclosing the wires or cables used for the transmission of an electrical current.

10,913. H. H. Lake. London. Improvements in and relating to stop-mechanism for phonographs and the like. (T. S. Parvin, United States.)*

Digitized by Google

June 16, 1900.

10,940. J. SWINBURNE. London. Improvements connected with electrolytic incandescent electric lamps.
10,970. P. M. JUSTICE. London. Improvements in electric telegraphs. (The Rowland Telegraphic Co., United States.)
10,974. A. RICKS. Liverpool. Improvements in electric accumulators, electrodes, or plates.*
10,985. J. WILKINSON and J. H. NOAD. London. Improvements in the production of soda and hydrochloric acid by electrolysis.
11,003. H. H. LAKE. London. Improvements in electric railways. (McElroy-Gruno Electric Railway System, United States.)*
11,006. H. H. LAKE. London. Improvements in secondary electric batteries. (Aroid Renterdahl, United States.)*

June 18, 1900.

11,011. H. W. CLOTHIER. Sheffield. Improvement in electrical switches for heavy currents and high potentials.
11,020. W. M. WALTERS. Liverpool. Improvements in or connected with electric lamps.
11,022. J. E. MACAULAY. Dublin. An electrical apparatus for adjusting tram-rail points.*
11,025. H. BINKS. London. Improvements in electric apparatus for life-buoys, and light to facilitate the rescue of persons from drowning and for other purposes.
11,026. A. P. LUNDBERG and G. C. LUNDBERG. London. Improvements in cord grips for electric light fittings.*
11,054. N. GARLAND. London. Electrically-operated cloth cutting machines.

June 19, 1900.

11,097. H. WOODWARD. Birmingham, Improvements in electrical accumulators or secondary batteries, and in the manufacture of the same.
11,099. J. PATERSON. London. Improvements in electric targets.*
11,107. E. EDWARDS. London. Improvements in electric patterns for punching machines, for embroidering machines, and for jacquard looms. (Curt Handwerck, Germany.)*
11,120. J. B. GOTTSBERGER. London. Improvement in plows for conduit electric railway cars. (Date applied for under Patents, &c., Act, 1883, sec. 103, Jan. 4, 1900, being date of application in United States.)*

June 20, 1900.

11,149. A. WHALLEY. Warrington. Improvements in telephone switch-boards.
11,190. SIEMEN BROS. & CO. (LTD.). London. An improvement in switches for high-tension electrical currents. (Siemens and Halske, Aktien Gesellschaft, Germany.)*
11,206. G. W. PARTRIDGE and G. K. B. ELPHINSTONE. London. Improvements in electric switches and like apparatus for making and breaking electric circuits.
11,207. L. ANDREWS. London. Improvements in or relating to the distribution of electricity.
11,208. F. J. WARDEN-STEVENS. London. Improvements in electric signalling apparatus.
11,217. G. E. HEYL-DIA. Liverpool. Improvements in the method of and material for covering electric cables, conductors, or wires with insulating material.

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1899.

7,370. LEIGH (Sprague). Control of electrically propelled vehicles and trains.
8,188. MARR, LAIDLER, and SUNDERLAND FORGE AND ENGINEERING CO. (LTD.). Rheostats or electric resistance switches.
12,279. EVERSHED AND VIGNOLES (Ltd.) and EVERSHED. Electric telegraphs for ships and other purposes.
12,565. ABEL (Karmin). Windings of dynamo machines and induction motors.
12,730. OFFENBROICH and ROCKEL. Galvanic cell.
12,767. BEAUMONT. Coin-freed electricity meters.
12,883. DUMONT. Apparatus for repairing incandescence electric lamps. (Date applied for under International Convention, April 12, 1899.)
12,962. NORTHEY and ELECTRIC MOTIVE POWER CO. (LTD.). Electrically-propelled road vehicles.
13,018. BARTON and GORHAM. Electric arc lamps.
13,053. SANDERS. Anti-vibrating springs for incandescent and other lamps.
13,054. SANDERS. Holders for globes and shades of gas, electric and other lamps.
13,111. WADE and ELECTRIC MOTIVE POWER CO. (LTD.). Electrical switches.
13,174. HERZOG. Electric signalling apparatus.
13,271. SINCLAIR and AITKEN. Telephone exchange systems.
13,509. ALDRIDGE. Electric cranes.
13,616. EVERSHED and VIGNOLES (LTD.) and EVERSHED. Motor electric meters, parts of which are applicable to motors and dynamos generally.
13,617. RIMINGTON. Electrical Measuring instruments.
13,646. HOLLICK. Electrical motive power apparatus.
13,846. CORDNER. Manufacture of a composition from rhea fibre applicable for electric insulation and other purposes.
13,994. VERITYS LIMITED and RIDINGS. Key switch for electrical circuits, particularly adapted for incandescent lamp sockets.
13,995. VERITYS LIMITED and RIDINGS. Carbon-feeding mechanism of electric arc lamps.

1900.

507. CLARKE. Construction and manufacture of electric bells.
839. LAKE (Shearman). Incandescence electric lamps.
1,445. LORING and CLARK. Electric transformers. (Date applied for under International Convention, June 24, 1899).
2,119. WATERHOUSE and SIMPLEX STEEL CONDUIT CO. (LTD.). Junction boxes for electric conductors.
2,964. HOWARD. Manufacture of pipes or conduits for electrical conductors, or for conveying liquids or gases or for analogous purposes.
3,527. HANSEN. Adjustable contact for electric alarm clocks.
4,109. GOLBY (Hansen). Electric clock.
4,785. DÉRI. Alternating-current motor.
5,178. DAY (White). Means for connecting electric cables.
5,486. QUINTAINE. Process for depositing pure tin by electrolysis.
6,185. HEYS (Scott, Varley and Anderson). Apparatus for winding wire and other material into coils and the like for electrical and other purposes.
6,188. BOUTILLIER and HUNTER. Armoured conduits for electric wires.
6,296. BORCHERS. Electric furnaces.
6,308. FESSENDEN. Electric incandescent lamps.
6,355. COOLEY. Methods of and apparatus for electrically separating the relatively volatile liquid component from the component of relatively fixed substances of composite fluids.
6,478. JONES. Electromagnetic mechanisms for producing reciprocating motion.
6,483. SIEMENS BROS. & CO. (LTD.). Siemens and Halske Aktien Gesellschaft. Apparatus for simultaneously actuating from one point the controlling switches of the several electrical motor cars of a train.
6,526. MÜNKER. Electric fire alarms.
6,684. DERVIN. Electric coherers.
6,878. JAMES. Electric arc lamps.
6,951. STEELE. Instrument for measuring electric currents.
7,084. BOULT (Pieper and Pieper). Electric motors.
7,098. SHORT. Multipolar electric machines.
7,100. HOLLUB and MIGNAL. Device for fixing incandescence electric lamps.
7,108. SIMMS and BOSCH. Magneto-electric machines.
7,109. VARLEY. Electro-magnetic coils.
7,198. THOMPSON (Sinding-Larsen). Method of producing complex chemical compounds by electrolysis with alternating currents.
7,410. KÄSBAUER, HABERFELLNER and LENCK. Regulators for electric arc lamps.
7,482. TIMAR. Electric sweating mattress.
7,562. BRITISH THOMSON-HOUSTON CO. (LTD.) (Rice). Third rail insulators for electric railways.

NEW COMPANIES, STATUTORY RETURNS, &c.

BRITISH MOTOR TRACTION CO. (LTD.)—This company was recently registered, with a capital of £1,000,000 in £1 shares, to adopt various agreements and to carry on the businesses of manufacturers of and dealers in motors, cycles, vehicles, &c., electricians, mechanical engineers, &c.

DONOVAN AND CO. (LTD.)—This company was registered on Aug. 15, with a capital of £10,000 in £1 shares, to acquire from Mr. E. W. Donovan the business carried on by the Electroid Gas Light Syndicate (Ltd.), and by J. S. Leach & Co. (Ltd.), and to carry on the business of mechanical, electrical, and hydraulic engineers, boiler makers, &c. The first directors are C. Pilkington (chairman), and E. W. Donovan.

MORDEY-FRICKER ELECTRICITY CO. (LTD.)—This company was registered on Aug. 13, with a capital of £20,000 in £1 shares, to acquire the benefit of certain inventions of Mr. W. M. Mordey and Mr. Guy C. Fricker, and to carry on the business of electricians, manufacturers of electricity meters, &c. The subscribers (with one share each) are J. Atherton, J. B. Atherton, W. M. M. Forwood, H. J. Russell, W. M. Mordey (electrical engineer), Guy C. Fricker (electrical engineer), and A. W. Haptie. The first directors are Jacob Atherton, George H. Nisbett, and Guy C. Fricker.

ROGERS & GOWLETT (LTD.)—This company was registered on Aug. 16, with a capital of £10,000 in £1 shares, to acquire the business carried on by Rogers Bros., at Watford, and to carry on the business of electricians, ironmongers, &c. The first directors are J. Rogers and P. Gowlett.

TURNER, ATHERTON & CO. (LTD.)—This company was registered on Aug. 8, with a capital of £175,000 in £1 shares, to acquire the businesses carried on by John Turner & Sons, John Turner, the Turner Machine Co., Turner Bros., and Giles Atherton, and to carry on the business of electrical and general engineers, cycle and motor car manufacturers, &c. Messrs. H. H., Albert, and Arnold Turner and G. Atherton are permanent governing directors, and Messrs. W. H. Atherton and W. E. Turner are managing directors.

BRITISH ALUMINIUM CO. (LTD.)—The annual return to June 7 has been filed. The capital is £400,000, in 20,000 7 per cent. preference, 10,000 ordinary, and 10,000 "A" 6 per cent. preference shares of £10 cash, of which 20,000 7 per cent. preference and 10,000 ordinary have been taken up. £10 per share has been called up on 16,770 7 per cent. preference and eight ordinary shares, and £167,780 has been received. £132,220 is considered as paid on 13,222 7 per cent. preference and ordinary shares.

Digitized by Google

CALLENDER'S CABLE AND CONSTRUCTION CO. (LTD.)—The annual return to June 7 gives the capital as £400,000, in 40,000 ordinary and 40,000 preference shares of £5 each, of which 30,000 ordinary and 33,420 preference have been taken up. £5 per share has been called up on 10,000 ordinary and 33,420 preference shares.

ELECTRICAL POWER STORAGE CO. (LTD.)—The annual return to July 26 has been filed. The capital is £100,500, in 100 founders' and 20,000 ordinary shares of £5 each, of which 66 founders' and 18,592 ordinary have been taken up. £5 per share has been called up on 66 founders' and £4 per share on 3,132 ordinary shares.

THOMAS PARKER (LTD.)—According to the annual return to July 13 the capital is £75,000, in £10 shares, all of which have been taken up. £10 has been called up and paid on 5,750 shares, and £17,500 is considered as paid on the remaining 1,750.

NOTES.

THE Dublin Corporation is fully bent on having its own municipal electric light works. It will be remembered that the rival scheme of the Dublin Electric Lighting Syndicate, which fought its way through the House of Commons Committee stage, was thrown out on the motion for the third reading owing to the vigorous opposition of the supporters of the Corporation scheme. On Monday last, at a meeting of the Corporation, this municipal authority was given one last chance of avoiding the mistake of erecting a costly lighting station three miles from a city which already possesses an electric tramway power station capable of supplying all the current required for electric lighting. The Dublin United Tramways Co., the owners of that power station, made an offer at this meeting to sell to the Corporation all the current required for public and private lighting and electric supply; but after a long and heated discussion the proposal was rejected by 38 votes to 14, the Corporation deciding to proceed immediately with its own scheme. Indeed, tenders for contracts for machinery to the value of £46,000 were on that day accepted. In view of the fact that the extensive system of electric tramways now being built up in and around Dublin, with its central and admirably equipped power station, will, at some future date, be liable to compulsory purchase by the Corporation on the modest, if not exactly reasonable, terms of the Tramways Act, we regard it as decidedly short-sighted for the Dublin Corporation to erect a separate power station at the Pigeon House Fort. However well this may serve as a temporary expedient until the time of purchase arrives, and perhaps as a political move at the present moment, we cannot but regard it as a measure which conflicts with the future and lasting interests of the capital of the sister island.

WE invite the attention of our readers to a letter we publish this week, in which Mr. H. E. MAVOR discusses the relation of the improved value of land to the success of any electric power scheme. It will be remembered that in our last issue we commented upon a letter from Mr. MAVOR which appeared recently in the *Glasgow Herald*. The letter in our columns to-day is a clearer and more explicit statement of his main position. He avows that his object is "to direct attention as strongly as possible to the importance of the element of increment in value of land to promoters of power transmission schemes." Incidentally the question is stated to be one of importance to electrical manufacturers, because if a power scheme is successful it will bring grist to their mill. Mr. MAVOR illustrates his main proposition by a "concrete example on a small scale," and one under his own personal observation. Factory buildings adjoining the place where his company's engineering works have been erected have been so greatly improved in value by being supplied with cheap electric power, that, though they formerly did not let, now the rents bring in a handsome profit to the company; but the company is supplying current at a rate which, taken by itself, would not be remunerative.

SUCH is the illustration; and we may believe that Mr. MAVOR would have us apply it, on a suitably magnified scale, to the large electric power schemes which are now so prominently before electrical engineers and the industrial world. In other words, to secure success an electric power scheme must not be an electric power scheme *pur et simple*, it must necessarily also be a commercial land development scheme. Simple power schemes cannot be expected to succeed; combined with the business of purchasing and letting land and factory buildings they may prove sufficiently remunerative to justify their existence. This we take to be Mr. MAVOR's proposition; and, if we mistake him not, we unhesitatingly assert that, so far at any rate as concerns the industrial districts of England, he is wrong.

Digitized by Google

Mr. Mavor directs attention to Niagara—the most glorious instance of a successful combination of electric supply and commercial land development. Granted; but Niagara is not England. The conditions which prevail there are totally different from those to be found in our own industrial counties. Other conditions, besides cheap power and land, combined to create the industrial town of Niagara Falls. Cheap land would have been still cheap land, and as wild a waste as ever, had there not existed ready to hand cheap inlets for raw materials and cheap outlets for finished products—the water-way and the railway. But in England the cheaper and more ready inlets and outlets have already been utilised, and industrial cities and towns have sprung up at the places where they occur. Steam has done already there what electric power has done at Niagara, and what Mr. Mavor expects electric power still to do in this country. Here the pick of the land has already been developed and is now teeming with industries. The electric power undertaking that will bring really cheap power to the doors of the existing factories will reap a far better harvest from the already tilled field than will the combined electricity and land development scheme that goes out prospecting in regions hitherto despised by the industrial manufacturers.

But though we cannot concede that land development is a *sine quâ non* in electric power schemes, we are quite prepared to admit that throughout the country there are hundreds, perhaps thousands, of acres of idle land that would be substantially improved in value through being converted by electric power from the industrially unsuitable to the industrially suitable. It may be questioned even here, however, whether it would be advisable for the electric power company to risk the annexation of such property, or whether it would not be better to leave this class of speculation to individual landlords. Mr. Mavor's concrete example may be safe to imitate on a correspondingly small scale; but it is extremely doubtful whether it would be to the advantage either of the electrical or of the general industrial world for electric power undertakings covering half a county or more to be mixed up with land speculation. Besides, there is the politico-economic aspect of the question, which, however far afield its consideration may lead us from electrical matters, is not less significant in its warning against the alliance Mr. Mavor advocates. Shall the great financial corporations that are to supply us, by the county-full, with light and power, who are to operate and control our tramways and electric railways that carry us and our industrial goods, be also our landlords? It is a condition fraught with much danger.

Some time ago a dispute arose between Messrs. Brown, Boveri & Co. and the local authorities controlling the Stansstad-Engelberg and Zermatt-Görnergratt three-phase electric railways with regard to the pressure at which these lines should be worked. The contractors proposed 750 volts, but the authorities refused to allow more than 500 volts owing to the alleged danger. Accordingly the contractors engaged Prof. H. F. Weber, of Zurich, to report as to the danger of pressures exceeding 500 volts, and to this end Prof. Weber conducted a series of experiments on the physiological action of electric pressures on the human body, using his own *corpus vile* for the purpose—not without considerable risk. A description of the experiments undertaken, and results obtained, will be found in an article by Mr. William Rung, of the firm of Brown, Boveri & Co., in our Danish contemporary the *Civilengeener*.

Two classes of experiments were made with a view to settle, firstly, the risk when both hands simultaneously touch both bare leads, or when both leads come in contact with a bare part of the body; and, secondly, the risk when a person standing on the railway or on a car touches one or other of the leads. Prof. Weber investigated the first case by using an iron ring wound with 680 turns of wire carrying an alternating current at a frequency of 50 ∿. The voltage between the first and last turns was 210 volts, and connecting wires were soldered to each successive thirtieth turn, thus giving intermediate voltages, to which Prof. Weber subjected himself in ascending scale.

With wet hands the limiting safe pressure appeared to be 50 volts, this pressure causing instantaneous paralysis of all the muscles of the fingers, hands, and arms. With dry hands as high as 90 volts could be taken, though this pressure produced instantaneous paralysis of the hands. From these experiments Prof. Weber infers that all pressures exceeding 100 volts are dangerous when contact is made with both poles of an alternating-current circuit; and, since this pressure produces muscular fixation, there is a decided risk of fatal consequences, the victim being unable to release himself. In the second class of experiment Prof. Weber, standing on moist gravel soil, subjected himself to gradually ascending pressures by touching intermediate points in a series of 20 glow-lamps, each taking 100 volts, and all well insulated. When the live conductor was slightly touched a pressure of 1,000 volts produced a stinging resembling a burn by a flame, but when the live conductor was firmly gripped a pressure of only 700 volts produced intense trembling of the fingers, hands, arms, and ankle joints. It was therefore inferred that to touch a single pole is not dangerous if the pressure does not exceed 1,000 volts. These experiments, it appears, were regarded as sufficient justification for running the two railways at 750 volts.

Although we cannot but admire the pluck which Prof. Weber displayed in seeking to discover by his own body the danger limit of alternating electric pressure, we fear that his experiments are far from conclusive. In the first place it is now fairly well established that pressures which to some individuals are highly dangerous, if not fatal, can be taken with impunity by others under precisely similar conditions. But Prof. Weber's experiments are open to more searching criticism than this, for there is no evidence that they were conducted under conditions at all resembling those met with in practice in traction and overhead electric lighting circuits. To investigate the mere pressure which the human body can stand is not sufficient. We ourselves

Digitized by Google

have frequently been subjected to several millions of volts with impunity. The shock from a small Leyden jar, though produced by millions of volts, is quite harmless. Regard must therefore be paid, not merely to the pressure, but to the amount of horse-power at the back of it, as well as to the inductance and electrostatic capacity of the circuit from which the discharge is taken. In the first series of experiments the danger limit would probably have been considerably lowered if, instead of a small choking coil, carrying a comparatively weak current, the circuit of a large alternator of several hundred horse-power had been employed. In the second series of experiments, the risk would certainly have been enhanced and the danger limit would have been lowered by the introduction of a considerable electrostatic capacity or electromagnetic inductance into the circuit touched by one hand, for in either case, though the pressure might have been the same, the impulsive discharge through the body to earth would surely have been attended by greater danger. We regard it, therefore, as being by no means proven that all pressures between 100 and 1,000 volts are equally safe, and until the matter has been investigated under circumstances more resembling those in actual practice, it would be unwise to act on the incomplete evidence afforded by Prof WEBER'S experiments.

A CURIOUS phenomenon has occasionally been observed in the glow lamps on the circuits of the Calcutta Electric Supply Co. at times when Calcutta has been visited by exceptionally severe thunderstorms. Immediately following each lightning flash the brightness of the glowing lamps has been observed to increase suddenly, gradually returning to the normal incandescence. This phenomenon has so frequently been observed, that the engineers of the company have sought every possible explanation of the curious phenomenon, but have been unable to find any defect in their circuits—which are on the overhead wire system—that might offer an explanation. Indeed the only conceivable explanation is one which appears so extraordinary that many may find considerable difficulty in accepting it. It is well known that carbon, acting as a coherer in a wireless telegraph apparatus, undergoes the usual sudden decrease in resistance when subjected to electric radiation. It is possible that the carbon filaments of a glowing lamp may undergo a similar change when exposed to the influence of a tropical thunderstorm in its immediate vicinity. This sudden decrease in the resistance of the filament would, of course, produce a correspondingly rapid increase in its candle-power, after which the gradual self-decoherence of the carbon would account for the return of the lamp to its normal incandescence. We are not aware that this remarkable effect has been detected in any other electric supply circuit, but should this have been the case it might further elucidate the phenomenon if the engineers who have observed it would now make the facts public.

Wusung-Chefoo Cable.—The Eastern Telegraph Co.'s new cable steamer "John Pender" left Shanghai on Tuesday to lay a cable between Wusung and Chefoo (China).

Electric Luggage Cranes at Dover Pier.—It is intended shortly to erect electric cranes on the Admiralty Pier at Dover for the purpose of handling the passenger luggage and mails between the trains and steamers.

Opening of the Rathmines Municipal Electric Supply Works.—The official opening of these works by their Excellencies the Lord-Lieutenant of Ireland and the Countess Cadogan is announced to take place this afternoon.

The British Association.—Among the attractions at the British Association meeting at Bradford next week is to be an exhibition of wireless telegraphing between a captive balloon and the ground. This exhibition will be conducted by Mr. J. M. Bacon and Messrs. Maskelyne of the Egyptian Hall.

Cable Interruptions:—	Date of Interruption.
Latakia—Cyprus	June 21, 1899
Cayenne—Pinhieros	Oct. 11, 1899
Tangier—Tarifa	Jan. 3, 1900
Ceara—Maranham	Feb. 20, 1900
Pará—Maranham	Mar. 2, 1900
Môle-St. Nicolas—Cap Haitien	Mar. 7, 1900

Alternate Current Drop and the Westinghouse Compensator.—We have received from the Westinghouse Electric and Manufacturing Co. a pamphlet embodying a reprint of a Paper by R. D. Mershon on "Drop in Alternate Current Lines," which appeared in the *American Electrician* in 1897, together with a description of the Westinghouse compensator, an instrument based on the principles set forth in this article, for the purpose of indicating at the power station without the use of pressure wires the voltage at the feeding point under any condition of drop in the feeders. The pamphlet is illustrated and gives technical particulars of the instrument.

Wireless Telegraphy in the Navy.—Orders have been issued by the Admiralty for the equipment with wireless telegraph apparatus of 18 of Her Majesty's battleships and for shore stations at Malta and Gibraltar. The battleships include the "Alexandra," "Powerful," "St. George," "Gibraltar," "Brilliant," "Gladiator," and "Juno"; also four ships on the Mediterranean station—viz., the "Ramillies," "Andromeda," "Theseus," and "Venus," and two ships at Hong Kong. The Admiralty have also ordered estimates from the Portsmouth Dockyard for fitting wireless telegraph apparatus to shore stations at Dover, Culver Cliff, Rames Head, Scilly and Roche Point.

Atlantic Cable Extensions.—The Telegraph Construction and Maintenance Co.'s cable steamer "Anglia" on Tuesday last completed the laying of the cable for the Deutsch Atlantische Telegraphen Gesellschaft from New York to Fayal, Azores. It is a coincidence that the communication was completed on the fiftieth anniversary of the laying of the first sub-marine cable—that between France and England on 28th August, 1850. This cable establishes direct communication with Emden, Germany, and is the second line from Fayal to North America, the Commercial Cable Co.'s line working from Canso (Nova Scotia) to Fayal.

Thunderstorms.—Considerable damage has been done by lightning during the past week. At Inverness Post Office lightning set fire to the instruments, apparently through the failure of the lightning guards. The damage, however, was slight. During a violent storm at Stevenston, in Scotland, lightning caused an explosion at Messrs. Nobel's dynamite and gun-cotton factory. It appears that the lightning struck two gun-cotton drying stores; two men were injured, but not fatally. At Clapham, the Board School in Wandsworth-road was struck by lightning, a portion of the masonry being detached and falling into the roadway. Damage also resulted from storms at Durham, Felling, Gateshead, and other places in the North of England.

The "Demon" Water Motor.—A new pattern of impulse turbine or water motor on the Sellon wheel principle has recently been put on the market by Mr. P. Pitman, of Halifax. The revolving wheel is contained within a wheel-case, there being somewhat less than the usual amount of clearance between the vanes and the inside of the case. Instead of the water from the jet being received by the vanes and thrown out radially the vanes are bifurcated so as to throw the water out sideways, the water being thus discharged clear of that part of the wheel-case in which the wheel revolves. It is claimed that with this construction a minimum of friction is obtained between the water and the wheel, and that a high efficiency is the result.

GUERNSEY ELECTRIC SUPPLY WORKS.

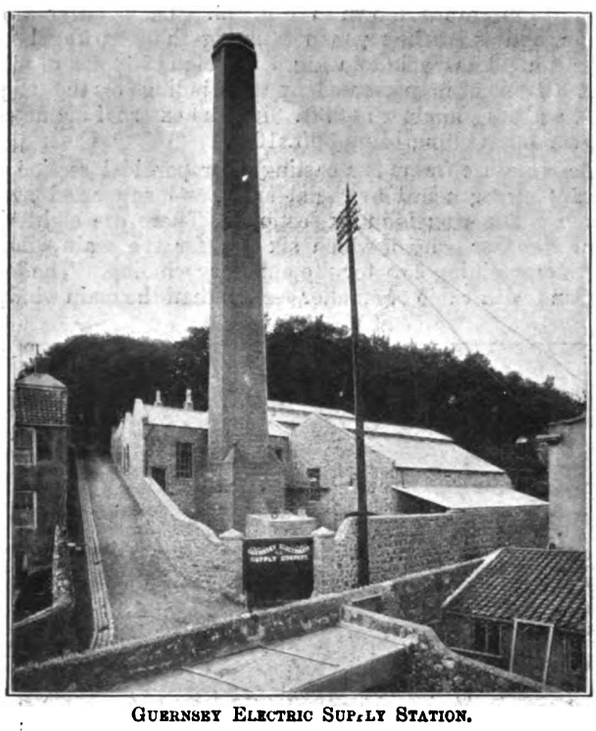
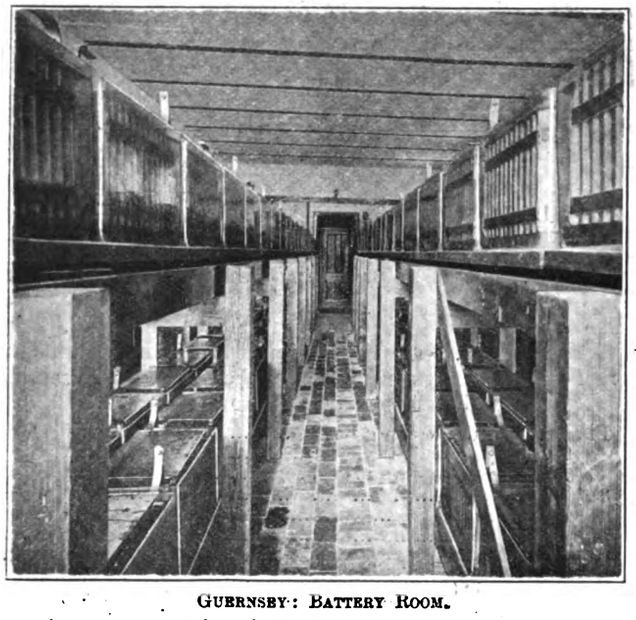
On July 25th last the opening took place of the electric supply works erected by Edmundson's Electricity Corporation at Les Amballes, a suburb of St. Peter Port, in the island of Guernsey. These works have been erected for the supply of electricity for lighting and power in St. Peter



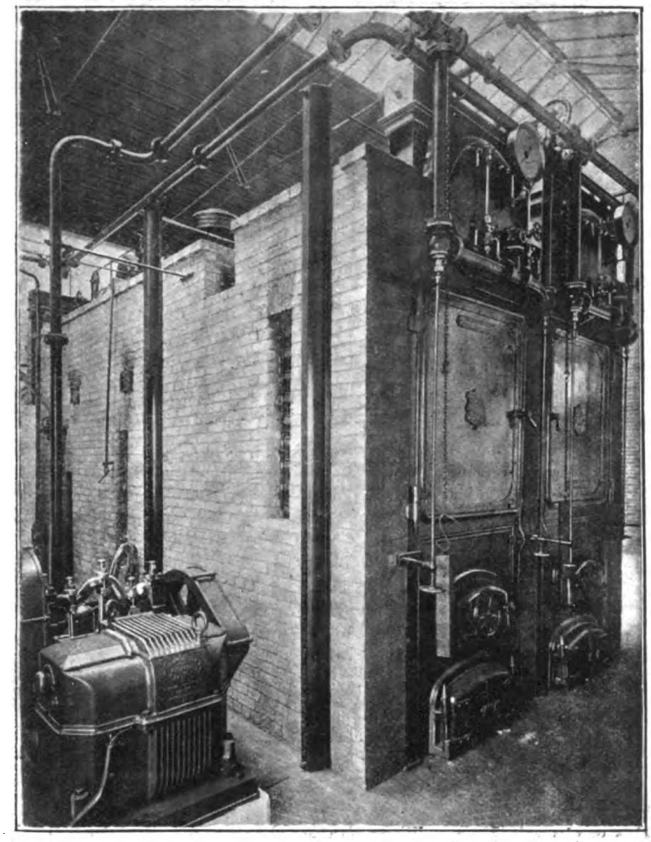
GUERNSEY ELECTRIC SUPPLY STATION.

Port, the principal town in the island. The accompanying map indicates the area at present supplied with current, and our other illustrations are from photographs of the power station and its various departments. We may mention that the entire capital for this undertaking has been found by Edmundson's Corporation, no subscriptions having been invited as yet from the outside public.



GUERNSEY: BATTERY ROOM.

The present capacity of the works is 2,000 8 c.p. lamps, but extensions are in hand which will largely increase this capacity. In the machinery room, that is to say, space has been left for two additional generating sets, each capable of supplying 5,000 lamps, and one of these is to be erected almost immediately. The boiler-house is equipped at present with two Babcock and Wilcox boilers, each having 1,218 sq. ft. of heating surface, and generating steam at 160lb. pressure. Steam is superheated by means of a Babcock and Wilcox superheater. The feed pumps include a Worthington steam feed pump with a capacity of 10,000lb. per hour and a Hayward-Tyler three-throw electric pump having a capacity of 13,000lb. The steam pipe range consists of a ring main of wrought steel with welded seams. The feed pipes are arranged in duplicate, allowing either pump to supply either of the boilers, and there is a by-pass allowing of either cold or hot feed. The feed water is heated by means of a Green's economiser having 96 tubes. Within the machinery room there are at present erected two generating sets each consisting of a 100 B H.P. Belliss steam engine, running at 500 revs. per min., direct-coupled to a 74kw. Parker dynamo developing 160 amperes at from 410 volts to 460 volts. The switchboard shown in one of our illustrations is of marble, with four generator and four feeder panels. It is fitted with Kelvin measuring instruments. About 7 miles of cable have at present been laid, the feeders being of triple concentric cable



GUERNSEY: BOILERS AND FEED PUMPS.

and the distributors of three-core cable. All the cables are lead covered and armoured. They have been manufactured by Callenders Cable and Construction Co. Storage plant has been erected in a battery room at the power station, and consists of 230 D.P. cells having an aggregate rated capacity of 715 ampere-hours at 80 amperes discharge. The battery, however, is capable of a maximum discharge of about 120 amperes.

Extensions, as already mentioned, are in hand. These include another Babcock and Wilcox boiler fitted with a superheater, and having 2,487 sq. ft. of heating surface; also another generating set consisting of a three-crank, triple-expansion Belliss 270 B.H.P. engine, running at 420 revolutions, direct-coupled to a Parker dynamo capable of giving 420 amperes at from 410 volts to 460 volts.

Although the supply of electric current at Guernsey is at present in the hands of a company, we understand that the States of Guernsey have made provisions for taking over the works and business at a future date, viz., at the end of 14 years, or subsequently at any multiple of seven years.

THE PARIS EXHIBITION.—V.*

(BY OUR SPECIAL CORRESPONDENT.)

Of the four large German machines in operation in the electricity building, that of the "Helios" company is probably the most striking. Its general appearance is shown in Fig. 22. Although only 1,020kw. single-phase was asked for by the exhibition authorities, the Helios Co. decided to exhibit a machine of larger capacity; and in order that a use might be found for it more readily after the exhibition was ended, the machine is designed so that it can generate either single-phase or three-phase alternating current, or, if required, both forms of current simultaneously. The machine conforms, therefore, more or less with the firm's standard 3,000kw. three-phase pattern, but it is wound with a main winding for 2,000kw, single-phase and an auxiliary winding for 1,500kw. three-phase, the latter being branched by the Scott connection from the middle of the main phase and its voltage being only $\sqrt{3}/2$ that of the main winding. Thus the machine can generate 2,000kw. single-phase with a power factor of 0·7, or 1,200kw. single-phase and 1,500kw. three-phase simultaneously. The pressure decided upon by the exhibition engineers was 2,000—2,200 volts at 50 ∿ per second, but here again the makers had in view the future disposal of the machine, and have built it in such a way that it can be connected in three parallel circuits to give 2,000 volts, in two parallel circuits to give 3,000 volts, or all in series for 6,000 volts.

Fig. 23 gives a front and end elevation of the machine, and also part sections of the armature and magnets on a larger scale. As is seen, the field magnet is made up of 84 poles, carried as usual by a casting which serves at the same time as the fly-wheel of the engine. The poles are circular in section, and each is fixed to the rim of the flywheel by two bolts. Pole-pieces are added of such a form and width as to make the curve of E.M.F. approximate as closely as possible to a sine curve. Each pole of the magnets is provided with a coil of bare copper wire wound edgewise; the total resistance of the existing coils is 0·7 ohm, and, assuming a power factor of 0·7, 24kw. (roughly 1 per cent. of the total capacity of the machine) is required for excitation at full load. As seen in Fig. 23, the poles are sunk in the casting of the flywheel, and the latter is covered in with boiler plates, presenting the unusual appearance shown in Fig. 22. These latter are in tension, and assist the arms in resisting the centrifugal force on the rim. The whole rotating part weighs 76 tons, of which about 3½ tons are represented by the windings on the magnet poles, and its diameter is 26ft. 8in., the external diameter of the armature casting being 30ft. 10in.

The armature frame is a casting of trapezoidal section (see Fig. 23) strengthened by radial arms, and supported at the bottom. The ring is in six sections. There are eight slots in the core per pole, of which six are for the main winding and the remaining two for the auxiliary winding. The latter is wound with cable of smaller section than the main winding.

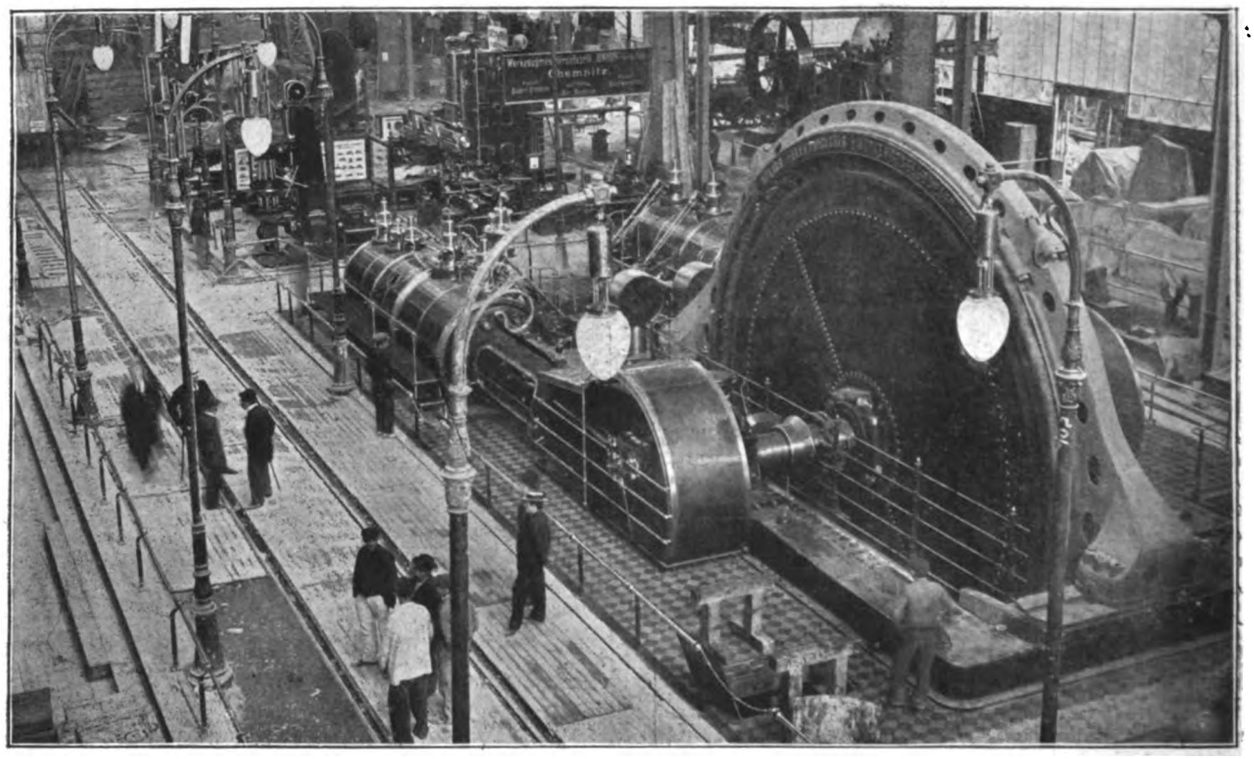

FIG. 22.—GENERAL VIEW OF "HELIOS" ALTERNATOR DRIVEN BY AUGSBURG ENGINE.

The exciter is considered as a separate exhibit, and is driven independently by a small vertical compound engine. It is six-polar, runs at 240 revs. per min., and furnishes 50kw. at 110 volts.

The engine driving the alternator is a horizontal triple expansion engine, with two low-pressure cylinders, and has been made at the Augsburg works of the Augsburg-Nuremberg Co. The main dimensions are as follows:—

Diameter of high-pressure cylinder	700mm.
„ intermediate cylinder	1,100mm.
„ each low-pressure cylinder	1,150mm.
Stroke	1,600mm.
Speed	72 revs. per min.
Steam pressure	12 atmospheres.
Cut-off of high-pressure cylinder	About 25 per cent.
Average capacity	1,600 H.P.
Maximum capacity	2,000 H.P.
Length over all	18·25 metres.
Width	8·9 metres.

All the cylinders and intermediate receivers are jacketed. The cranks have counterweights, and the brasses of the crank shaft bearings are in six parts. The two low-pressure cylinders are of course on opposite sides, placed in front of the H.P. and intermediate cylinder respectively. The valve

* Previous articles appeared in *The Electrician* of July 20 and 27, August 3 and 24.

Digitized by Google

gear is shown in the view of the engine given in Fig. 24. It is on the trip system, each cylinder being provided with four

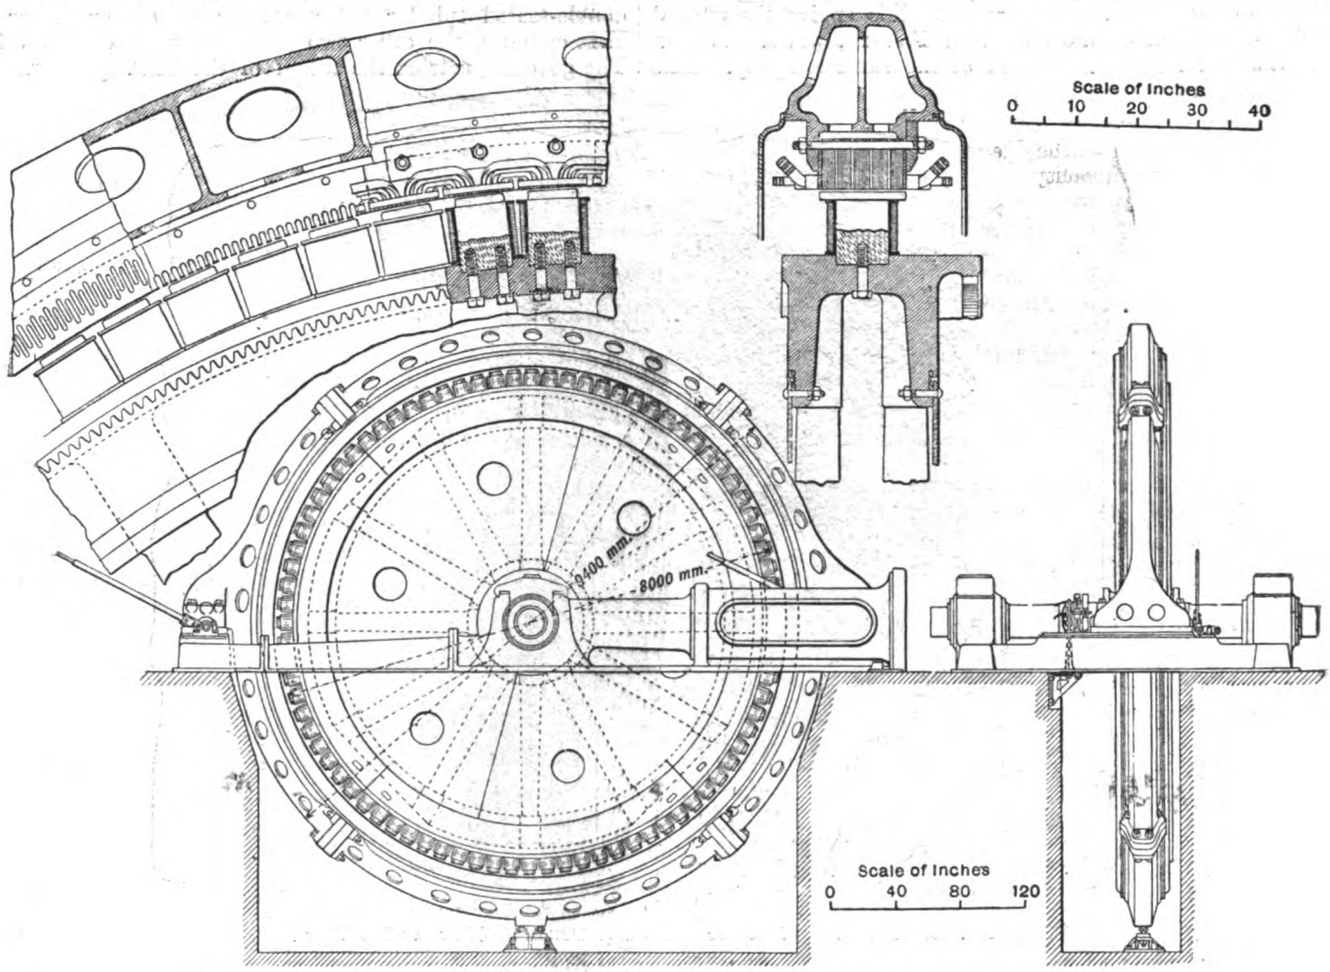

FIG. 23.—FRONT ELEVATION, END ELEVATION AND PART SECTIONS OF "HELIOS" ALTERNATOR.

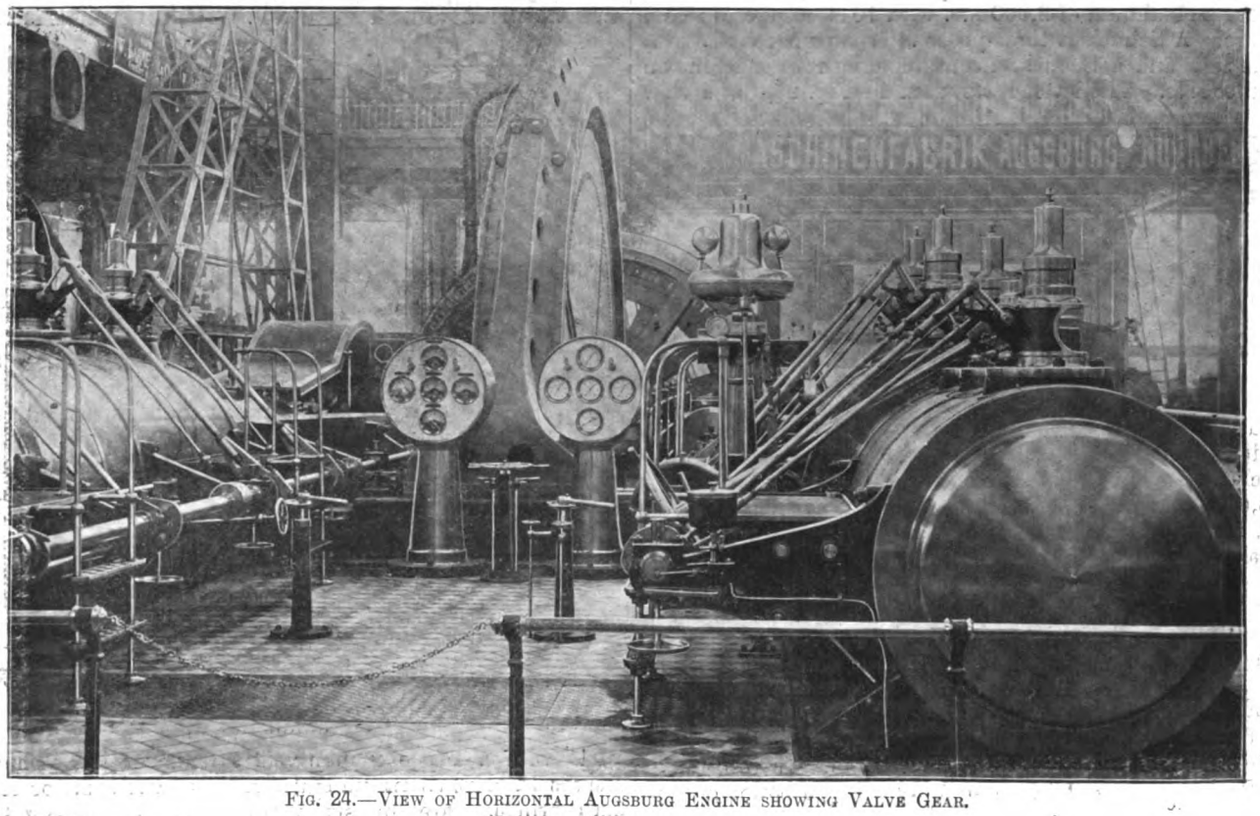

FIG. 24.—VIEW OF HORIZONTAL AUGSBURG ENGINE SHOWING VALVE GEAR.

double-seated valves, actuated by eccentrics and cams from wiper shafts, which are driven from the main shaft through bevel gearing. The governor acts on the cut-off of the H.P. cylinder, but it can be arranged to act on the intermediate cylinder if desired, or on the L.P. cylinder only. The cut-off can also be regulated by hand while the engine is running. If

Digitized by Google

required the engine can run as a tandem engine with the H.P. and L.P. cylinders only.

It is interesting to compare with this engine the vertical triple-expansion engine shown in Fig. 25, which has been built at the Nuremberg works of the same company. This engine is rated at 2,500 H.P., at a speed of 100 revs. per min., but at the exhibition it runs only at 83 revs. per min. and develops a maximum of 2,000 H.P. with 10 atmospheres steam pressure. A Schuckert three-phase alternator is coupled to it on one side, and a Schuckert continuous-current machine on the other side. The latter is not seen in Fig. 25, but a view of the dynamo alone is given in Fig. 26. The bed-plate of the engine is in three parts bolted together, and the castings supporting the cylinders are stiffened by pillars seen in Fig. 25. The H.P. cylinder is placed between the other two. Its diameter is 775mm., and the diameters of the other two cylinders are 1,200mm. and 1,800mm., with a stroke of 1,100mm. The H.P. and intermediate cylinders are jacketed, but only the covers of the L.P. cylinder. While a double-seated tubular valve gearing is employed for the H.P. cylinder, the other two are fitted with Corliss valves. The governor acts on the cut-off of the H.P. cylinder. The valve-gear shaft, placed behind the cylinders, is horizontal, and is driven by worm gearing. A noticeable feature is that this shaft is fitted with a flywheel. The crank shaft is in two parts with a flange coupling. Its diameter is 380mm., it weighs 14 tons, its length is 9 metres, and it is supported on six bearings.

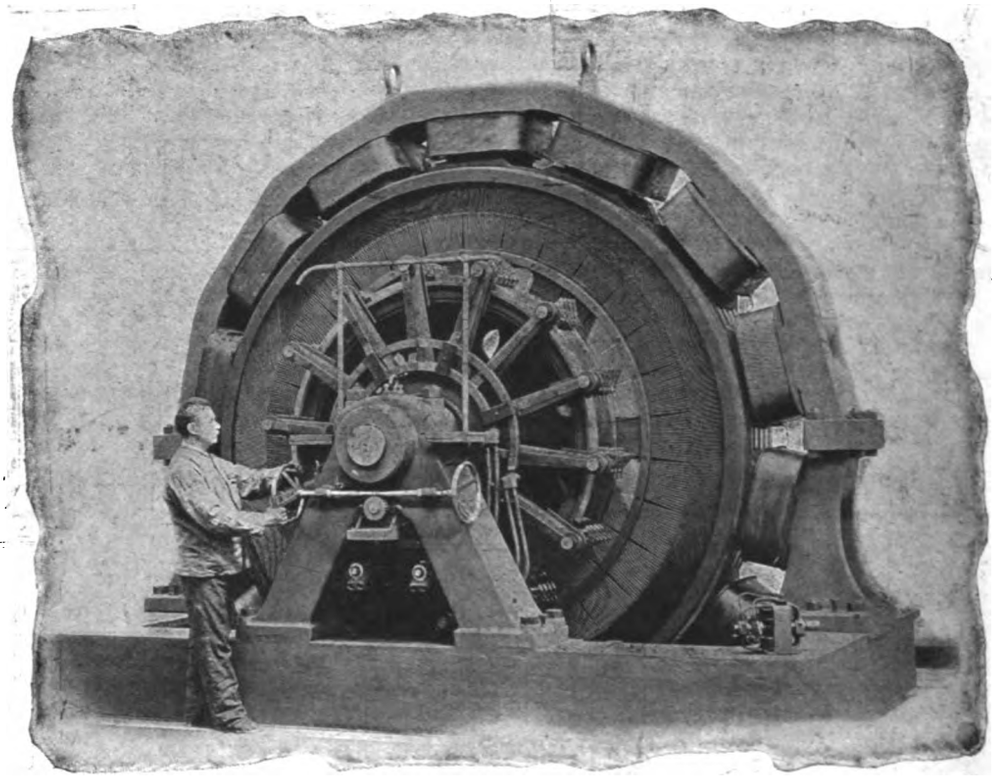

FIG. 26.—SCHUCKERT CONTINUOUS-CURRENT DYNAMO, 900KW. AT 500 VOLTS.

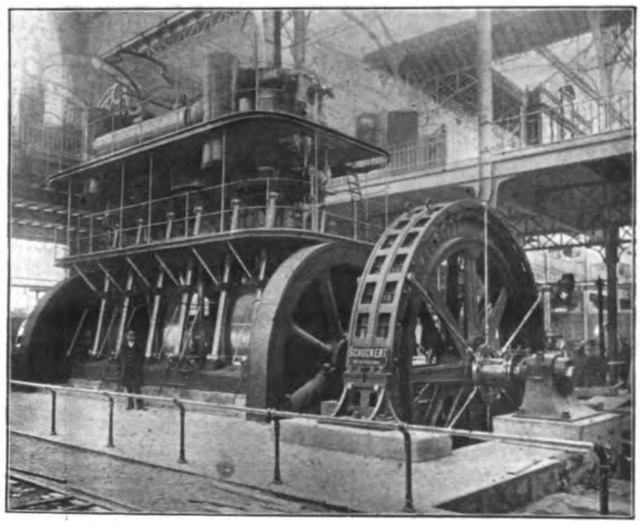

FIG. 25.—2,500 H.P. AUGSBURG-NUREMBERG ENGINE DRIVING 900 KW. CONTINUOUS-CURRENT DYNAMO AND 850 KW. 3-PHASE ALTERNATOR.

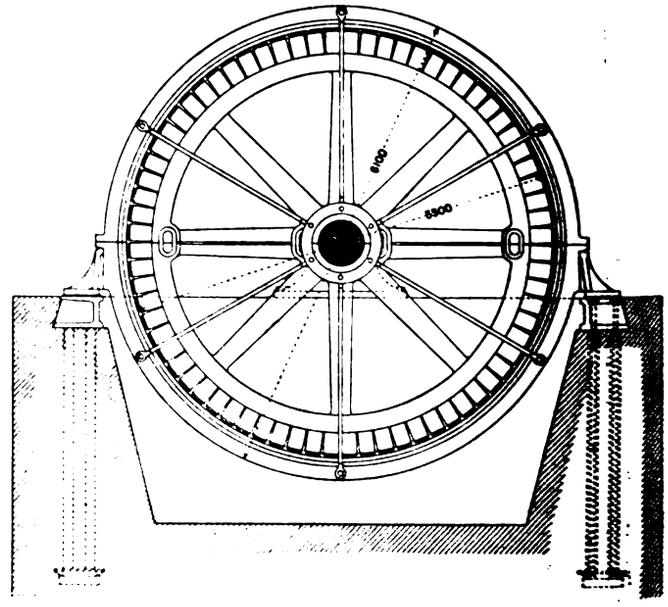

FIG. 27.—ELEVATION OF SCHUCKERT THREE-PHASE ALTERNATOR, SHOWING METHOD OF STIFFENING ARMATURE.

While the French dynamos are frequently driven by single-cylinder engines, it appears that some of the German makers have on the other hand made up their minds to secure an even

Digitized by Google

turning movement at all costs. This triple-expansion engine, in addition to the rotating magnets of the alternator, which weigh 26 tons, has two flywheels, one on either side, weighing each about 20 tons. I understand that this is because the engine is to be employed for a tramway power-house, Mr. Raworth's doctrine of light flywheels for traction generators not having found any more favour in Germany than in this country.

On this engine, as on several others, an electric motor is employed for "barring," the exhibition engineers having expressed a wish that auxiliary plant should be motor-driven as far as possible. The motor is a Schuckert continuous-current one, developing 10 H.P. at 600 revs. per min. It is so geared that it can turn the flywheel a complete revolution in three minutes.

The continuous-current dynamo (Fig. 26) has been built for a capacity of 900kw. at 100 revs. per min., but at the exhibition it is only run at 88 revs. per min. and can develop 750kw. at 500 volts. As seen in the illustration, it is of the external-pole type, the magnet casting being in two parts and maintaining 14 poles fitted with pole-pieces. The armature core is smooth, not slotted or tunnelled. It is made up of core-discs and paper in the usual manner, and is drum-wound with windings of rectangular section. The bars are spaced in groups, and the end connections curved to facilitate

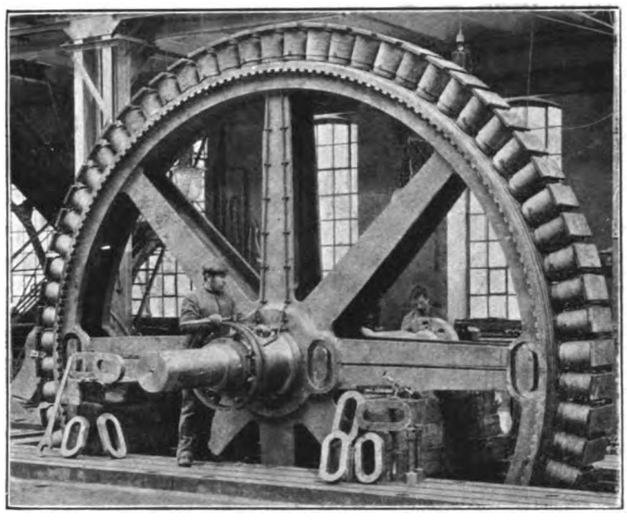

FIG. 28.—FIELD MAGNETS OF SCHUCKERT THREE-PHASE DYNAMO.

ventilation. Mica is used to insulate the binding-on wire from the winding. The commutator has 536 segments. The weight of the whole dynamo is about 45 tons.

The feature in the three-phase machine that attracts attention is the peculiar way in which the armature frame is stiffened by radial bars starting out from a ring concentric with the shaft, but of course clear of it by some inches. This construction, clearly seen in Figs. 25 and 27, is also adopted on one of the French alternators, which appears, however, to be similar in some other respects to the Schuckert machine, and is therefore possibly the work of a designer trained at the Schuckert works. The capacity of the Schuckert three-phase dynamo is 850kw. on a non-inductive load, at a pressure of 5,000 volts. The dimensions marked in Fig. 27 are in millimetres. The armature core is built up of soft iron sheets held in the ring-shape casting in the usual manner, a gap being left between sets of core discs, so that the armature may be ventilated satisfactorily. The method of supporting the armature casting is seen in the illustrations; to turn the armature round in order to repair the lower portions the brackets which support it on the bed-plate beams are removed. The lower part of the armature casting weighs 7·75 tons, and the upper portion 6·6 tons. Fig. 28 shows the magnet wheel of the machine in process of construction. The wheel is a steel casting, and 72 poles are bolted to its rim in such a manner that by removing two screws any pole can be pulled out sideways without disturbing the remaining parts of the machine.

There are two separate pillars for the continuous-current and three-phase switches. The former is fitted with both maximum and minimum automatic cut-outs, in addition to the usual apparatus for a dynamo panel. In conformity with the customary German practice, the measuring instruments of the high-pressure machine are connected to the secondaries of small transformers made for the purpose, and only these low-pressure instruments and the handles of the switches are on the front of the board. The high-pressure switch (Fig. 29) is of interesting construction.

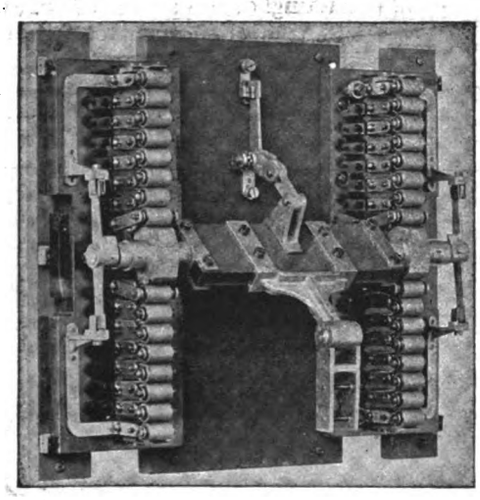

FIG. 29.—SCHUCKERT HIGH-PRESSURE SWITCH.

It consists of a number of metal rollers mounted on flat springs in such a way that each roller can revolve freely about its own axis. When the double cam, connected to the handle of the switch, is turned in the vertical position seen in the figure, corresponding to the "On" position of the handle, the rollers make contact with one another. A strong flat spring presses against each of the end rollers. When the cam is in its horizontal position the rollers are no longer in contact, and both when switching on and off they turn slightly, so that a rubbing contact is produced and a fresh contact surface is always exposed.

THE ST. GABRIEL-QUEBEC TRANSMISSION PLANT.

This scheme provides electrical energy, generated by water power at St. Gabriel, for transmission at high pressure to Quebec. The system, owned by the Jacques-Cartier Water

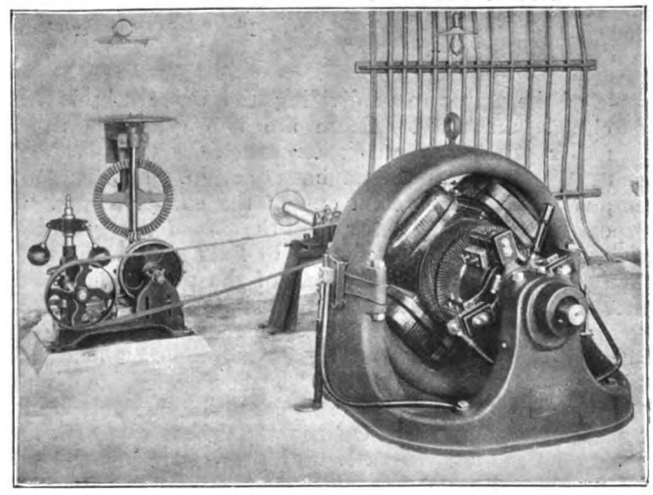

FIG. 1.—ONE OF THE EXCITER SETS.

Power Co., commenced operations in February last. At St. Gabriel, on the river of the same name, there is a fall of 20ft. on a rapid of 200yd. length; at the head of this rapid is

Digitized by Google

the dam, a strongly-built stonework structure, 300ft. in length. The generating station is situated in a depression near the river and about 270ft. below the dam. The water is conveyed by two penstocks 13ft. in diameter to two Morgan-Smith turbines in the power-house. The wheels run at 150 revs. per min., and are each direct coupled to a 750 kw. Westinghouse three-phase generator, producing current at 2,000 volts pressure at a frequency of 60 periods per second. The two small exciting machines (Fig. 1) are also each coupled to a separate water motor. These sets run at 350 revs. per min. the generators being of the Westinghouse type of 37kw. capacity, and 125 volts pressure. The arrangement of the electrical machines is well shown in Fig. 2, as is also the position of the switchboard. The switchboard is mounted on a gallery standing against the partition which runs right along the centre of the power room dividing the water wheels from the electric machines. There are two generator panels, two feeder panels and an exciter panel, the whole being of the usual well-known Westinghouse design. A small rotary pump is driven by belt from one of the exciter shafts. Its purpose is to draw any water from the pits of the generating machines which may collect there by leakage from the water-wheels or condensation. The half of the power-house at the other side of the partition is divided into three floors. On the ground floor are the turbines. A room on the first floor is used as the transformer room, wherein are six 250kw. self-cooling, oil-insulated Westinghouse transformers, stepping up the generating pressure of 2,000 volts to the transmission line pressure of 20,000 volts. On the top floor are installed the choking coils of the Wurt's lightning arresters and the extra high-pressure cutouts.

Current is transmitted by overhead lines to Quebec, a distance of 18 miles. The pressure is reduced in a sub-station situated just outside the city boundary. The sub-station is a brick building 15ft. square, which receives from the overhead lines the 20,000 volt three-phase current and transforms it to 2,200 volt two-phase. This is then transmitted direct to a main distributing board in the centre of the city, distant about one mile, from which mains are branched off to various transformer sub-stations. The pressure of the 2,200 volt feeders is regulated from this main switchboard, pilot wires from various points of the house distribution network being brought to voltmeters here. The substations contain transformers which reduce the feeder pressure from 2,200 volts to 220 volts, which is distributed to the customers on the three-wire system.

Very low prices are charged for current. A flat rate charge is made of 0·5d. per lamp per day, or one farthing per 16 c.p. lamp per hour. The operating expenses of the plant are exceedingly low, and the supply is remunerative with these low charges. Only four men are required for the attendance of the generating plant, two by day and two by night, the wages account amounting to not more than £50 per month.

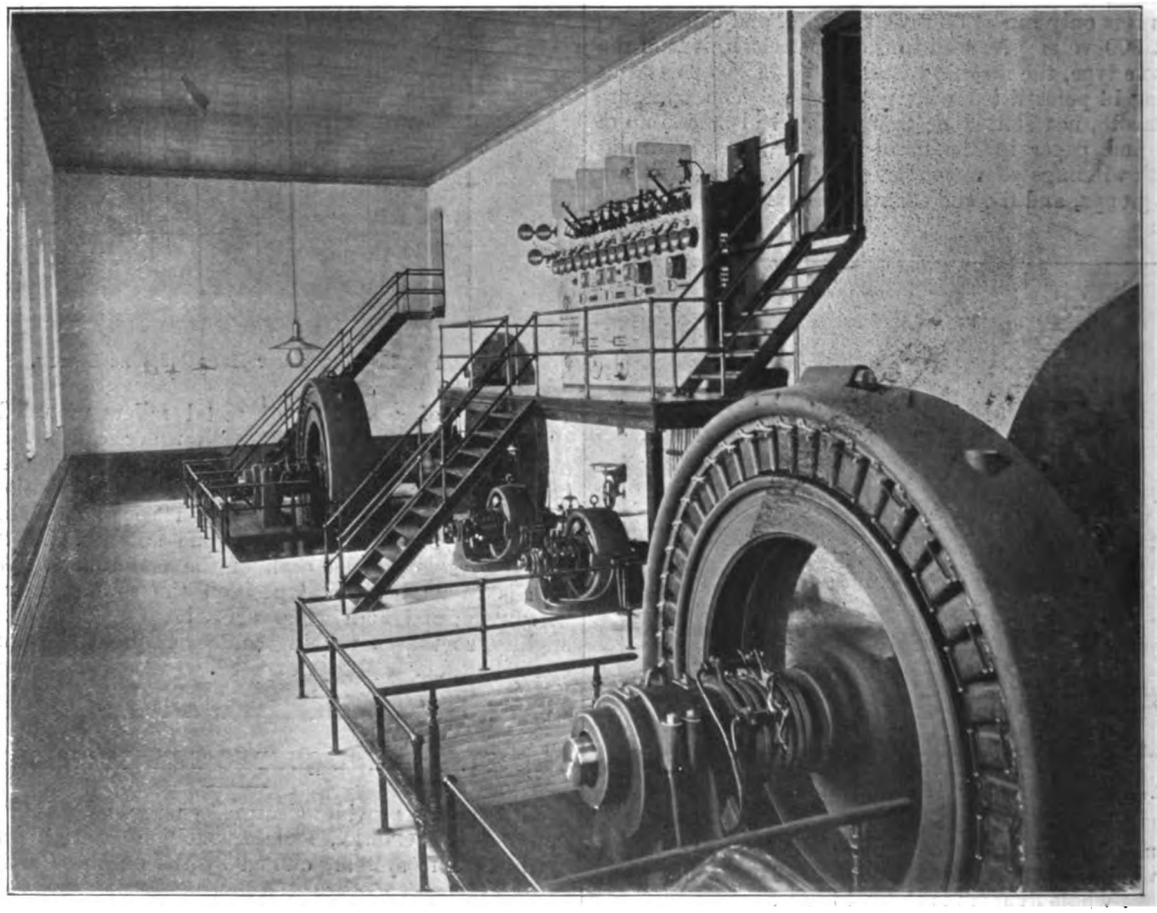

FIG. 2.—MACHINERY ROOM AT ST. GABRIEL POWER STATION.

THE ELECTRIC DRIVING OF IRONWORKS AND ROLLING MILLS.*

BY O. LASCHE.

The Allgemeine Electricitäts Gesellschaft of Berlin has been driving the rolling mills of its Oberspree cable works by electric motors for the past year and a half. A view of the copper rolling mills is given in Fig. 1. In a shop 66ft. wide and 148ft. long, are the rough rolls with four frames and the fine rolls with seven frames. The rolling mills were built by the Gebrüder Klein of Dahlbruch. The rough rolls make 108 revs. per min., and are driven through ropes by a three-phase motor. The motor develops an average of 200 H.P. at a speed of 380 revs. per min. at 500 volts, and the diameters of the driving and driven pullies are 4ft. 7in. and 16ft. 5in. respectively. It was decided at the time to gear down, although it is possible to build three-phase motors with

* Abstract from the *Technisches Centralblatt.*

Digitized by Google

the requisite slow speed. The fine rolls are driven by a 400 H.P. motor at 420 revs. per min.; this motor is direct-coupled, and a flywheel is employed.

In 11 hours the two sets of rolls can roll out 27 tons of copper from bars weighing about 130lb. and 12·4 sq. in. sectional area to wire of 7mm. (0·275in.) diameter—*i.e.*, about 12½ miles of wire per diem. As the present plant is fully occupied with copper wire and strip, two new sets of rolls are to be built in the adjoining room for producing trolley wire. Power is taken from a neighbouring supply station. During the one and a-half years the works have been in operation no interruptions have occurred, and the installation has given the fullest satisfaction. The advantages, as compared with steam driving, are quick, reliable work, saving of space and of attendance to the motors, and increased light and cleanliness. The output is considerably higher than with steam driving.

In large ironworks hitherto many dozen steam engines, of various sizes, and separate boilers are employed, and the circumstances are usually such that the full advantages of superheating, economisers, a common condensing plant, &c., cannot be enjoyed. Experiments have shown that the blast furnace gases can be employed in gas engines, and units up to 1,000 H.P. have been successfully built for this purpose. But even in cases where neither water-power nor blast-furnace gases are available, and where, in consequence, steam engines and boilers must be used, the centralisation of the power-generating plant rendered possible by electrical distribution has great advantages.

The three-phase motor has no commutator and requires no attention and practically no repairs. It can therefore, if desired, be placed in a fairly inaccessible position, and this, together with its little sensitiveness to dust and dirt, renders it easier than other motors to combine with the machines it is to drive. The simple design and low weight of three-phase motors cause their price to be lower than those of other types.

Having regard to safety, a higher pressure than 500 volts should not be employed for continuous currents. With alternating currents pressures of several thousand volts can be used without hesitation, and 30 H.P. motors even are built for 2,000 volts. Thus alternating currents require only smaller conductors, and the aggregate sectional areas of the conductors for three-phase distribution is less than that for single or two-phase.

The simplest form of motor is that with a short-circuited armature. Small motors can be started and stopped by an ordinary three-pole switch, and up to 5 H.P. or 10 H.P. motors the turning moment at starting is nearly double the normal turning moment during running. Larger motors can also be employed with short-circuited armatures by starting the motor and dynamo at the same time. This method of working is employed most frequently for electrically-driven drainage or pumping systems. The motors are switched on before starting or else are never switched off. They are thus, so to say, electrically coupled with the generators and run up to speed with them. For starting with higher turning moments and as slowly as desired, adjustable resistances are placed in the armature circuit. This also enables the speed to be regulated between wide limits while running. By this arrangement, the three-phase motor can develop at starting up to three times the normal turning moment, and thus the armature with slip rings should be employed wherever the motor has to be started on full load. If the slip rings are only to be employed for starting, a device is added to short-circuit the armature within itself after the motor has run up to speed, so that the brushes can be lifted from the slip rings.

The speed of the three-phase motor decreases by a certain percentage as the load increases. This effect of slip of the motor armature may be compared with the slip of a belt on a pulley. If no power is being taken from the countershaft, and the pulley is therefore running light, the slip is quite small and the speed of the belt is but very little greater than that of the pulley. But if power is taken from the countershaft to enable the pulley to exercise a turning moment, the slip of the pulley increases—*i.e.*, the pulley lags behind the driving belt. A similar phenomenon takes place in

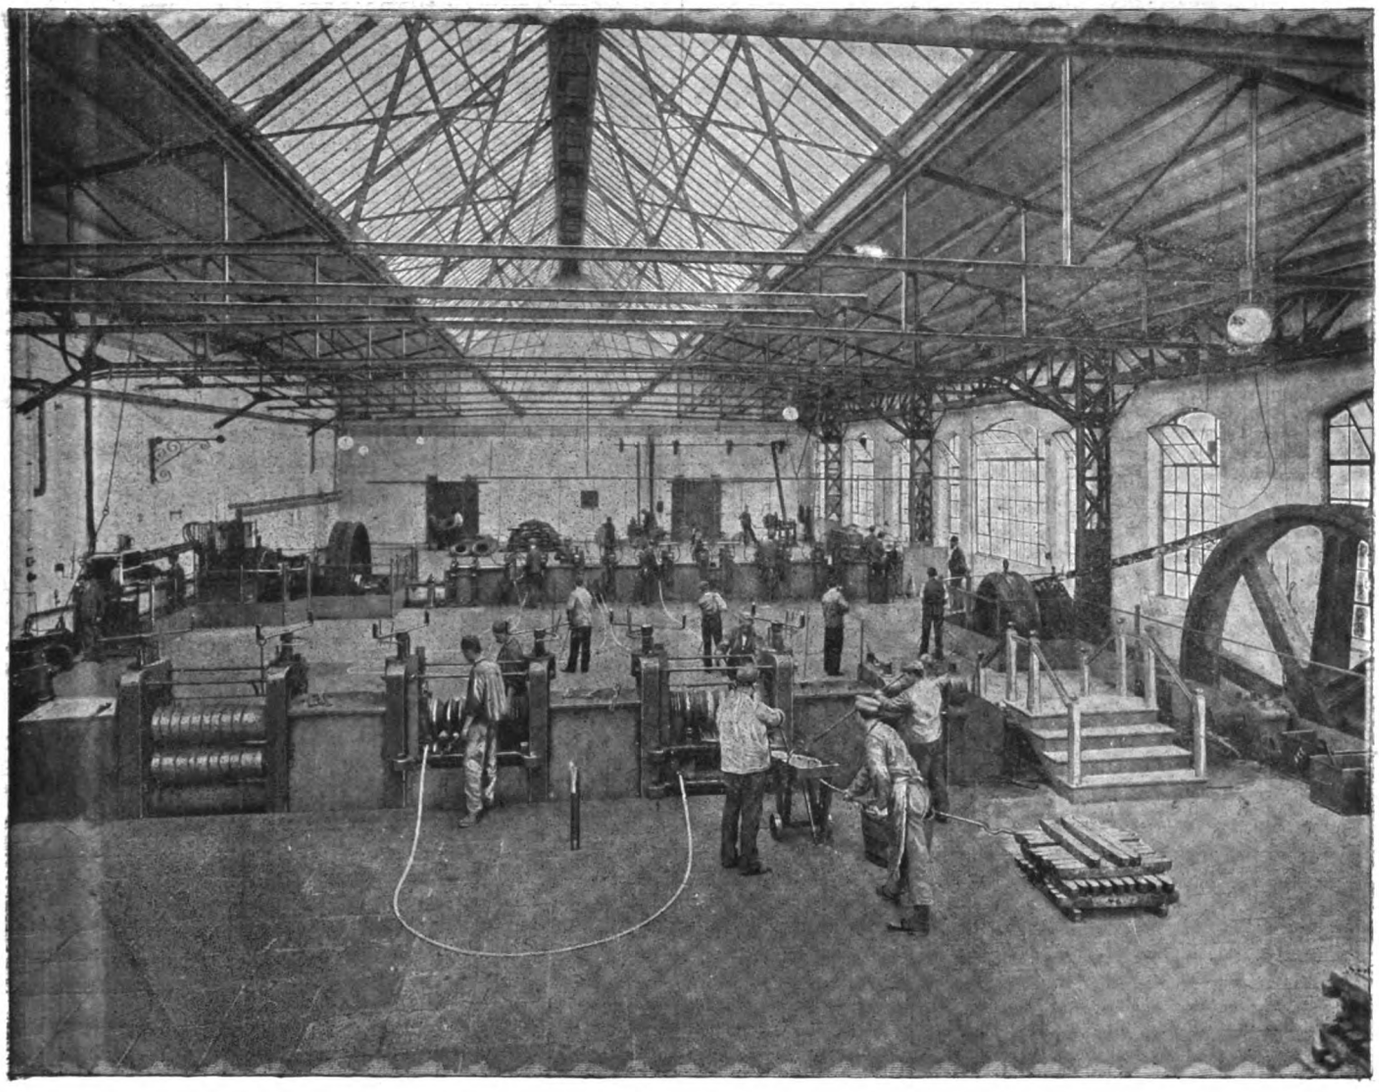

FIG. 1.—ELECTRICALLY-DRIVEN COPPER WIRE ROLLING MILLS OF THE ALLGEMEINE ELEKTRICITÄTS-GESELLSCHAFT.

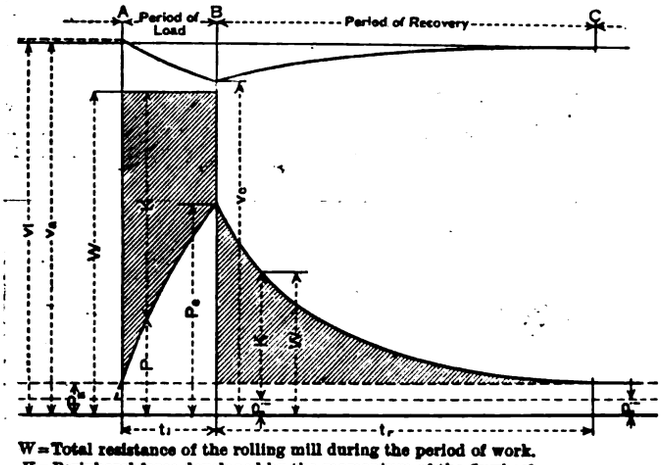
Digitized by Google

the three-phase motor in the mutual action between the armature and the so-called rotatory field of the stator winding. When the armature is delivering no power to its shaft it rotates with approximately the same speed as the rotatory field, but as the load increases the armature begins to slip, that is to say it lags behind the field. This slip of the motor is within the limits of normal load, approximately proportional to the increasing load. For instance, if it amounts to 1½ per cent. at half load, it will be about 3 per cent. at full load. In designing a three-phase motor, the slip can be taken at a less or greater value, and the speed of the motor with increasing loads



W = Total resistance of the rolling mill during the period of work.
K = Peripheral force developed by the momentum of the flywheel.
P = Peripheral force developed by the motor.
P_l = Peripheral force developed by the motor when the rolling mill is running light.
P_a = Peripheral force developed by the motor at the commencement of the period of load.
P_e = Peripheral force developed by the motor at the end of the period of load.
v_l = Peripheral speed at no load.
v_a = Peripheral speed at commencement of period of load.
v_e = Peripheral speed at end of period of load.
t_l = Duration of the load in seconds.
t_r = Duration of period of recovery in seconds.

FIG. 2.

will drop more or less accordingly. This slip of motors represents a small percentage loss, just as in the case of belt driving.

Having regard to the efficiency of the motor, therefore, as small a slip as possible is desirable in motors for ordinary work. In the case of electrically-driven rolling mills, however, it is the total efficiency of the installation that has to be considered, which, in view of the general advantages, may be very high, even with a large slip. Through this property of slip—viz., that speed the motor diminishes as the load increases—the momentum of a flywheel can supply momentarily a part of the requisite power. Thus the motor might

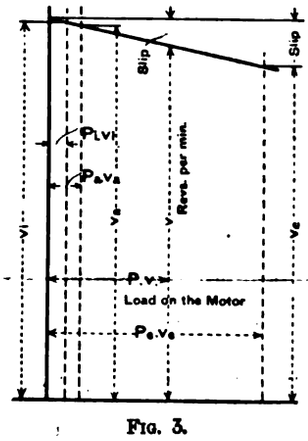


FIG. 3.

be considerably smaller than corresponding to the maximum mechanical resistance it has to overcome.

In what follows, the working of flywheel rolling mills only will be dealt with; motors for driving reversing rolls will not be considered, since they come under entirely different working conditions. It will first be examined in what way the motor must be reinforced by the flywheel, and what are the considerations to be made in calculating the size of the motor and the flywheel energy. We must consider two main periods in the cycle of operations: first, that in which work is done, and, secondly, the period of recovery. The latter implies the time during which the motor stores up energy in the flywheel to be employed usefully in the next period of work. Assuming that the resistance (P_l) of the motor and rolling mill when running light and also the total resistance (W) of the rolling mill are constant during the working period, the following relations are obtained, in which all the forces and peripheral velocities are reduced to a radius of 1.

Period of Load.—To overcome the resistance W during the working period, we have the peripheral force of the motor and that part of the momentum of the flywheel which is liberated by the drop in the speed—*i.e.*, $W = P + K$, where K is the part

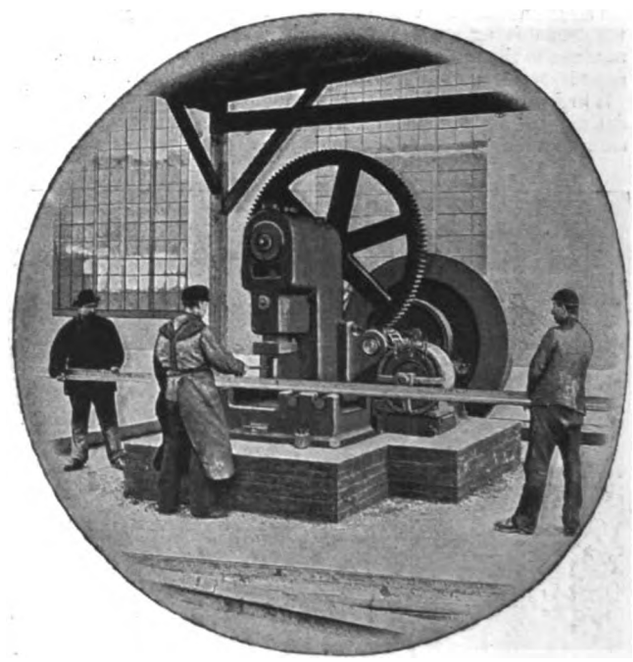

FIG. 10.—Straightening Machine.

contributed by the flywheel. During this period the speed falls from V_a to V_e as shown in the portion A B of the top curve in Fig. 2. This upper curve gives the variation in V, while the lower curve shows the varying relation between K and P—*i.e.*, the relation between the power supplied by the motor and that supplied by the flywheel. In the fundamental equation $W = P + K$, $K = m\frac{dV}{dt}$.

The determination of P is made in Fig. 3, in which the velocities V for the various loads P V of the motor are marked off. The relation between V and P V in a three-phase motor is taken as a straight-line one, for greater convenience in the calculation. Suppose, at the commencement of the period of load the actual resistance corresponding to no load has not yet been reached, and let the momentary value of V be V_a, somewhat smaller than V_l, which is the speed at no load; and let the value of PV be $P_a V_a$. The values of V_a and V_e corresponding to $P_a V_a$ and $P_e V_e$ are known from the dimensions of the motor. Then we have

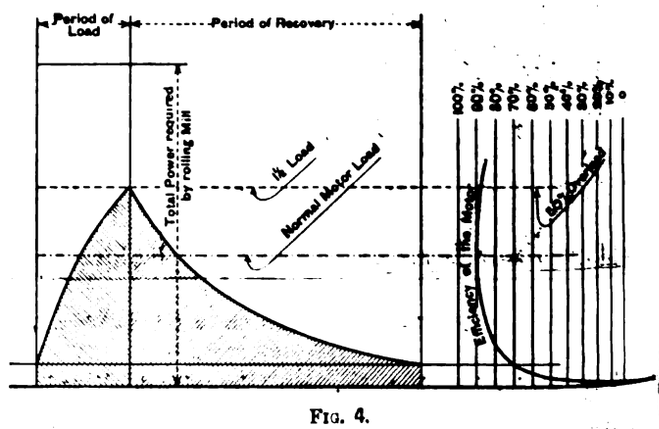

FIG. 4.

$$P = \frac{P_e V_e (V_a - V) + P_a V_a (V - V_e)}{V(V_a - V_e)}$$

Digitized by Google

Inserting these values of K and P in the fundamental equation, we get

$$W=\frac{P_e V_e(V_a-V)+P_a V_a(V-V_e)}{V(V_a-V_e)}+m\frac{dV}{dt}.$$

From this the equations of the curves for P and V as functions of the time may be developed, and we can plot off for each second the constant light-load resistance P_i and the resistance K which the inertia of the flywheel opposes to its acceleration. At each moment $P=K+P_i$. The curves between B and C show the increase in the velocity and the diminution of the peripheral force P required from the motor. In the fundamental equation, $P=K+P_i$, K has exactly the same value as during the period of load, viz., $K=m\frac{dV}{dt}$. The

reduction in speed of the flywheel and the corresponding load on the motor.

Period of Recovery.—The flywheel must be accelerated by the three-phase motor from the velocity V_e at the end of the period of load to the velocity V_a which it is to have at the commencement of the cycle. During this period the motor has to overcome the value of P is obtained from Fig. 3, and is

$$P=\frac{P_e V_e(V_i-V)+P_i V_i(V-V_e)}{V(V_i-V_e)}.$$

Inserting those two values in the fundamental equation, we have

$$\frac{P_e V_e(V_i-V)+P_i V_i(V-V_e)}{V(V_i-V_e)}=m\frac{dV}{dt}+P_i,$$

Digitized by Google

and from this the curves for P and V can be determined as before. With the assistance of the formulæ derived for P and V out of these equations, the curves in Figs. 5 to 7 are calculated and plotted. In all the examples the power required by the rolling mill during the period of work has been assumed to be constant, as also the power required when running light.

It may be added here that the efficiency of the motors is nearly constant within very wide limits, or at least only drops to some 85 per cent. (see Fig. 4).

the periods of recovery as well as the flywheel weights increase proportionally with the duration of the period of load, and, therefore, that for long periods of load heavy flywheels must be chosen, and there must be long periods of recovery.

In Fig. 7 another set of three examples is plotted, in which the period of work and the size of the motor are assumed to be fixed. Three different values for the slip of the motor are chosen, and the necessary flywheel weight and period of recovery calculated. The smaller the slip allowed, the larger must be the dimensions of

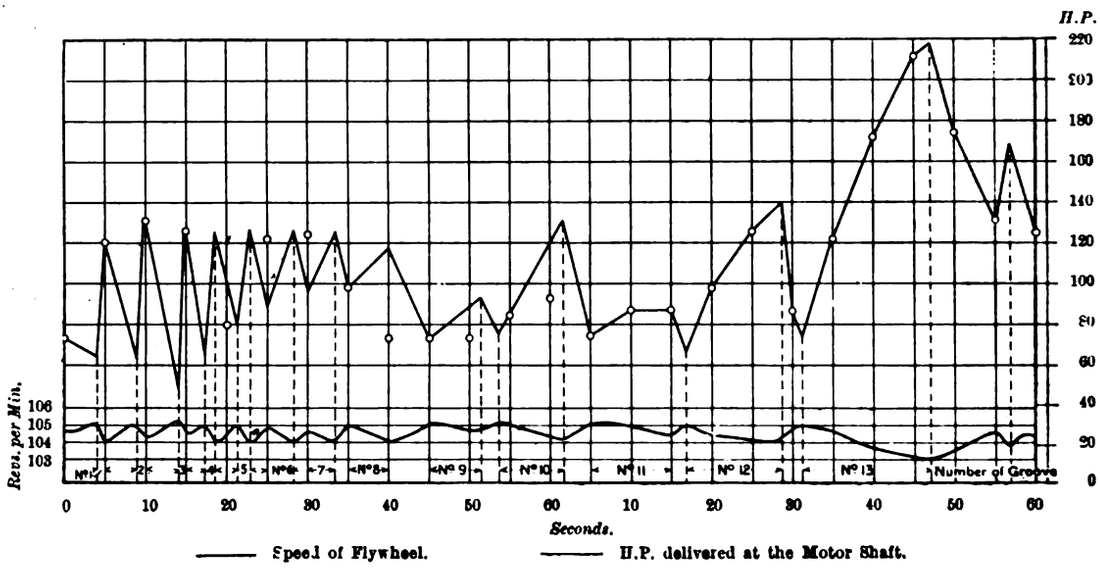

FIG. 8.—Rough Rolls. Motor N D 2,000 (rope drive).

In Fig. 5 three examples are worked out, in each of which the duration of the period of load as well as the slip of the motor (i.e., the decrease in speed owing to increase in load) is taken at the same value. A different size of motor has been taken in each case, however, and the necessary weight of flywheel and time required for recovery has been calculated. As maximum load on the motor one and a-half times the normal load has been assumed. It follows from these diagrams that when there are only small pauses between two roller grooves, and thus only a short period of recovery, a large the flywheel. In the curve to the right of this figure the values of the slip are plotted as abscissæ and the flywheel masses as ordinates. These diagrams show how much the necessary flywheel weights are diminished by increasing the permissible slip.

The results of measurements of power consumption and velocity in the rough and fine rolling mills at the cables works of the Allgemeine Elektricitäts Gesellschaft are represented graphically in Figs. 8 and 9. The speed measurements were made with a tachometer. To determine the power developed by the motor, voltmeter, ammeter and

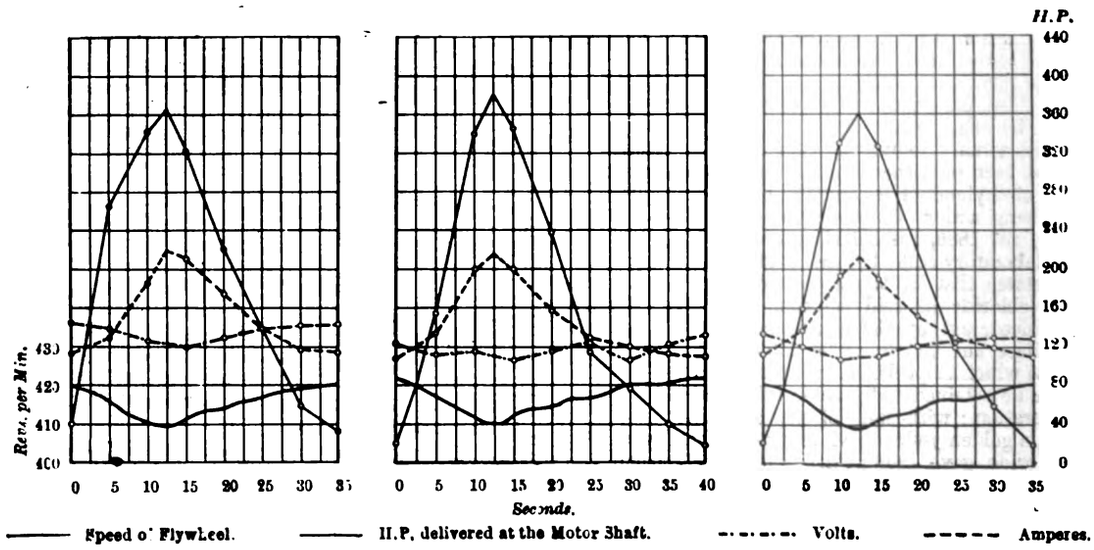

FIG. 9.—Wire Rolling Mill. Motor N D 6,000 (directly coupled).

motor in connection with a light flywheel must be chosen, while with longer waits between two individual grooves a smaller motor with a correspondingly heavier flywheel suffices. In Fig. 5 also the weights of flywheel necessary for the various sizes of motor are sketched as mathematically equivalent flywheel masses.

In Fig. 6 a comparison is again made of three examples, but here the sizes of the motor and of the slip are taken the same in the three cases, and the duration of the period of recovery and the necessary flywheel weights determined for different periods of load. From this diagram it is seen that if the size of the motor remains the same, wattmeter measurements were taken every five seconds, the efficiency of the motor being known.

In other machines, such as stamping machines, shears, presses, straightening machines (Fig. 10), &c., in which short periods of work alternate regularly with short periods of rest, and are therefore provided with flywheels, the determination of the size of the flywheels and motors is determined on the same lines as for rolling mills. It is to be noticed, however, that, in these other machines, the period of recovery is comparatively great compared with that of the period of load, so that a fairly small size of motor can be selected.

ELECTRO-CHEMISTRY IN A DYE AND PRINT WORKS.*

BY A. E. SUNDERLAND.

The action of the electric current upon dyewares and intermediate products may be brought about in several ways, of which the following are the most important: The action of the electric current upon the substance itself, at the ordinary temperature if a liquid, or if a solid, above its melting point. The action of the current upon the body dissolved in some solvent. This gives the best results.

The first method does not give such good results as when dealing with inorganic substances, for it is too severe in its action, and usually resolves the compound into its elements. Certainly, intermediary products are formed, but these are so difficult to isolate that as a commercial method it is not to be recommended. Most members of the aliphatic and aromatic series in a molten state can be resolved into CO_2+H_2O, &c., with the production of intermediate products such as oxalic acid and glycollic acid in the aliphatic series, and hydroquinone ethers and hydro-oxy carboxylic acid in the aromatic series. The simplest apparatus employed consists of two tubes joined together by a water-tight V joint, each leg containing a circular disc pole. The dimensions of the tube, the quantity of liquor, the strength of the current, and the amount consumed should all be known.

The nature of the products obtained by the electrolysis of organic bodies depend upon two things—(1) Whether the body is a good electrolyte or not, and if not, what bodies are used to make it so. (2) Whether the decomposition takes place in an acid or alkaline medium; totally different products being usually obtained by electrolysis in each medium. The primary action which takes place in an electrolytic cell is an oxidising action at the positive pole and a reducing action at the negative pole, and the best results are got by adapting the process so that the products thus formed are immediately removed from the field of action. This may be done in several ways.—(1) Automatically by making use of the different densities of the solutions. (2) By raising or lowering the temperature of the cell. (3) By using different electrolytes in the anode and cathode chamber. (4) By using such an electrolyte that the body formed is totally insoluble in it, and thus falls out of solution, and is unacted upon by the current.

The chief interest in the electrolysis of organic compounds centres in the behaviour of the hydro-carbon radicle, which both in the aliphatic and the aromatic series seems to be very stable. The most important reactions are, however, the reduction of aromatic nitro bodies in alkaline solution, first to azo compounds and then to hydrazo compounds, these changes being produced in a very satisfactory manner, and the yield being equal nearly to the theoretical. If the same electrolyte is used in the anode and cathode chambers, the electrical osmosis is very noticeable, and is one of the chief difficulties in adapting these processes on the large scale, and the results obtained tend to emphasise the law of Clausius and Hittorf, that the electric current does not overcome affinities, but that the chief reactions are produced by the primary electrolysis of the electrolyte into hydrogen and oxygen.

As regards the actual production of dyestuffs by electricity, very few results have been published, and the known cases, such as the production of methylene blues, alizarin black, &c., simply depend upon the oxidising action of the electric current in the anode cell. Goppelsroeder, in 1886, published several results which he had obtained on a laboratory scale by the oxidation of various primary amines. He states that by the action of the electric current on aniline hydro-chloride in acid solution, emeraldine and aniline black are produced, and by the electrolysis of aniline salt alone a brown precipitate and red to violet colouration only is obtained. Further results which Goppelsroeder recorded are as follows: With methyl aniline he obtained a blue colouration; with diphenylamine, a violot colouration; with salts of napthylamine, brown bodies; with napthol, a golden yellow; while magenta, methyl alcohol, and potassium fluoride gave Hoffmann's violet. Goppelsroeder also produced aniline from nitro-benzene, and alizarin from anthraquinone.

Electricity may be applied in the dyeing process itself in two ways—(1) in printing, (2) in the dye bath. With regard to electric printing, Goppelsroeder proceeded as follows: A plate of lead or other suitable conducting material is used as the negative pole, and the stencil pencil or plate is used as the positive pole. Between these is fed the cloth impregnated with the various chemicals. On passing the current, decomposition of the various chemicals take place wherever the stencil plate touches, and the design is produced. As instances: (1) If the cloth be impregnated with an acid solution of aniline salt an aniline black figure is produced. (2) If the cloth be impregnated with potassium thiocyanate a yellow to orange figure is produced. Goppelsroeder also found that some dyes, such as Turkey red and indigo blue, could in the same way be discharged white by the electric current, and thus, by combination with the aniline black and canarin yellow, he could produce white, black, and yellow prints on red or blue ground. If metallic oxides were used, the oxide was precipitated, and the cloth, on dyeing with alizarins, would show a design where the current had passed.

These results, as obtained by Goppelsroder, are very interesting, and with the azo dyes some equally interesting results have since been obtained. The diazo compounds are so unstable that they are decomposed by ordinary daylight. I have subjected such to the ordinary current, and find that with a current of 20 volts to 40 volts 5 amperes a five seconds' contact will in some cases cause the decomposition, and on developing, the print will remain undeveloped. This discharge, however, is not quick or good enough, but it can be intensified by mixing along with the diazo compound a certain amount of sodium chloride, nitrate, chlorate, or other suitable chemical, which will, on the passage of the current, liberate compounds capable of discharging the diazo compound more thoroughly. Such reactions may be greatly extended, and by making use of the colours themselves instead of bases which contain the amido group, some very useful effects can be obtained, such as, for instance, with rosaniline, red and dark brown patterns can be obtained; with safranine, red and dark blue; and with cyanole some very peculiar combinations can be obtained. Cyanole on diazotising becomes yellow, but wherever exposed to air or some oxidising agent, such as an electric current, it turns a fine peacock blue shade, and on washing the print with a phenol or soda the effect is permanent. This, along with the use of bases such as thiotoluidines, gives some useful results. Another branch of printing by electricity, which also offers some very interesting information, is the combination of organic cases along with the use of metallic anodes. This may be made use of for the production of effects of the opposite kind to the above, and most certainly in cotton and paper printing it is worth experimenting with.

There are only two machines I have seen recommended for electrical dyeing, and these in no way offer any advantage over ordinary processes. From my own experiments, I consider that a machine for this purpose should fulfil the following requirements: (1) The poles must not be of metal, but of carbon or biscuit porcelain, which conduct by becoming saturated with the electrolyte. (2) They must be as near to one another as possible. (3) The cloth must pass between the poles in the open width. (4) The poles may be perfectly smooth, and preferably cylindrical, revolving freely. These particulars are necessary, because in the ordinary passage of the electric current across any dye solution, the tendency of the dye is to concentrate itself around the negative pole, and not to circulate freely in the whole dye vessel, thus there is always a great danger of unevenness.

In the finishing of goods the peculiar effect which is produced by calendering a piece in two different directions, one impression upon another, is well known. This is technically termed water-marking or moire, and is due to the irregular reflection from the surface of the material, one part of the light being totally reflected, and the other part dispersed. This effect can be introduced in several ways. One way is by displacing the warp or weft threads in an irregular manner by means of combs. Another method is by placing the chief reflecting surface below an upper gauze surface, which being free to move causes a constant change of reflections, and produces this effect in a very pretty manner. But still another method is by electricity. The new process resolves itself practically into the local application of electrolysis. A platinum plate of suitable size is connected with the positive pole of the source of current. On this conducting surface is placed some absorbent material saturated with a solution of common salt. On this pad is placed the fabric to be water marked, and the plate engraved with the water mark connected with the negative terminal is pressed down upon it. The salt solution is decomposed, and a facsimile of the water mark is printed on the cloth. To produce opaque designs, the absorbent material is saturated with a solution of barium chloride, which is decomposed on passing the current.

The electrical pressing machine introduced by Schreihage may also be mentioned. By its employment it is possible to hot-press any description of fabric for any duration of time, at any required temperature, and all this in an apparatus which is perfectly clean and dry, and in an atmosphere free from superfluous waste heat and steam. An ordinary press is used, and may be operated hydraulically or by any other method. The press is identical with those in ordinary use. Press boards are provided, composed of suitable insulating material, inside which are embedded the heating wires. The ends of these wires terminate in a double plugway in front of each plate. The switchboard is mounted on wheels for convenience. It can thus be utilised for any press, or can be wheeled into a corner out of the way when not required. The fabric is placed in the press in the ordinary manner, and the current switched on. The plates become warm almost immediately, and when the current is switched off are soon cool enough to handle. The cost of the process is, I understand, not more than the present method of pressing when everything is taken into consideration.

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny

Editorial, Publishing and Printing Offices,

2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to THE EDITOR.

All letters for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 0d.	16s. 6d.	8s. 0d.	

New Volumes of "THE ELECTRICIAN" *commence in April and October.*

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of THE ELECTRICIAN" *Printing and Publishing Company, Limited. The well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. ELTON YOUNG, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. FISHER and J. C. H. DARBY. Price 6s. net; abroad, 6s. 9d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. PHILLIPS. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints" on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. FISHER. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. RAPHAEL. Price 5s., post free.

MOTIVE POWER AND GEARING. By H. TREMLETT CARTER. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d.; post free 13s. Vol. II. Price 12s. 6d.; post free, 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. New Edition. 93 original illustrations, price 6s.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. New edition. Price 10s. 6d., post free; abroad 11s.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d. post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d.; post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free 2s. 3d. each; strong cloth 2s. 6d., post free 2s. 9d. each. Single Primers 2d., post free 2½d.

WIRELESS TELEGRAPHY: SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES. By Dr. O. J. LODGE. New Edition. Price 5s. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, ELECTRIC TRACTION, TELEGRAPHS, TELEPHONES, &c. A. C. CURTIS-HAYWARD, B.A. To January, 1900. Price 3s. 6d., post free.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By FRANCIS JEHL. Price 10s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

THE ELECTRIC ARC.—By Mrs. AYRTON. This work is in the press and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. WADE. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. RAPHAEL. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

THE TELEPHONE.—By DANE SINCLAIR and F. C. RAPHAEL.

SPECIAL NOTICES.

NOW READY.—Vol. XLIV. of "THE ELECTRICIAN" (960 pages) bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of "THE ELECTRICIAN" (1878-1900) can now be supplied. These sets are very scarce, and early application should be made

STATE MONOPOLIES.

Following upon Mr. HENNIKER-HEATON'S four-column indictment, an anonymous correspondent of *The Times* last week declared that "the greatest living English economist" had been heard to say that the POST OFFICE ought, in the public interest, to be deprived of its statutory monopoly. Whether the present LORD FARRER answers to this description is more than we can say; apparently he thinks he does, for in a letter published in the same paper last Monday he assumes the leadership of a crusade against that monopoly on purely economic grounds, and recommends its suspension for an experimental period of (say) four years, predicting that the result would prove beneficial both financially and commercially. Great as was LORD FARRER'S authority in matters commercial and financial, we do not think that his son's reputation will be increased by this presentation of the case against the POSTMASTER-GENERAL'S monopoly. It is indeed so feeble and inconsequential that we suspect that the real mainspring of attack is a doctrinaire objection to all monopolies whatsoever; and it is on this account that Lord FARRER'S attitude, which is sure to find many imitators, may do serious mischief. Post Office monopolies are not the only monopolies in which the State as a whole is deeply concerned. Similar privileges have been granted or are being acquired by municipalities all over the country in respect of electric lighting, electric supply, electric traction, and, in a qualified form, also for telephony. Vast sums of public money are being sunk in these enterprises with the implicit, though not perhaps explicit understanding, and in the confident expectation, that they will be allowed to run their course as virtual monopolies free from risk of non-municipal competition. Should Lord FARRER'S doctrine gain acceptance in political as well as in economic quarters these expectations will be rudely disappointed, further developments in those directions will be appreciably checked, and the money already invested rendered dangerously insecure. The Post Office might survive the application of an experiment prescribed by these economic purists, but assuredly the municipalities could not.

Our readers need not be told that we are not warmly enamoured of municipal trading, but we should strongly protest against its being treated unfairly; and for this reason we greatly deprecate the attacks now being made against the very principle on which alone this line of business can

Digitized by Google

be made successful. Our view is, that, with free competition, municipal trading is, to use a homely phrase, "out of it"; if, therefore, municipal trading we must have, the municipality must be protected against unrestricted competition—at all events so long as it does its work to the satisfaction of its constituents. In this relation it may be noticed that Lord FARRER does not base his recommendation on the alleged shortcomings or incompetency of the Post Office; he seems merely to have taken advantage of the heedless outcry against that department during the past few weeks to air in public his secretly-cherished conviction that all monopolies are bad, and that the Post Office monopoly should be the first to go. If he were asked, he would certainly admit that it ought not to be the last. He regards as a "mere bagatelle" the possible loss of three and a-half millions of national revenue; the local taxpayers' loss under a similar infliction he would, no doubt, consider a mere fleabite. Of course, he professes not to anticipate any loss whatever; brains would be quickened on all sides, and everybody would make the same income as before. Lest this bold statement should not find credence, it is added that in any event the public service would be cheapened and improved.

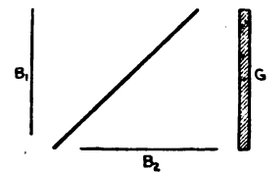
Now this assertion as to cheapening and improving is, we contend, a pure assumption. Commercial history does not bear uniform testimony even to cheapening; and it tells pretty generally against improving. The case of the telegraphs, which is very pertinent to the matter under discussion points all in favour of combination and uniformity—in other words for monopoly. Rates were vastly higher, the service greatly inferior when they were ruled by private companies; whilst the multiplication of lines not connected as a whole was a public inconvenience of the most serious kind. The same statement applies to the telephone service; and disregard of these considerations in recent years has led to the present altogether intolerable muddle, out of which there is no escape but by resort to the principle of combination and monopoly—whether under the State or in private hands is a matter of little moment. This essential element of a monopoly such as we are now considering—namely, its uniformity and universality—is utterly ignored by economic writers like Lord FARRER; and, strange to say, by *The Times* newspaper when commenting upon their propositions. The case for a State monopoly is not covered by advantages derived from remunerative areas paying for the unremunerative. It includes the supreme merit of a single administration, and of the public knowing exactly where it is, what it is, and how to use it. How great would be the inconvenience were this advantage relinquished we can faintly realise by picturing the state of things under a reversion to competitive inland telegraphy. One may argue that the telegraphs would do better in other hands than the Post Office; but no sane person in these days will deny that they must be in hands belonging to one body.

It does not follow, however, that what is good and even indispensable for the welfare of national telegraphs is good or desirable for all the other electrical concerns of which mention has been made. Circumstances differ in different localities, and different principles may be safely applied to them. All that we contend for is that, where there is a clear field and a monopoly is granted, nothing should be said or done to interfere with its growth or endanger its stability. That such interference is foreshadowed in Lord FARRER'S communication, and the support he has received, nobody can doubt; and it behoves all local authorities as well as private promoters to take whatever steps are possible for permanently safeguarding their concessions. Any direct attack upon them or any threat of it in the not distant future is sure to inflict financial loss upon the community generally; but the radical financial iconoclast will not be deterred by considerations of that kind. Perhaps the best shield against such assailants is a good character. There are two kinds of monopolies, one the monopoly of expediency, the other of merit. We agree with *The Times* that the Post Office monopoly would never have been challenged had it not exposed itself to the criticisms of its enemies. Those municipalities who carry on their business thoroughly well will have the best chance of remaining undisturbed. They have many enemies: their safety depends upon disarming them beforehand.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. FOURNIER D'ALBE.]

Temperature of a Radiating Body.—The temperature of the surface of a radiating body is usually supposed to be equal to that of the interior; but this is by no means strictly the case, especially when the body is a bad conductor and a good radiator. To determine the actual difference in a concrete case F. Kurlbaum makes an experiment, the principle of which is indicated in the annexed diagram, where P is a sheet of platinum foil 1μ thick, covered on both sides with platinum black. Light falls through the glass plate G upon the platinum, and the heated platinum sends heat rays to the bolometers B_1, B_2,



placed symmetrically with regard to the sheet. Any difference between the temperatures of the two surfaces will be indicated by a difference in the deflections of the two bolometers. As a result, the author finds a difference of temperature of 0·016deg. when the sheet is heated 1deg. above its surroundings, and 0·068deg. when the sheet is blackened with lampblack instead of platinum black. This difference is, of course, only that which applies to the special case, but anyhow it is smaller than usually supposed.

[F. KURLBAUM, *Ann. der Physik*, No. 7, 1900.]

Thermodynamics of Cells.—It is now pretty generally admitted that every current of heat produces an electric current, and vice versa. C. Liebenow attempts to account for this by assuming that the heat consists in the vibrations of the negative particles, now usually called electrons. Anything which moves these negative electrons will move the heat attached to them by convection, and so every electric current will go hand in hand with a heat current. The amount of heat can be calculated from the equation

$$9 = -0{\cdot}24\,\mathrm{T}\,i\frac{d\mathrm{E}}{d\mathrm{T}},$$

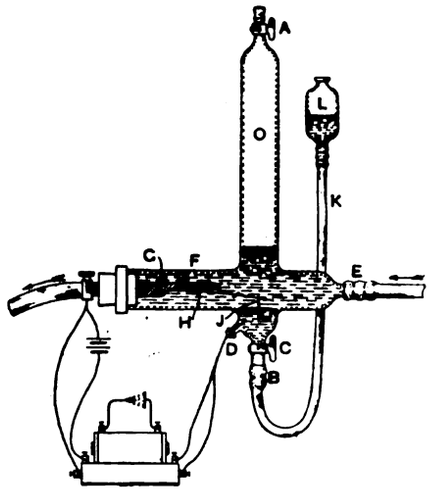
which gives the amount of heat conveyed by a current i through any cross-section of the metal in one second. For copper, the amount of heat thus supplied to each gramme-atom precipitated from solution would be 870 calories at 0deg. But since the total heat of the gramme-atom is about twice that amount, it may be said that half the total heat of the metal is conveyed by the negative electron, and the other half by the positive electron. The author further shows that all metals in the solid state are monovalent, and that the atomic heat of negative and positive electrons is $870/273 = 3{\cdot}2$, or about the same as the atomic heat of monatomic gases at constant volume.

[C. LIEBENOW, *Ann. der Physik*. No. 7, 1900.]

New Mercury Interrupter.—E. Grimsehl has designed a mercury interrupter on a novel and ingenious principle, for which he claims that it absorbs little energy and mercury,

Digitized by Google

costs little, and is efficient on circuits provided with a low supply of power. The interruptions are produced by the reed of an organ pipe "blown" by a current of water, which serves the additional purpose of keeping the mercury clean and cool. The construction is shown in the diagram, where G is the organ pipe, H the reed, J a plantinum tip attached to it, O a cushion of air which serves to impart the necessary elasticity to the water, and E the tube through which the water flows in. The level of the mercury is regulated by the tap C and the reservoir L, connected to it by the flexible tube K. Interruption is very abrupt, owing to the high resistance of the water, and the rate of interruption is of course much steadier than in the Wehnelt interrupter, but on the other hand it cannot be brought much higher than 100



per second. Any mercury carried off by the water can be collected in a wash bottle inserted in the water current. The platinum point shows very little wear, owing to the cooling effect of the water.

[E. GRIMSEHL, *Elektrotechn. Zeitschr.*, June 14, 1900.]

Spectrum of Radium.—Among the radio-active substances discovered since Becquerel's description of the peculiar properties of uranium rays, radium has proved to be the most interesting. It is capable of sending out both cathode rays and Röntgen rays without being electrically excited. It emits these rays in great intensity, comparatively speaking, and with an apparently unlimited supply of energy. We know now that even if the energy of the body is being spent and diminished in the process, such diminution would not become apparent for a number of years, and this consideration saves the law of the conservation of energy in our estimation. But the mode of excitation of radium is as yet unknown, nor has the metal itself been as yet isolated, although it has been obtained as a chloride. This might produce suspicions as to its elementary character were it not for the almost conclusive evidence of the spectroscope. Some time ago (see *The Electrician*, Vol. XLIV., p. 140) E. Demarçay identified certain spectrum lines with radium, and he now produces further evidence for the identity then established. In addition to the strong and bright lines of wave-lengths 3,815, 4,341, and 4,683, he noticed a band at 4,627 and another at 4,455. This brings the spectrum into close analogy with the spectra of the metals of the alkaline earths. It would be interesting to determine how the spectrum rules discovered by Kayser and Runge are obeyed by these new lines.

[E. DEMARCAY, *Comptes Rendus*, July 23, 1900.]

Thermodynamics of a Voltaic Cell.—The theory, commonly known as Thomson's, that the electrical energy of a reversible voltaic cell is the equivalent of the chemical energy transformed, has been abandoned as an exact expression of the facts since the appearance of Helmholtz's Paper on "The Thermodynamics of Chemical Processes," in 1882, and Jahn's experimental corroboration. Some of the chemical energy may appear as heat direct, as in the Clark cell, which has a negative temperature coefficient. Helmholtz's calomel cell, which has a positive temperature coefficient, absorbs heat and cools down in generating a current. In Daniell's cell, on the other hand, there is a strict equivalence between the electrical energy evolved and the difference between the heat of combination of the zinc sulphate formed and the copper sulphate decomposed. H. S. Carhart has studied this process in detail, and has for this purpose treated the positive and negative sides of a cell separately. He shows that the most important determining quantity—the temperature coefficient of the E.M.F. of the cell—is made up of the sum

$$\left(\frac{dE}{dT}\right)_p + \left(\frac{dE}{dT}\right)_n$$

at the positive and negative poles respectively. These are the Peltier effects at the junction between each electrode and its liquid. In practice the quantitative values obtained are complicated by changes of concentration, which, however, the author has succeeded in eliminating.

[H. S. CARHART, *Phys. Review*, July, 1900.]

ELECTRICITY WORKS ACCOUNTS.

Liverpool Overhead Railway.

A comparison of the figures in our analysis of the accounts of the Liverpool Overhead Railway for the two half-years ended June 30, 1899 and 1900 shows that in spite of the much higher price of coal the working expenditure per train mile in the latter half-year was practically 1d. under what it was during the corresponding period in 1899. This, and the fact that the fuel charge itself was reduced, is explained by the existence of a very advantageous contract to the company for the supply of coal. The expiry of this contract entails a payment of nearly double the old price of coal so that there is cause to fear a decided increase in the expenditure during the current half-year.

The train mileage run showed an increase of a little over 7 per cent.—the figures including the traffic on the tramways, or car mileage—and as the number of pasengers carried increased only by 4·75 per cent., the receipts per train mile show a diminution, although not to the same extent that the costs have.

We heartily congratulate the company upon their increased dividend, and also, as we learn from the chairman's report, upon the splendid punctuality of the train service—97·3 per cent. of their trains having, during the past half-year, been up to time, thus maintaining the company's record in this respect.

It is satisfactory to learn that the lighting of the trains is engaging the attention of the management, and that the batteries for the improvement of the lighting are nearly completed. A new train for accelerating the traffic by 15 minutes is also nearing completion, and we understand that the distance of 6½ miles with 15 stoppages will be covered in 20 minutes. A mineral traffic over the line during night time is under consideration.

The following table furnishes particulars of the traffic over the line and the dividends distributed since the opening:—

Half-year ended	Passengers.	Train mileage.	Per cent. dividend

City and South London Railway.

Increased working expenses and diminished receipts per train mile on this railway were to be expected with the opening of the extensions to Moorgate-street and Clapham Common and until these extensions had had time to develop their traffic. It is very satisfactory, however, to learn from the directors' report that since the opening of the above portions of the system, on Feb. 26 and June 4 respectively, the receipts have been steadily improving.

Looking down the costs column attention is arrested at the increase in the traffic expenses, amounting to more than 1d. per train mile. Other items which have naturally increased are those of coal and oil and stores. These together account for an increase of nearly 0·5d. per train mile. All the other important items of expenditure have been reduced, with

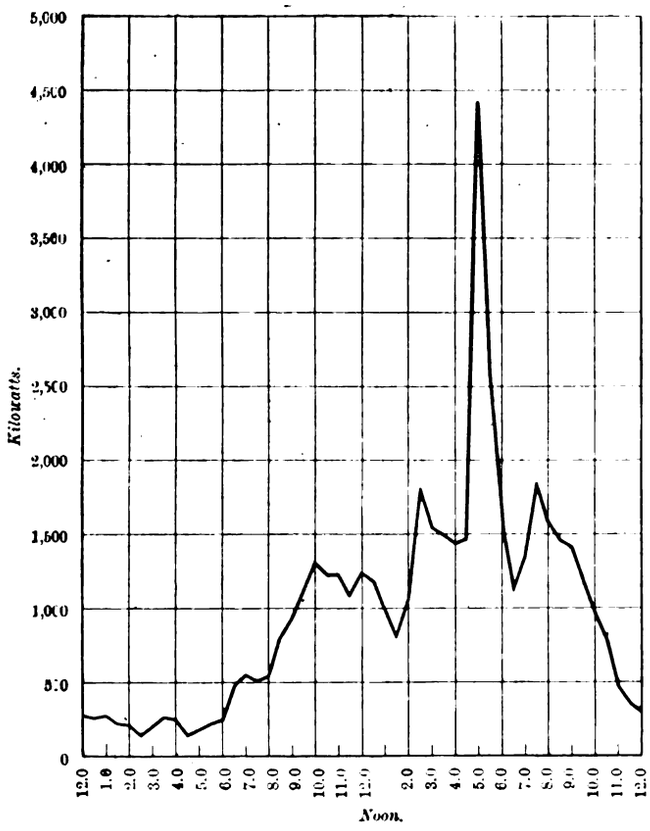
AN ABNORMAL LIGHTING LOAD CURVE AT MANCHESTER.

Through the courtesy of Mr. C. H. Wordingham, the Corporation Electrical Engineer at Manchester, we are



Load Curve at Dickinson Street Generating Station.

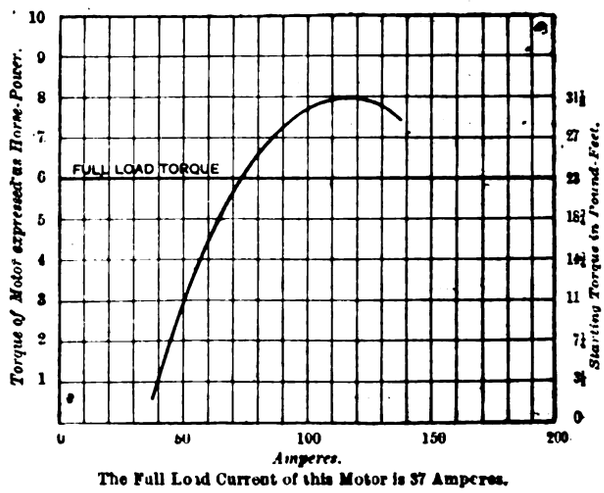
enabled to publish the accompanying diagram showing a lighting load curve possessing unusual features of interest. The curve is for the Corporation electricity supply works at Manchester, for Tuesday, August 21. On that day Manchester was visited by a very heavy thunderstorm, which occurred between 4.30 and 6 o'clock p.m., causing, as will be seen, a sudden and heavy demand on the generating plant and batteries. It may be questioned whether a more severe tax on the electric generating plant in a supply station has ever been imposed even by a metropolitan fog.

ALTERNATING-CURRENT INDUCTION MOTORS.*

BY A. C. EBORALL.

(*Concluded from page 679*).

Performance.—The Heyland motors standardised for circuits of 40, 50, and 60 cycles are designed in three ways, as follows :—(*a*) To start without load. Under these circumstances the starting current does not exceed four-fifths of the full-load running current. (*b*) To start with two-thirds of the full-load torque. Under these circumstances the starting current does not exceed one and a-half

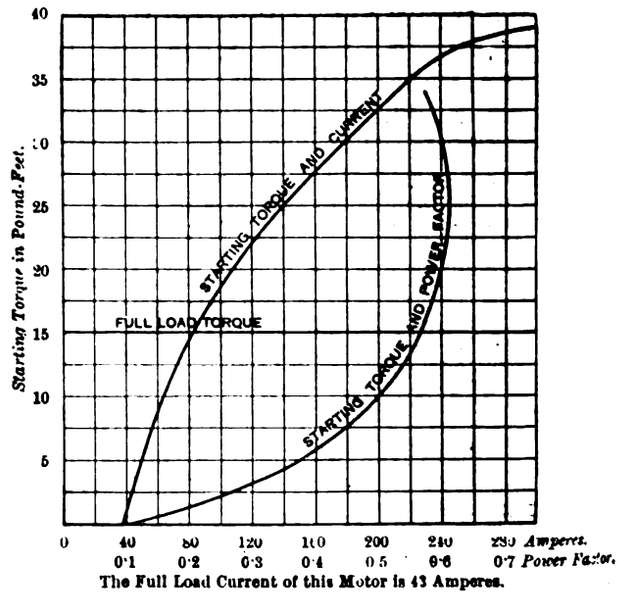


The Full Load Current of this Motor is 37 Amperes.

FIG. 11.

times the full-load running current. (*c*) To start with full-load torque. Under these circumstances the starting current does not exceed twice the full-load running current.

Design (*a*) has been evolved in order to conform to the ideas of many station engineers in this country. Design (*c*) represents the normal winding, while design (*b*) is frequently asked for. The



The Full Load Current of this Motor is 43 Amperes.

FIG. 12.

starting torque with the standard stampings is determined purely by the number of turns of the starting coils and the permissible current ; this torque can be arranged to have a value equal to two or three times the full-load running torque, if enough current is given to the starting coils, the limiting value occurring at the saturation point of the iron. Fig. 11 and Fig. 12 illustrate the starting

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

performance of two motors designed to fulfil conditions (b) and (c) respectively, while Fig. 13 illustrates the running performance of the motor, whose starting curve is given by Fig. 11. All these curves represent the results of actual brake tests, and many motors built have given better results than indicated here. Particular attention is given in all the designs to the overload capacity of the motor, and all motors are guaranteed to stand a 25 per cent. overload for one hour. The small overload capacity (varying from 0 per cent. to 10 per cent.) found with the alternating-current motors hitherto used*, has been one of their worst features, as for most work it is impossible to fix the amount of power required so exactly as this, with the result that the motors installed are invariably too large and costly for the work they have to do. This reacts on consumer and supply company alike: the former has to pay for a larger motor than he wants, which will be working on the average at low efficiency, while the latter most of the time is supplying an underloaded motor having a low power factor.

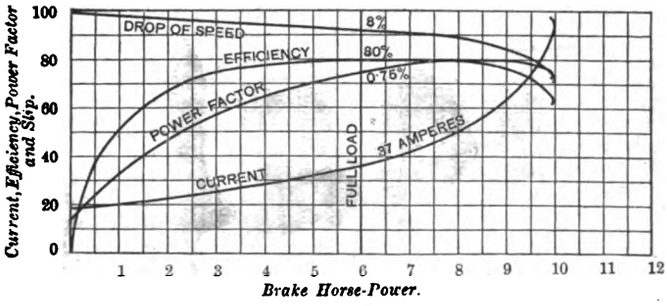


FIG. 13.

The results obtained with the Heyland motors for circuits of 80 cycles and 100 cycles are not quite so good as those given above, with regard to starting torque. That is to say, these high-frequency motors as built up to the present take a relatively greater current for a given value of starting torque, the values being—(a) when starting without load current is equal to the full-load current; (b) starting with half the full-load torque the current is one and a-half times the full-load current; (c) starting with full-load torque the current consumption is two and a-half to three times the full-load current. The increased values of current consumption are, of course, due to the larger number of poles necessary to bring the speed to a reasonable figure; particularly in small motors the number of poles has a very great effect on the amount of magnetic leakage with a given design. As, however, the Heyland motors are not yet fully standardised for 80 cycles and 100 cycles, the designers hope to effect considerable improvements within the next few months in the direction of reducing the current for a given value of starting torque.

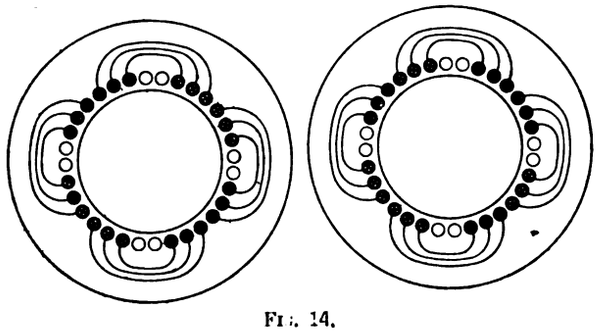

FIG. 14.

Before leaving the subject of these motors, the author would like to draw attention to an exceedingly neat method Mr. Heyland has devised for regulating the speed of induction motors, single and polyphase. As is well known, there are two principal ways of altering the speed of such motors, the supply frequency being constant * The first is by rheostatic control, a non-inductive regulating resistance being in circuit with the rotor windings, while the stator windings are connected directly to the mains; the second is by altering the number of stator poles by means of a suitable controller, together with those of the rotor, unless the latter is of the "squirrel-cage" type. Here the motor is wound for the maximum number of poles, and when it becomes necessary to pass from a greater to a less pole number, in order to get increased speed, the windings on some of the poles are reversed, thus producing fewer poles, which are in consequence much broader. For instance, in order to double the speed, half the poles have their windings reversed, the stator having now half the number of poles, each of double the former breadth. While rheostatic control is simple and easy to use, it has the great objection of being very uneconomical. The waste of energy brought about by its use is entirely analogous to that found with shunt-wound direct-current motors, with constant field excitation and a regulating resistance in the armature. The case of the induction motor is really more unfavourable, because it has been found by experience that the motor has to be rated very liberally in order to get the necessary power. On the other hand,

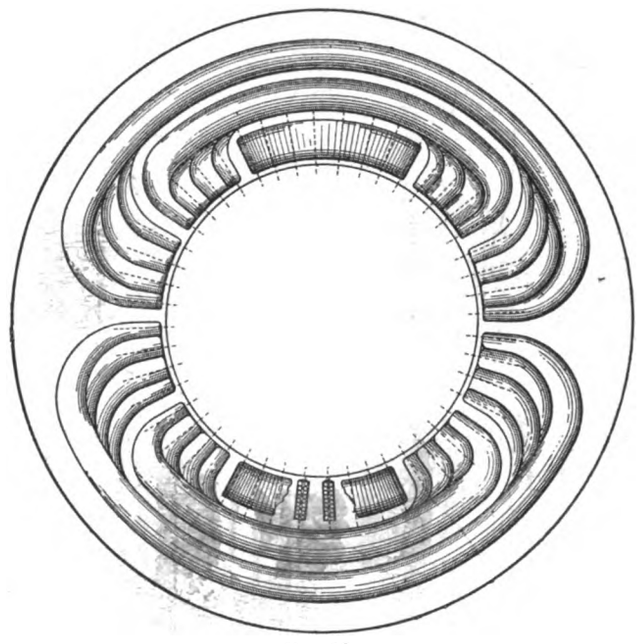

FIG. 18.

the method of altering the number of motor poles has two serious disadvantages. Firstly, the reduction of the number of poles causes an unfavourable distribution of the magnetic flux, a large increase of magnetic leakage and a loss of winding space. This is of course owing to the fact that after the reversal of the appropriate coils the currents flowing down one side of these coils are neutralised by the currents in the adjacent side of the unreversed coils, as will be readily seen from Fig. 14, illustrating the single-phase case. Secondly, unless the motor has a squirrel-cage rotor, the rotor circuits become very complicated; the polarity of the rotor

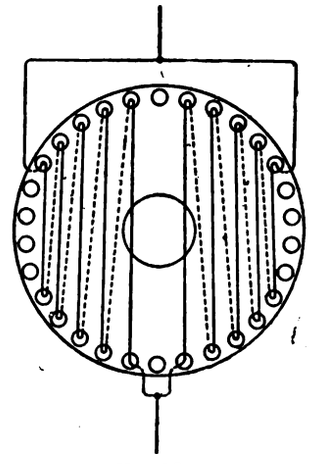

FIG. 19.

windings has to be changed each time in accordance with the stator polarity, which means that a large number of slip-rings have to be used in order that this may be done. Mr. Heyland's method consists of certain winding arrangements, which, when it is desired to change the number of poles, render any reversal of the rotor windings superfluous, and to a large extent obviate the drawbacks stated above in the reversal of the stator coils. The method of winding the stator, as applied to single-phase motors, is illustrated in Figs. 15, 16, 17, and 18, the last figure showing how the stator coils are wound in practice. In all cases the winding is carried out for the smaller number of poles, and divided into sections, one or more of

* The author would here like to make an exception in favour of the Wenström motor, whose overload capacity (as found with examples tested by him) is everything that can be desired.

* The method of "tandem parallel control" for two motors, while excellent theoretically, is hardly likely to come into commercial use at present, on account of the great complication involved, and because of the bad conditions under which the motors have to work.

Digitized by Google

these sections being reversed to obtain a greater number of poles. Thus, for instance, in Fig. 15, the stator being wound initially for two poles, by reversing one of the sections of the winding a four-pole stator results, as indicated, and it will be seen at a glance that there is no neutralising action between adjacent conductors, and that the distribution of magnetic flux in the air-gap will be perfectly goo d.

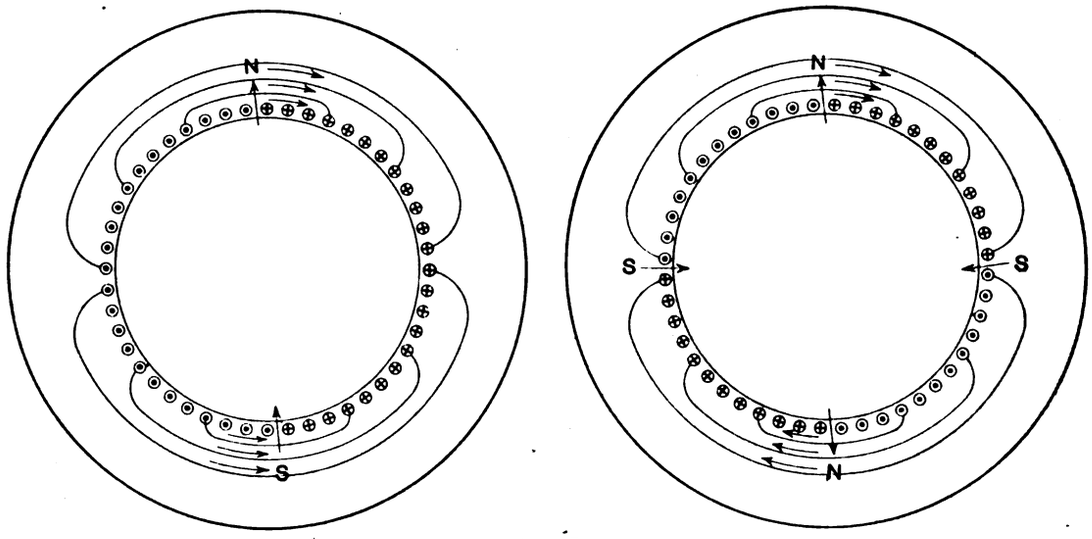

Fig. 15.

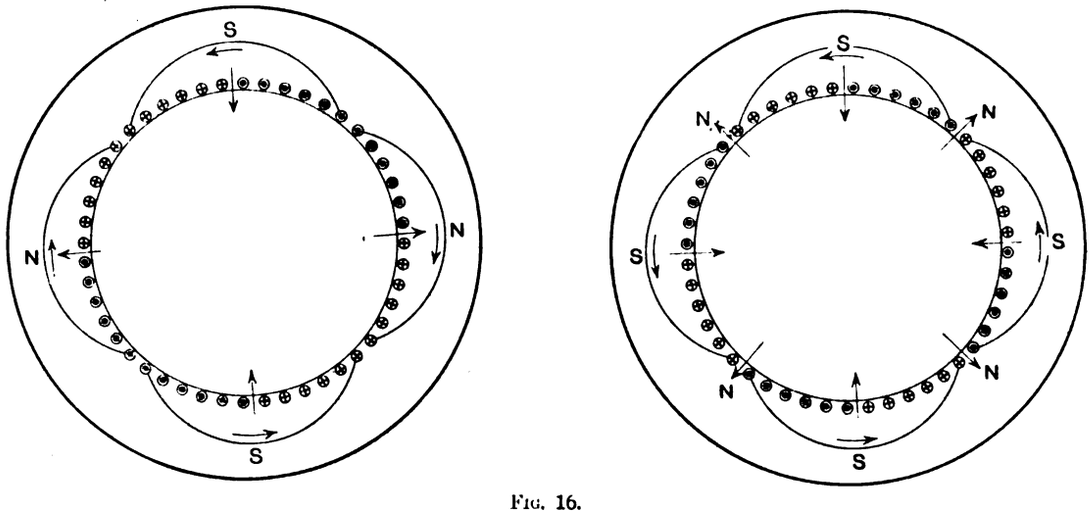

Fig. 16.

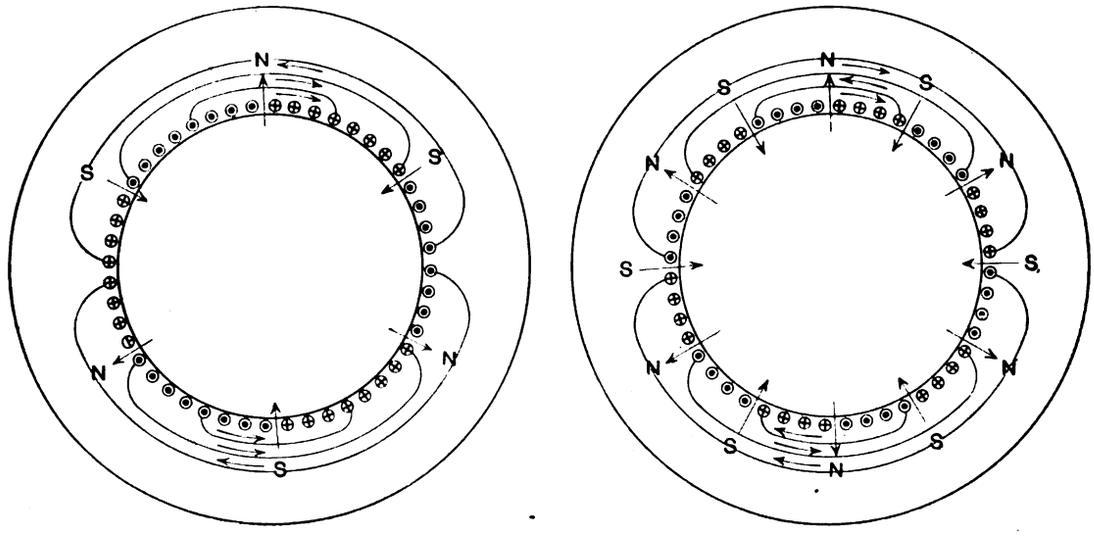

Fig. 17.

Fig. 16 shows the arrangement for a four-pole to eight-pole stator, and Fig. 17 that for a six-pole to twelve-pole, to which the same remarks apply. The manner of carrying out the stator winding for the last case actually employed is illustrated in Fig. 18.

For polyphase motors, exactly the same winding arrangements are used, applied of course to each phase. For these motors, if more than one change of speed is desired, the controllers get somewhat expensive, and it is therefore better on the whole in such cases to combine the method with rheostatic (rotor) control, the rheostat being used for the intermediate speeds only. For small motors having squirrel-cage rotors, no modification of the rotor winding is needed; but where wound rotors are employed the general method of rotor winding is illustrated in Fig. 19, which illustrates the single-phase case for simplicity. The general principle is to so arrange the windings of each phase that they are formed of a number of sections in parallel; with a certain number of poles the E.M.F. of one section will neutralise that of another section in parallel to it, and a current will flow through the sections only when they are externally short-

Digitized by Google

circuited; on the other hand, with double the number of poles, the external short-circuit is superfluous. Thus consider Fig. 19, representing (diagrammatically) the winding for one phase of the rotor for a two-pole—four-pole stator. Each phase has two sections, permanently short-circuited one on the other. At starting the stator switch is put over to the two-pole position, and the slip-rings gradually closed through the starting resistance. So long as the slip-rings are open, no currents flow in the rotor windings, as the induced E.M.F. has the same value in each section, and the two E.M.F.'s neutralise one another, on account of the two stator poles. But the rotor currents circulate as soon as the rings are connected through the resistance—this latter is gradually cut out in the usual way as the motor comes up to speed. In changing over now to the four-pole position (if the higher speed is required) the slip-rings are not wanted, as the two sections are now in series, with the E.M.F. in the same direction, and so the rotor currents can circulate independently of the external short-circuit. The same general arrangement is used for motors to run at more than two speeds. Here the rotor windings (per phase) can have more than two sections, these sections being wound partly to overlap one another, while still being in parallel, so that the various E.M.F.s partly neutralise one another and partly add themselves together. With this arrangement, the same rotor winding can be effectively used with a stator having several different arrangements of the poles—that is, for a motor running at several distinct speeds. For induction motors having rotors with star-connected three-phase windings, which is the practical case, only three slip-rings are required, the (second) common junction being at the three slip-rings, as usual.

In the workshops of the author's firm, where many of the tools are driven by three-phase motors, the Heyland method of speed regulation is employed with great convenience. Several of the larger tools (such as planing machines and the like) are driven by independent three-phase motors wound for two speeds, the alteration of speed being effected by throwing over the reversing switch. It has been found by tests on these motors that the power-factor is diminished very little by the increase in the number of poles, attaining a high value at both speeds, while the efficiency is also high at each, there being but slight loss of energy involved by the change-over. At the same time, the increase of first cost with the two-speed motors is very small.

Concluding Remarks.

Although the author has dwelt at some length upon the subject of single-phase motors, it has been more on account of the technical interest attached to it than because of any belief in the present or future possibilities of single-phase systems. Regarding the Continent and the States it is not too much to say that single-phase supply is practically played out, and that engineers responsible for putting down new stations for either power or lighting consider single phase supply systems out of date and their employment bad practice. Moreover, indications are not wanting that the present tendency in this country is to follow in the same direction. It is certain that for all those cases where continuous-current systems are out of the question every requirement can be far more successfully met by three-phase systems than by any other. It is true that certain engineers in this country hold the opinion that pressure regulation troubles are bound to occur with three-phase working (an opinion not shared by the author), but, even supposing this to be the case, the complete solution is to hand—convert to continuous current by means of rotaries, or better, by means of motor-generators. The standardisation of the above two systems, together with that of two voltages for each system—220 volts and 440 volts—and one frequency—50 cycles—for the supply net-works is greatly to be desired, particularly from the point of view of the motor manufacturer and the motor user. With the hope that this ideal may be eventually realised, this Paper can be concluded.

IMPRESSIONS OF AMERICAN TRAMWAY PRACTICE.*

BY A. E. LE ROSSIGNOL.
(Corporation Tramways Engineer, Newcastle-upon-Tyne)

When I was asked to read a Paper I thought that, having paid a visit to the United States this year, some account of my impressions of the present state of tramway engineering practice in that country might be interesting to the members of this Association. The conditions governing tramway practice in America are essentially different from those prevailing in this country: on that side of the Atlantic the tramway concessions are almost without exception in the hands of companies who in very many cases have been granted them in perpetuity, and some cases at merely nominal rents, so that now the value of these concessions is very great. In addition, the process for obtaining leave to extend is very much simpler and quicker: there are practically no limitations set by law to any combinations or absorbtions the companies may choose to make with other companies, the speed of running is very great, and the doctrine that might is right holds to an extent we would not tolerate here. Contrast these with the conditions prevailing on this side of the water. In Great Britain concessions for tramway construction take a long time to carry through and are difficult to obtain; combinations or absorptions are jealously watched and difficult to bring about, and companies and corporations are very much hampered therefore in developing their tramway systems to anything like the scale which American tramway undertakings attain if successful, while the maximum speed allowed is so low that competition with railways is out of the question. Again, owing to the inherent conservatism and venerable age of British institutions, the delimitations of local authorities are very much more circumscribed and divided up than in America, so that extensions which involve trenching on the ground under the control of different and distinct local authorities involve much more difficulty in obtaining leave for extension, both to companies and to municipal authorities who may wish to extend a tramway system owned by them.

Need we wonder, then, at the great extent reached by some of the tramway systems in America; systems formed by the gradual acquisition by one master company of all the competing lines in any one city or district, till at last all the lines are under one control, and competition is entirely done away with. As you may have noticed, a typical instance of this spirit of absorption has just been completed in New York. Prior to this year there were two tramway companies in New York, the Metropolitan—which had gradually absorbed all the smaller companies, with the exception of one—and the Third Avenue Company—which owned two lines running from the heart of the city out to the Haarlem River, and beyond that owned a large extent of country lines. Early this year the Third Avenue Company got into financial difficulties over the provision of new capital to meet the heavy expenditure it incurred in converting the cable system into an underground conduit system, and the Metropolitan Company stepped into the breach, provided the capital required, and thus obtained control of the last opposition company left in New York. Latterly the American tramway world has become greatly exercised over the question of municipal ownership, the municipalities, who originally granted free wayleaves, and in some cases ground rights on the streets as well, to the tramway companies, in order to get them to run lines out into the country and create new populated districts, now find that these rights and privileges granted by them are becoming very valuable, and are seeking either to get hold of the tramways again or else to make the companies reduce the fares or pay higher percentages of their receipts to the municipal authorities. The companies are therefore deprecating in the Press municipal ownership, and as an argument in their favour compare the extent of the largest tramway system in a town in the States of a similar size, greatly to the advantage of the latter of course. In their comparisons, however, such reasons as I have given in the first part of this Paper are entirely overlooked, but there is no doubt that municipal ownership in the United States, under the conditions prevalent at present in municipal circles on that side, would give rise to a great deal of bribery and corruption, until in course of time a better moral condition of municipal life comes to the front. At the time the combination took place between the Metropolitan Traction Co. and the Third Avenue Company in New York, the former had very nearly finished a very large power station, from which they were already supplying the lines they had converted to electric traction, and the Third Avenue Company were only laying the foundations of a still larger power station, so that the amalgamation has in this case come at a suitable time when the question of the provision of the requisite amount of power for the combined system will not be complicated by the existence of too many power stations. In most previous amalgamations of this kind in the States—of which Philadelphia is a typical example—the combined company has left on its hands a multitude of small power stations, each of which have been owned by one or other of the smaller companies it has absorbed.

Due to the fact that conversion to electric traction was just in progress, the combined company in New York is now in a very favourable position to extend its large system in the best and most economical way, and the present tendency—one might almost say the fashion—in tramway construction in America, leans towards the erection of a large central station with high pressure distribution to sub-stations. Those companies which are hampered with a number of low-tension power stations do not, however, admit that their economical results are very greatly, if at all, inferior to those attained as yet by the larger single systems, and are in many cases providing for additional extensions by adopting battery sub-stations with charging mains to those fed for boosters. By the almost universal adoption of coal handling and storing machinery too, the fuel costs of stations in America are kept remarkably low; as they are all owned by private companies, however, a strict reticence as to these

* Paper read before the Municipal Electrical Association, at Leeds, June 23rd.

Digitized by Google

costs is maintained, in complete contrast to the practice on this side of the water where we are accustomed to publish full details of all working costs.

As economy in current generation is greatly influenced by the expenditure on labour in the station, central station practice in America rightly tends to the introduction of very large steam power units, but these are all of the open slow-moving type, and so require a larger amount of attendance than would the same size units, if enclosed and provided with automatic lubrication, such as have been largely adopted in this country. A system of mechanical oil supply to these large open engines has been adopted; but if the enclosed type were made as strong in proportion and as reliable in operation as the large open type, there is no doubt that increased economy in labour would be obtained, and doubtless English manufacturers will awaken to this fact in a short time. Due to the heavy strains encountered in direct-current traction work, American steam units have gradually grown to huge proportions of the strain bearing part, the shaft, and even though the strains probable in alternate current work will be very much less, the same proportioned engines are being installed in the three-phase plants. Owing to the adoption of large steam units the question of provision of adequate boiler power in a reasonable amount of floor space to correspond with the engine floor space has been met by the adoption of two or more boiler floors one above the other, surmounted by huge coal bunkers at the top, and exemplify the trust placed by American engineers in steel-framed buildings.

The question of control of the large amount of electric power generated by the large units is now being taken into adequate consideration; up to the present switchboards have always been strongly suggestive of the instrument making days, but in the new power station of the Metropolitan Traction Co. the switches are built on engineering lines of generous proportions, and are worked by pneumatic power and controlled electrically. Three large galleries at one end of the engine house are given up entirely to the switches, each in a brick cell of its own, while the actual controlling boards take up very little space.

Underground open conduits seem to work very successfully, but have only been introduced in two cities, New York, and Washington, in both of which towns no sanction for overhead wires could be obtained, and the companies had to face the heavy costs of underground conduit construction. In both towns the companies were greatly assisted in the expense by having to convert a large extent of cable traction into underground conduit, a change that is and has been carried out without much interruption of the service. Two conductors are always used and means provided for changing these conductors on to either positive or negative bars so as to enable traffic to be kept running, even with one conductor grounded in any or every section.

Transformers are mostly of the air-blast cooled type, and have the low-tension side directly connected, without switches, to their rotarys. These latter apparently work very well, and do not give any trouble with overloading, providing no over-compounding is attempted. Compounding for a level voltage is provided for by the introduction of self-indication in the high-tension feeders and a series winding on the direct current of the rotary. Return-current automatic cut-outs on the high-tension feeders have been installed at sub-stations, but up to the present do not seem to be very reliable in their working.

In no case, so far as I am aware, are return current boosters used, the current having always to find its way back to the station by the rails and supplementary cables, so that even with good bonding the maximum fall of voltage from one end of a line to the station is sometimes very great. There is no limit fixed by law, and the only limit the companies recognise is an economic one when too much pressure is lost in the return circuit. A good deal of electric welding and cast welding of the rail joints has been done, and the last is looked upon, I think, with more favour; no bonds are used with this method of jointing, but if used in this country, with the Board of Trade limiting the total fall of potential to 7 volts, bonds would certainly have to be provided.

Overhead work in America does not compare at all with what is put up in this country, either as to strength or neatness, but in many other traction matters we have something to learn from our American cousins, especially from the way they have realised the great part electric traction plays in making adequate provision for the population of large cities, enabling poor people to live at a greater distance from their work and in better surroundings than is otherwise the case. In conclusion, I would like to express my thanks for the kind hospitality dealt out to me by all the engineers I met during my visit.

DISCUSSION.

Mr. C. H. WORDINGHAM (Manchester) noted that one of the principal features of the author's Paper was the advocacy of large schemes, and his conviction that in time the whole of the supply in a district will be in the hands of one authority for supplying light and power to large towns. This was very reassuring to him (Mr. Wordingham) as it was what he had advocated for Manchester. He would like to have Mr. Rossignol's opinion as to the use of motor generators and rotary converters for all the purposes to which these will be put. He would also be glad to hear his opinion as the relative advantages of the two and three-phase systems of distribution. He would like also to know more about the fuses mentioned—as to how they were arranged, the space occupied, &c. He referred to putting ways beneath the tramways into which cables could be drawn afterwards. He did not know whether there was any difference in America from here, but he had come to the conclusion that the surest way to ruin a cable was to pull it into a pipe. He thought all drawing-in systems would have to be given up as they were fatal to the cable.

Mr. S. Z. de FERRANTI (Hollinwood) said the Paper was one which he found exceedingly interesting. He had not had the advantage of going over to the States but he had many friends there. The special station called attention to in the Paper was that of the Metropolitan Company of New York, it was certainly a most magnificent station and everything was carried out on a large scale. So far as one could judge from reading the descriptions everything had been thoroughly provided and put into the best possible form for achieving the result they desired to obtain. There was one thing about the switch gear which the author had not mentioned. To show that they did not place too much reliance upon the gear he might say that all the important switches were placed two in series; there were two sets of switch gear separately controlled and connected with the generators. With regard to large schemes for supplying electricity they would be aware that no one had advocated this more than he had: it had been one of his pet ideas all along. The difficulty was that they involved such a large amount of transformation and controlling apparatus. The capital expenditure did not go down in these big schemes as one would like to see it. He had been conversing with Mr. Short, who had been the chief engineer of the Walker Company in America, and he informed him that they got the option of a number of sites in New York City for generating stations. They went into the matter at great length and he (Mr. Short) assured him that to have several stations came out at a less price as regards capital expenditure, and as regards running, than this great station which has been erected by this company in America. There was a point of particular interest in the Paper upon generating machinery. The author states that they use the open type engines and build them in good style, but these take more attention than the enclosed engines commonly in use in this country. The suggestion given was a good one, viz., to combine the advantages of the large open type engine with what they knew of the enclosed engines here. If they could only get plant which had both these advantages he was sure they would be able to go one ahead of America.

COUNCILLOR BERT (Glasgow) had a little experience some years ago in the States; they were then in favour of the cable system. He thought the Americans had great advantages; they started out with a clear field and had not any prejudices.

Mr. E. TREMLETT CARTER was reminded of a tour he made in the United States some time ago. When at Washington he saw there the conduit system, and he thought it worked excellently, his impression at the time being that as soon as the conduit system was a little more developed in the mechanical part of the construction it would be a good system for our own cities. He considered it was a great pity that our large cities would not expend a little more capital and use the conduit system. Since that time the conduit system had been greatly improved and was extensively used in New York; in fact, it was so perfect now that it might be used with advantage in congested streets working the trolley system for outlying districts. It was surprising to see in America how large stations kept an even load; being very different from the experience over here, where you can tell often when a car is going up a hill. As to instruments, it was common to see an automatic cutout propped up with logs.

Mr. A. G. COOPER (Colne) considered that the samples of American engines he had seen in this country did not come up to those manufactured over here. He found in one of the large stations in this country the governor was run by a small belt, and he thought the English makers could give the Americans a point there.

Mr. J. K. BRYDGES (Eastbourne) stated that he had lived eight years in America and had had something to do with railway practice. The overhead work in America was very poor compared with the work in this country. Many of these overhead tramways were erected with a view of helping the surrounding country.

Mr. A. E. LE ROSSIGNOL (Newcastle-upon-Tyne), in his reply, stated that it was really astounding to see how the small amount of capital expended in running these tramways developed the surrounding country and made it practically a part of the town. If only some alteration could be made on this side to get over the difficulties caused by different districts belonging to different local authorities so that one company or one corporation might own the tramways and run them into the country districts, then the working classes would be able to live in more salubrious surroundings than at present. He did not think any town would benefit more than Glasgow in this respect when their tramways reached all the districts around, as the population was very dense in the central portion of the city. With reference to rotary converters, what he saw in New York and Niagara the chief towns where these were employed, were working satisfactory. There seemed very little difficulty providing they were large enough and the fluctuations were not very great. He said it was quite true that the Metropolitan Company of New York had two switches in series on the large generators, but even assuming they were rather expensive he did not think they were out of proportion to what were used here with smaller units and a larger number of switches. The trouble in America was to find suitable sites at a reasonable price for erecting works. It was possible to find one or two sites where you could put down a large three-phase generating station, but you could not as a rule find half a dozen sites where you could put down large stations with the advantages of condensing water, &c,

A MODIFICATION OF MANCE'S METHOD OF DETERMINING BATTERY RESISTANCE.*

BY LOUIS W. AUSTIN.

One of the most elegant methods of determining the resistance of a battery cell is undoubtedly the Wheatsone's bridge method of Mance. As ordinarily used, however, it labours under certain disadvantages. Leaving out of account the annoyance of adjusting the galvanometer-zero by means of the control magnet, the main difficulty in the use of the method lies in the fact that at each observation the battery circuit must be kept closed long enough for the galvanometer to come to rest, which in the case of open circuit batteries gives ample time for the errors due to polarisation to appear unless large resistances are inserted in the bridge, thus reducing the sensibility of the method and rendering impossible the use of the convenient slide-wire bridge for such cells. The placing of a condenser in series with the galvanometer as suggested by Prof. Lodge does away with the first and smaller difficulty, but does not help the second. The substitution of a low-resistance telephone in place of the galvanometer very largely obviates both. It possesses the advantages that it responds only to the changes of the current, and is always ready for an observation; hence no delay is necessary after the battery circuit is closed.

To carry out this modified method the slide-wire bridge is connected as in the ordinary Mance's method, the telephone being connected to the ends of the bridge, and an empty wire across from the point between the two resistances to the bridge wire. No sliding contact piece is used, but contact is made by touching the slide-wire with the empty wire with a stroking touch—a fine wire gives the best sound. A key is placed in circuit with the cell, which is closed only at the instant that the connection on the bridge wire is closed. The sharp click of the closing of the key differs so much from the rustling noise of the other contact that there is no trouble in distinguishing the one from the other. The closing of the battery circuit in a series of almost instantaneous contacts gives little chance for polarisation, and the resistances of even the most rapidly polarising cells in common use may be found with a considerable degree of accuracy. For approximate determinations the method is very rapid, the resistance being obtained with an accuracy within a few per cent. almost instantly, and with a little care the determinations can be made practically as exact and satisfactory as with the more complicated Kohlrausch alternating-current method.

INDIAN COAL.†

A noteworthy discovery of coal on the property of the Bengal Coal and Iron Co. was announced lately. Other finds have since been reported from various parts of India, the most important being that referred to at the recent annual meeting of the Nerbudda Coal and Iron Co. It is estimated that this particular deposit contains 10,000,000 tons of good quality fuel—not a prodigious quantity certainly, but still sufficient to represent a respectable accession to the reserves of the company. These discoveries of coal in various districts of India are of interest to the United Kingdom in two or three ways. They must help to solve the whole question of India's ability to cultivate a large iron manufacturing industry. One of the principal deterrents hitherto to any considerable development in this direction has been the lack of suitable coal in quantities large enough to ensure a continuity of supplies. We do not know much that is scientifically definite on the subject of the recent discoveries, and it is quite possible that they may be no better adapted than the bulk of that already produced for the purposes of iron manufacture. On the other hand, finds are so numerous, and are being made in so many widely-scattered districts of the Empire, that there is every likelihood before long of someone unearthing big deposits of good cokeable coal. In the meantime, it is to be noted that the Nerbudda Company expects great profit from its new seam, for it is to be well understood not that fuel of the right sort is not obtained in India, but only that at present there is no great quantity of it available; and the Indian iron industry could not possibly make strides even in the Indian markets if it had a mind to depend upon the United Kingdom for the necessary coal. The increase of production in the dependency is in another way of very direct interest to us at home, for it implies a decrease in the imports of steam coal for railway and factory consumption. Every ton mined is used up, and were double the quantity obtainable there would be little difficulty in disposing of it. For though in steaming qualities Indian coal is poor enough, as compared with that of South Wales, it is possible by the adaptation of furnace bars to use it with good results, and allowing for its initial inferiority, there is a great saving in fuel bills by its employment. The reason for this is quite clear. The chief colliery districts are not very remote from the centres of industrial consumption, especially Calcutta; they are in communication with railways, and what may not be used by the railways is snapped up eagerly by the mills. It is the misfortune of not a few localities where coal occurs in great profusion that they have not yet been brought within the network of railway lines that is gradually spreading over the whole of India. The remedying of this defect is a matter for the future, near in some cases, and rather remote, we are afraid, in some others. But we have much hope that private capital will, on the proper establishment of a gold currency in the country, be induced to supplement the official endeavours. The Government, however, might do something towards aiding the development of the mineral resources, and especially the carboniferous resources of the country.

The present output is in excess of 5,000,000 tons per annum, as compared with 3,537,000 tons in 1895, and less than 2,000,000 tons in 1889. The improvement in the decade is respectable, and would have been greater had the facilities been better. It is only in Bengal that these facilities are at all fair, and this accounts for the fact that that province takes credit at present for about three-fourths of the total for the whole country. Next in importance to it, but a long way behind, comes the Nizam's Territory, which boasts the Singareni Colliery, on the Yellandu field, where coal is estimated to be so plentiful as to be capable of supplying the needs of all the railways of India for the next 100 years. Assam, the Central Provinces, Punjaub, Central India, Burmah, Baluchistan, and other parts contribute to the annual output in fair proportion, and are each and all capable of much better things if only the disabilities were removed and communication given between the mines and the consuming centres. At present, and because the means of communication are imperfect, some districts are dependent almost entirely upon the requirements of the one particular railway which taps them. Thus, the Shahrigh, Khost, Dandot, and Bhaghanwala collieries are worked in connection with the North-Western State Railway. It would be possible, we know, to make too much of the country's future in this matter of coal, especially as the limitations on the basis of discoveries to date are quite clear. But that there is considerable room for the growth of a great home trade will probably be allowed without much dissent.

CORRESPONDENCE.

ELECTRIC POWER SCHEMES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have to thank you for taking up the consideration of the points raised in my letter to the *Glasgow Herald* of August 11th. The question is one of supreme importance to electrical manufacturers in this country, because the financial success or failure of electric transmission schemes very materially affects the prosperity of the industry. My object in opening a discussion on the question is to direct attention as strongly as possible to the importance of the element of increment in value of land to promoters of power transmission schemes. It is exceedingly difficult to distinguish between cause and effect in all such questions, and I do not hope to solve a problem which has baffled the ingenuity of professional political economists.

It is easy, as you say, to too markedly point this moral, but I think you will agree that the success of an electric transmission scheme is likely to be much greater if the promoters of the scheme can reap the fruit of their enterprise in the direction I have mentioned, and also that without the benefit of the return from the land which has improved in value by the transmission scheme, the enterprise has a comparatively small margin of possible profit.

In the present state of the industry it is to be feared that the public are not competent to differentiate between transmission schemes, and it is therefore important that the technical and other press should do it for them.

I am unable to adduce direct proof that the transmission schemes which have been carried out in America and elsewhere depend for their success on the increased capital value of the land, but so far as one can judge from a knowledge of the original capital cost of the land required for the station, the cost of construction and of plant, the annual income earned by these stations leaves an exceedingly small margin for working expenses and profit. Direct information of a qualitative character is easily obtainable and indicates that the most successful schemes have been in the hands of people who have attacked the question from a larger standpoint than

Digitized by Google

simply the sale of electric energy. It may possibly be useful to adduce an example on a small scale.

My company purchased a piece of ground in Glasgow on which an industry now defunct had been carried on. I do not know what is the increment in value of this land due to the establishment of the company's works upon it, but I do know that certain large buildings which it had been found impossible to let, and which were standing empty and inoperative, have been filled with workers by the introduction of electric power supply to tenants at a price of 1d. per unit, which I do not think, on the scale on which it is supplied, would give anything like an adequate return for the capital required for its production. On the other hand, the rents of these premises are such as to afford a very handsome profit to the company on the whole transaction.

This concrete example on a small scale will better illustrate my argument than any amount of abstract reasoning. As an electrical supply the enterprise is hopelessly unprofitable. As a land and property speculation it pays well. That, I believe, is the condition of affairs at Niagara. He would be a bold man who alleged that the supply of electricity from Niagara to Buffalo could be carried out at remunerative prices were it the prime feature of the scheme, and not an incidental means of utilising a large available power at probably a very small profit.—Yours, &c.,

HENRY A. MAYOR.

Glasgow, Aug. 22.

LEGAL INTELLIGENCE.

Electrolytic Plating Apparatus Co. v. Evans & Son.

At the Birmingham Assizes last week the Electrolytic Plating Apparatus Co, of Birmingham and Walsall, sought to restrain defendants, Messrs. Thomas Evans & Son, Walsall, from infringing Letters Patent No. 5,274 of 1896, granted to Messrs. A. S., T. A., R. J., and S. Smith, and T. Deakin, and assigned to plaintiffs. The invention was an improved apparatus for the electro-deposition of metals, and had special application to the electro-plating of small articles. Not only was the deposition of the coating of metal—silver or nickel—obtained, but at the same time the deposition was burnished so that when the articles left the apparatus they were in a finished state. It was explained that each article must be brought into effective contact with the negative pole of the battery. This apparatus dispensed with the necessity of separately connecting or separately wiring each article, which involved a considerable amount of labour, and also simultaneously burnished the articles as they were plated. The plaintiffs alleged that defendants had manufactured and used an apparatus made in accordance with the description in plaintiff's specification. Defendants denied infringement, and pleaded that the patent was invalid.

Mr. COLEFAX, for plaintiffs, said the idea of their invention was old, but the apparatus itself was an absolutely novel invention.

Mr. JAMES SWINBURNE, for plaintiffs, said the only difference between plaintiffs' and defendants' apparatus was that in defendants' machine the tank revolved. That modification—as witness described it—of plaintiffs' apparatus was a disadvantage in his opinion.

Mr. HUGO YOUNG contended, on behalf of defendants, that if plaintiffs' claim were taken in the wide sense it included Zingzam's patent, and made their patent bad. Taken in the narrow sense, giving plaintiffs merely their own modification—the particular mode of contact they had adopted—then defendants had not infringed. Defendants were entitled to their modifications of the original idea, though plaintiffs might have been first to push their goods on the market.

Mr. DUGALD CLARK said plaintiffs' invention contemplated a fixed tank.

Mr. JUSTICE WILLS, in giving judgment, said he had come to the conclusion that judgment must be given for plaintiffs. It appeared to him that the claim was nothing like so wide a one as had been contended by defendants, and that the patentee must be given the benefit as well as be subject to the disadvantage of the common knowledge which existed at the time he gave the specification. To his mind, anybody who had seen the Zingzam patent (which had been cited as an anticipation) would have anything else suggested to him rather than what had been adopted by plaintiff. Therefore he did not think there had been any anticipation. Other inventions of this kind had led to no success, whereas plaintiffs' modification at once gave them success.

Judgment for plaintiffs and an injunction was granted, but, on defendants' application, execution was stayed.

BOOKS RECEIVED.

Copies of any of the undermentioned works can be had from *The Electrician* Office post free, on receipt of published price.)

"An Epitome of the Law and Practice connected with Patents for Inventions," by J. and J. H. Johnson. Third edition. (London: Longmans, Green & Co.) 2s. 6d.

"Electric Generators," by H. F. Parshall and H. M. Hobart. (London: Office of *Engineering*). £1. 11s. 6d.

MUNICIPAL, FOREIGN & GENERAL NOTES.

Aberdeen.—The accounts of the Tramways department for the past year have been issued. The average revenue per car mile of the electric lines was 10·56d. and of the horse lines 11·06d. Over the electric section a greater number of car miles were run than on the horse lines, thus providing greater travelling facilities. The working expenses were 8·31d. for horse traction and only 6·39d. for electric traction, so that the actual profit on the latter is 4·17d., against 2·75d. on the former.

Alfreton.—A curious state of affairs exists here in regard to public lighting. A dispute has arisen between the Council and the local gas company as to the price of gas for street lighting with the result that the town is in darkness at night. A town's meeting has been called by tradesmen to compel the Council to agree to the company's terms, but a resolution endorsing the action of the Council was carried by an overwhelming majority. As electricity works are being erected, it is probable the inconvenience arising from the gas company's action will be soon overcome.

Asylum Lighting.—The Lancashire Asylums Board are to borrow £5,500 to defray the cost of the electric lighing of the new infirmary buildings at Prestwich.

Bath.—Owing to the increased price of coal the charge for electric current for both public and private lighting has been increased a halfpenny per unit, making it 6½d. and 5d. for private lighting and 3½d. for power. Various extensions of the mains were authorised by the Electric Light committee on Wednesday. At the same time the city electrical engineer (Mr. G. F. Metzger) reported that the demand for electric current continued to increase—in fact, the electricity department had never been so busy in making connections.

Beverley (Yorks).—The Council have resolved to obtain electric lighting powers.

Brisbane.—The Council received various offers for the electric lighting concession, some particulars of which were given in our issue of 3rd inst., but after several discussions, it has confessed its inability to decide upon the relative advantages of municipal electricity supply and works owned by a company, and a poll of ratepayers is to be taken to decide this matter.

Bury St. Edmunds.—Electric current was supplied to private consumers for the first time on Tuesday evening last.

Cassier's Magazine.—The September issue includes the following articles: "Electricity in Large Cities," "The World's Coal," and "Gas Engines."

Congo Free State.—The construction of a telegraph line from the West to the East of the Congo State has been decreed. The total length of the line will be 3,750 miles, 775 miles of which is already constructed. The line will ultimately pass through Boma, Leopoldville, Coquilhatville, Stanleyville, Nyangwé, Katambaré and M'Toa.

Consett.—A special meeting of the Council was held last week to consider an application of the Northern Counties Electrical Supply Co. for sanction to a provisional order. Messrs. C. W. Fairweather and J. Pattinson, on behalf of the company, offered to give the Council the right to purchase the undertaking at 10 years at a figure to be determined by the Board of Trade. Electric current would be supplied at 7d. per unit to private consumers, and 4½d. for public lighting, the supply for street lighting to be ready by the season of 1902. After discussion, the Gas committee were instructed to make further inquiries and report.

Crieff.—The proposed application of a company for a provisional order is to be opposed, and the Council will themselves apply for an order.

Darlington.—The town clerk (Mr. H. G. Steavenson) has drawn up a scheme for wiring premises on the hire-purchase system. The wiring is to be carried on under the superintendence of the borough electrical engineer. To cover the cost of superintendence and drawing up a specification a charge of £1 will be made where the cost of wiring (including fittings) does not exceed £10, and for every additional £10, 10s. further will be charged on this account. On completion of the work the consumer will pay to the Corporation 10 per cent. of the total cost of the installation, including the fees referred to. The balance is to be paid in 20 equal quarterly instalments, with interest at 4 per cent. on the amount remaining unpaid, the Corporation making no profit on the work. The approximate cost of an installation of 25 16 c.p. lamps, to be repaid in 20 equal quarterly payments, with interest at 4 per cent. on the balance, has been estimated as follows: Average cost £20, specification £1, deduct 10 per cent. paid on completion of installation, £2. 2s., leaving £18. 8s. due. The first quarterly payment besides the £2. 2s. would be £1. 2s. 8d. At the beginning of the second year it would be £1. 1s. 11d., third year £1. 1s. 2d., fourth £1. 0s. 5d., and fifth 19s. 5d., the last payment being at the end of the fifth year.

Digitized by Google

Devonport.—A lengthy report on public lighting has been prepared by the Lighting sub-committee, in which the Council are recommended to adopt electric lighting for the thoroughfares where electric lighting mains are about to be laid. It is suggested that in seven streets 41 500-c.p. arcs should be erected, to be used till midnight, when 82 16 c.p. incandescents would be substituted. By adopting the scheme the report states that at least 46 of the existing gas lamps would be displaced and the additional annual cost would be £710. 13s., making the total cost of public lighting for the year £3,068. The total illuminating power of the public lamps would be 42,400 c.p., against 13,000 c.p. at present, so that for a further expenditure of about £436 per annum the increased illumination would be over 29,000 candles, or 223 per cent.

Dublin.—At a special meeting of the Corporation on Monday the tenders for the supply of electricity generating plant for the new Pigeon House works (set out in our last issue) were accepted. At the outset communications from the Dublin United Tramways Co. and the Dublin Electric Lighting Syndicate were read. The former company offered to supply electricity in bulk, energy to be delivered to the Corporation mains at the company's Ringsend generating station within the city boundary. If the consumption did not exceed 1,000,000 units per annum the price would be 2¼d. per unit, not exceeding 2,000,000, 2d., and exceeding 2,000,000, 1⅞d. This, it was pointed out, would leave the Corporation complete control over the distribution of electric energy, and that would save them an expenditure on the generating station at the Pigeon House Fort, estimated by Mr. Hammond at £96,000, as well as the cost of mains from the Pigeon House to Ringsend, entailing a charge for interest and sinking fund of some £5,000 a year from the start. Alternatively the company offered to take over the assets, liabilities, and obligations of the Corporation lighting department, including the repayment of the Corporation loan, with interest. The company would then supply current at prices calculated not to exceed in any year an average of 4½d. per unit for the first million units; 4d. for the second million, and 3d. for all in excess, all current for public lighting to be supplied at 2½d. per unit. Should the average prices in any year prove on adjustment to exceed the foregoing rates all surplus receipts would be handed over to the Corporation. Should the average prove to be less than the specified rate, the company would make no claim for the deficiency. This proposal would save all capital outlay by the Corporation (estimated by Mr. Hammond at £254,000 to commence with) and would relieve the Corporation from the repayment of the loan for the existing lighting installation, amounting to over £80,000. The company would provide for taking over the employés on the staff of the Corporation, and, if desired, all street openings could be executed by the Corporation at the expense of the company. The communication of the Dublin Electric Lighting Syndicate stated that they would be prepared in three weeks to submit an offer to the Corporation which would include the following proposals:—The division with the Corporation of all profits after 5 per cent. dividend to the shareholders. The right to the Corporation to appoint two directors on their board. A right to purchase at the end of 20 years. A sliding scale for private lighting based on the average consumption. A right to the Corporation to open the streets at charges to be fixed by the borough engineer. The syndicate would also take over the existing staff and liabilities of the Corporation under their original order.

The Lord Mayor (Sir T. Pile, Bart.), in moving the adoption of the report recommending the acceptance of the tenders, gave a *résumé* of the history of the Dublin electric lighting. He made no apology for having written to these competing companies asking them to make at once whatever specific offer they had to make. What was the position of this question? In 1895 the question of the purchase of the Pigeon House was raised, and one of the strongest arguments in favour of getting it put forward by Mr. Harty, their city engineer, was that it would be a most valuable site for electric generating purposes. That report was unanimously adopted by the Council. On July 9, 1896, the borough engineer pressed on the Electric Lighting committee the urgent necessity there was that provision should be made for the extension of the electric lighting of the city, and on Dec. 2, 1897, the committee adopted, urged, and recommended the proposed erection of the Pigeon House Fort. The Council unanimously adopted the proposal. On Nov. 25, 1897, Prof. A. B. W. Kennedy was appointed their consulting engineer, and on Feb. 18, 1898, he reported that electric lighting from the Pigeon House could be successfully carried out. Sortly after that Prof. Kennedy reluctantly withdrew his connection with Dublin, and Mr. Robert Hammond was appointed in his stead. On Dec. 28, 1899, his scheme in all its details came before them and was adopted. Since that date they had had two of the most exhaustive and searching inquiries by the opponents of this scheme of Mr. Hammond—the Local Government Board inquiry and the Electric Lighting Bill of the Tramway Company promoted in Parliament. In the former case their scheme was declared to be a good one, and in the latter case they succeeded in doing what was practically an unknown thing in getting Parliament to throw out the bill after it had been approved by the Parliamentary Committee to whom its consideration was entrusted and had passed the report stage. Now, as to their proposed scheme. Their proposal was to supply electricity in three mains at 5,000 volts from the Pigeon House to Fleet-street station, and from thence direct to the 19 sub-stations over the city. He emphasised the three mains with three cables, because it had been contended lately, especially by their opponents, that they would be relying on one single main, which, if it gave out, would mean that Dublin would be in darkness. They were going to use two out of the three mains, and the other would be a stand-by; so they might leave out of consideration all likelihood of a breakdown. He would now deal with the offer of the Tramway Company, which was the only tangible offer before them. The committee's report they were now discussing meant the acceptance of tenders for engines, generators, boilers, and fuel economisers at a cost of £46,000, which was £5,000 less than Mr. Hammond's estimate. The practical question at the present point was really whether the Tramway Company were prepared to supply electric current for the lighting of the city at a cheaper rate than the Corporation could manufacture it. The original offer of the company was to supply current at 6d. and 4d. per unit for public and private lighting respectively, reducible at the expiration of two years to 5d. and 3d. That offer was made 18 months ago, and if they had accepted it they would have levied on the citizens a charge of nearly £40,000 a year. A second offer was sprung on the Council just as they were about to apply for a loan to carry out their own work, and now they had sprung a third offer just as they were about to accept tenders. It was not necessary to differentiate between the Tramway Company and the electrical syndicate, because the syndicate was made up by Tramway Company money and directors. They had forced the Council to an expenditure of, roughly, £5,000, and now asked the Council to consider a new offer. By the company's bill, rejected after a struggle by Parliament, and which was the most immoral and audacious proposal ever brought before Parliament, it was sought to fasten on the citizens a lighting charge of 6d. per unit. But the Tramway Company now offered to supply electricity at 2¼d., 2d., and 1⅞d. The Corporation proposal was to supply the consumer for 1½d. To the Tramway Company's charge of 1⅞d., delivered at Ringsend, they had to add 10 per cent. of wastage from Ringsend to Fleet-street, and wages and salaries (put down at £2,700), so that the offer of the Tramway Company would mean a cost of 2½d. per unit to do the same service as the Corporation proposed to do for 1½d. The capital required would be very little reduced by accepting the Tramway Company's offer in bulk. The Tramway Company offered this at low tension at 500 volts at Ringsend. Their proposed system was the high-tension system; but if they put in low-tension mains to carry the electricity delivered at Ringsend it would cost £189,000. Add to that public lighting, £40,000, and meters and house connections, £15,000, and they got a total of £244,500. Now, on the other hand, the Corporation capital expenditure was £103,000 for mains; public lighting, £40,000; generating station, £96,000; and meter and house connections, £15,000; or, in fact, £254,000 of capital, as against the Tramway offer, which would involve a capital cost of £244,000. Adding a provision for interest and sinking fund, electricity delivered by the Tramway Company would cost 4·12d. per unit. If, on the other hand, the Corporation did it they found it would cost 3·37d. The company made an alternative offer; they said if they were given all the electric lighting of the city they would pay the loans due on their stations, take up all responsibility, and supply electricity at 4½d. per unit for the first million, 4d. for the second, and at 3d. for any further supply, and to give public lighting at 2¼d. The average worked out at 3·96d. per unit, while the Corporation scheme worked out at 3·42d. The Corporation would have to pay the Tramway Company £39,133 in perpetuity. All he had to say was, even if their electric lighting did cost more than the Tramway Company's—which he utterly disputed—the difference was this, that at the end of 25 years they would get their property into their own hands, and could reduce the price to consumers to 2d. a unit. There was an idea in the mind of some of the members that their own officials did not quite approve of the Corporation electricity scheme. Mr. Ruddle had some doubt about the scheme, but he said, with Mr. Ruddle's authority, that he was absolutely impressed with the magnificence of the scheme, and believed that it was the best that could be adopted for the city. He (the Lord Mayor) appealed to them to have confidence in themselves, and to believe they were capable of carrying out this great work. They talked of Home Rule, but if they were not capable of carrying out a 2¼d. job like this, they were not capable of governing Ireland.

Mr. Jones seconded the resolution, and said they had only to consider the tenders; that until the division list was issued he would not believe that there were enough men among their 60 members to write themselves down incompetent to carry out this work, which the Local Government Board had given them the money to carry out, and Parliament had given them the right and privilege to carry out.

Mr. Harrington, M.P., said he would not follow the Lord Mayor into the question of the evidence of experts, who were not, after all, independent men. No doubt Prof. Kennedy said the site of the Pigeon House could be worked successfully, but he did not say at what price. What they had to consider was the cheapest and best system, and they were not bound, for any question of sentiment, to expend one penny beyond that. In face of the future expenditure which the city had to face, it seemed to him that the proposal of the Tramway Company was infinitely cheaper than that of their own experts. Why should they ask for tenders for new machinery when not a brick had been laid of the structure in which it was proposed to place it? Unless some better reasons were given why the whole of the tenders were not laid before the Council together he held they should not adopt this report. He was not in favour of giving away the public rights of the city, but if they could get electric light cheaper, without imposing an enormous burden on the rates, he said the practical thing for the Corporation was to get it, and if a profit could be made out of it to endeavour to make it for the benefit of the citizens. He would move as an amendment—"That the consideration of the report of the Electric Lighting committee recommending the acceptance of tenders for machinery, amounting to £46,000 out of an estimated expenditure of £254,000, be postponed until tenders for the building and for the remainder of the machinery, cables, &c., are obtained, so that the amount of tenders for the whole work can be compared with Mr. Hammond's estimate."

Digitized by Google

Mr. TALLON seconded. With regard to Mr. Hammond's figures, they must remember that when on a former occasion an estimate was made from the same source—a comparatively small estimate of £24,000 for a small job—it turned out to be erroneous to the extent of £10,000. When it came to be an estimate running into £254,000 of public money, he felt he must refer to it.

Mr. JONES said the statement was inaccurate. It was a charge against Mr. Hammond which was utterly wrong.

Mr. TALLON (continuing) said he thought they should be afforded time enough to invite and consider tenders from manufacturers in America. He was told that machinery of this kind could be manufactured in America and delivered here better than it could be made in England. There had been such mistakes made in the past that they should be very careful not to go rashly into such large expenditure.

Mr. BRADY said they must remember that they would become immediately responsible for the payment of this large sum of £46,000, the amount of the tenders they were now asked to accept. The loan they were told they had obtained sanction to borrow had been only provisionally granted subject to certain conditions and requirements being carried out by the Council. But those conditions had not been carried out. The plans of the Corporation scheme should be laid on the table. The Local Government Board had not had the terms of the conditional sanction carried out. They were asked to vote for a transaction which was not yet completed—to sanction tenders for machinery without having a place for it.

Mr. H. BROWN said they were told there would be a saving on these tenders of £5,000 on Mr. Hammond's estimate, and perhaps there might be a saving on the other tenders. He was in favour of waiting till the Local Government Board conditions had been fully complied with and the loan had been obtained.

Mr. IRWIN said if they accepted the tenders they would at once incur a liability to Mr. Hammond of £15,000. He asked that the contract should be produced, and having obtained it, read a clause providing that Mr. Hammond should be paid a commission of 5 per cent. on the amount of the contracts as carried out by the contractors. In face of the tremendous difference of opinion that existed in the city amongst experts, he thought it was very desirable and absolutely necessary that all the tenders should be brought before the Council at the same time, so that they might ascertain whether Mr. Hammond's estimate of £96,000 would not run into double that amount, and whether they would be able to produce the light at a profit.

Alderman IRELAND thought the Corporation should enter into a short contract with any company that could supply electricity cheaply, just as they would enter into a contract for coals.

Mr. BEATTIE asked if there was a wastage of 10 per cent. from Ringsend to Dublin, what would the wastage be from the Pigeon House Fort to Dublin? Having regard to the Tramway Company's great plant and convenience to the city, they should be in a position to generate electric current a great deal more cheaply than the Corporation could.

Ald. Sir ROBERT SEXTON said that, while in favour of the Corporation of Dublin having the power to light the city in their own hands, he thought they should endeavour to obtain every possible benefit they could for the ratepayers. He had nothing to do with the Tramway Company, but he thought their proposal should be considered.

The LORD MAYOR, in closing the debate, said their scheme had been approved by the most eminent engineers in England. He went into this scheme originally with a view to force the price of gas down in Dublin. As to the buildings not being ready for the machinery, the first thing was to get the dimensions of the machinery and then to put in the foundations, as it would take longer to complete the boilers and machinery than to build the foundations. Under the arrangement with Clontarf they were bound to supply it with electric current in three or four years. If the tenders now submitted were approved they would have machinery capable of supplying the whole municipal area.

A division was then taken, with the result that 14 voted for the amendment and 38 against, and the Committee's report was then carried by the same number (38 to 14).

Dumfries.—The Council have received several offers for a transfer of their provisional order, but the following terms, offered by one company, seems likely to form the basis of an agreement. All electric current required for public lighting to be supplied to the Council at 7d. per unit for the first hour, and 2d. after, which, for all-night street lighting would work out at 2½d. per unit. The charge to private consumers must not exceed 7d. per unit for the first hour and 4d. after. The Council would also have the option of purchasing the undertaking within twelve months after the expiration of 10 years.

Electric Tramways and Workmen's Tickets.—It is stated that parliamentary agents, who are about to enter upon preliminary work in connection with next year's private bills, have been notified that the revised clause securing better accommodation for workmen, which was inserted in the London United Tramways Bill at the instance of Mr. Lough last session, will be insisted upon in all future measures authorising the construction of tramways. This clause and the old model clause which it is to supersede are—(1) The substitution for the fixed minimum of two workmen's cars morning and evening of the more elastic requirement "a proper and sufficient service"; (2) the alteration of the time limits after which in the morning and before which in the evening workmen's cars will not be required to run from 7 a.m. to 8 a.m. and from 6 p.m. to 5 p.m.; (3) the reduction of the minimum fare from 1d. to ½d.; and (4) the introduction of new provisions compelling the companies to run workmen's cars between noon and 2 p.m. on Saturdays and making the companies liable to a fine of £5 for failure to comply with any order under the section.

Electrical Fire Risk Rules.—We have received from the Royal Insurance Co. a copy of a supplement to the rules for electrical installations issued by this office in which are described special safeguards to be observed with installations of electric light and power plant in factories and works premises, for overhead trolley, telephone and other wires, &c. The supplement is accompanied by a circular in which it is stated that "it does not appear to be sufficiently known to electrical engineers and to the users of electrical power installations that, in certain special risks, motors and other appurtenances must conform to the installation regulations of the associated fire offices in order to be allowed without an extra charge. It is important (continues the circular) to note that the only type of motor or dynamo which is allowed free when not situated in an engine room or in its own separate compartment is the fully enclosed type. A mere box turned over the motor is not accepted as a compartment, which must be of such size that a man can enter it to attend to the machine."

Fatal Accident.—At an inquest opened at Liverpool last week into the death of a labourer named M'Gurn, 22, employed by the Liverpool Corporation Tramways, it appeared that during the thunderstorm of Aug. 3 deceased was changing horses in Robson-street, when an electric trolley wire fell on his head. He was severely injured, and died the same night in Stanley Hospital. It was not known whether the wire was blown down, or had fallen through some defect of construction. The inquest was adjourned to 23rd inst. It was stated that that was the first accident of the kind that had occurred since the inauguration of electric traction, and the coroner thought that fact was sufficient to show that reasonable care had been exercised in connection with the construction and fitting up of the overhead equipment. A verdict of accidental death was returned, no blame attaching to anyone.

Gloucester.—The electricity undertaking is making excellent progress, and considerable extensions of the street arc lighting system are contemplated.

Goole.—"In order to keep out companies," the District Council will apply for electric lighting powers.

Haiti.—The Haitian Government announce that they are about to introduce electric lighting into the capital (Port au Prince). This Government have also decided to cancel all existing concessions for lighting cities of the State, paying the holders for their plant and other expenditure, in order that the lighting may be under Government control.

Halifax.—Three new electric tramway lines were officially inspected by the Board of Trade electrical inspector, Mr. A. P. Trotter, on Wednesday. About 15 miles of electric tramway owned by the Corporation are now open for traffic. The Booth Town route to Queensbury, and the continuation of the Cote Hill branch to Hebden Bridge will be the next tramways to be constructed.

Hanley.—On Tuesday tenders were accepted for the supply of additional plant for the electricity works, and it was decided to apply for sanction to borrow £7,000 to cover cost. The chairman (Ald. Hammersley) pointed out that from January to July the electricity department had generated 473,000 units of current, and had sold 311,000 units only. They were exceedingly anxious to find out where the leakage could be. With regard to domestic lighting, it was found that the consumption in many cases had been so small that the meters would not register the current, and that they hoped also to remedy shortly.

Hastings.—An inquiry was held here on Friday into the application of the Council to borrow £3,650 for electric lighting extensions. Technical particulars were supplied by the borough electrical engineer, Mr. Leonard Andrews. There was no opposition.

Hull.—A special meeting of the Parliamentary committee of the Hull and District Chamber of Trades was held last week to discuss the action of the electricity department of the Corporation in placing fuse-boxes in front of business premises. Messrs. Craft & Son complained that a fuse-box had been erected in front of their premises at the corner of Beverley and Fountain-roads at a distance of 5ft. 6in. from one of their principal windows. It had proved and was proving a great inconvenience to their trade. The attention of the Electric Light committee had been drawn to the matter, and the town clerk had informed them that they were prepared to remove the box to another site on condition that the cost of removing it (£10) was paid by the firm complaining. The meeting unanimously resolved that the erection of fuse-boxes in front of tradesmen's premises was a serious inconvenience, and a deputation was appointed to wait upon the committee in regard to the matter.

Ilford.—The foundation stone of the new electricity station building was laid by the chairman of the Council (Councillor H. Weeden, J.P.) on Saturday. Current is to be supplied for lighting and tramways. Councillor Weeden said the main thoroughfares were to be lighted electrically, and the Council were constructing an extensive system of electric tramways, which would, he said, be the

Digitized by Google

most modern in existence. The lines would connect all the districts of the parish, and would provide ready and cheap means of transit. The Council were prepared to supply current at the lowest possible price, so that it should be to the interest of every householder to have the electric light in his house. Councillor Bailey afterwards laid the foundation stone of the chimney shaft. The consulting engineer of the scheme is Mr. W. C. C. Hawtayne.

Jungfrau Railway.—The *Schweizer Handels Zeitung* states that since last winter the Jungfrau Railway works have not advanced, have, in fact, been entirely suspended for the last few months. The published traffic returns are said to be inaccurate. The project (the cost of which is heavier than set out in the estimates) is in danger of being abandoned.

Leeds.—The Briggate, Hunslet and Thwaite Gate electric tramway route was opened for traffic on Friday last.

Light Railways.—The Board of Trade have confirmed the Gateshead and District Light Railway Order.

A comprehensive scheme for the construction of light (electric) railways in Surrey is being formulated, which includes a line from Chobham to Woking, Send, Ripley and West Horsley, and one from Walton-on-Thames to Weybridge and Addlestone.

Liverpool.—The wholesale fish market is now lighted by 20 arc lamps, current being supplied by the Corporation electricity department for the first time on Wednesday.

Llandudno.—The condenser at the electricity works is to be extended at an estimated cost of £1,500.

Manchester.—The negotiations for the purchase of the National Telephone Co.'s business in Manchester having fallen through, the special Telephone committee have entered into negotiations with the Mutual Telephone Co., who offer to provide, under certain conditions as to compulsory sale to the Corporation, a telephone service for £5 a year to shareholders and £6. 10s. a year to non-shareholders. The chairman of the company (Mr. W. Thompson) waited on the committee on Wednesday and gave an explanation of an agreement entered into by the Mutual Company with Salford Corporation, It is stated that the committee will next consult the Salford Corporation, and it is thought possible that eventually arrangements will be made which will enable the Mutual Company to obtain a licence to start a competitive system in the city. In the event of the failure of the negotiations the committee will consider the question of the establishment of a municipal service.

Newark.—The Council are considering the question of carrying out the terms of their provisional order, and the consulting engineer (Mr. C. S. Vesey-Brown) has been instructed to report on the cost, &c., of an electric lighting scheme.

Newcastle-on-Tyne.—The General Purposes sub-committee of the Council have already purchased 100 cars for the electric tramways and have decided to purchase 35 more, which will provide 20 spare cars for special occasions. The time-service of these cars has just been revised over all the principal routes, and the number of cars considerably increased.

Nottingham.—The Corporation have decided to light the electric tramway routes by arc lamps, and Mr. W. J. Furse has secured the contract. Arc lights are to be attached to every alternate tramway pole.

Nuneaton.—The Council have considered and approved the report of their consulting engineer (Mr. W. C. C. Hawtayne) on the present condition of the electricisy works and on the advisability of making extensions to the plant and mains. The report stated that the site of the station is good, being close to the business portion of the town, and feeders could be run economically to the outlying portion of the district. Mr. Hawtayne pronounces against the proposal to change the site of the works, and considers that the best course to be followed would be to erect entirely new buildings and to place new machinery in these buildings when completed. Of the present plant the steam dynamos are pronounced serviceable, but Mr. Hawtayne recommends that new boilers be substituted for the old ones, and that the storage batteries and such switchboard arrangements as cannot again be made use of should be scrapped. A new battery of accumulators will be required when the new works come into operation. The re-arrangement of the mains by the resident engineer (Mr. W. J. Proctor), the change over from overhead to underground cables, and the change in the system of distribution from two to three-wire, are favourably commented upon in the report. Mr. Hawtayne recommends the Council to erect 16 arc lamps for the eleetric lighting of the market place, the displacement of about 27 of the existing posts, and the provision of two incandescent lamps of, say, 32 c.p. each, to be switched on at midnight when the arcs are extinguished. Mr. Hawtayne's report has been accepted by the Council, and the amount for which borrowing powers are to be sought has been increased from £8,000 to £10,000.

Paraguay.—A company entitled the Paraguay Development Co. was recently formed in Philadelphia (U.S.A.) to exploit and develop "the natural resources of South American countries, and especially of the Republic of Paraguay," including the erection of electricity and other lighting plants, the construction of electric tramways, &c. It is stated that an American capitalist will shortly go to Paraguay to arrange for lighting Asuncion, the capital, and for building a trolley tramway line.

Party Line Telephones.—The following letter from A. R. Bennett, general manager of the Glasgow Municipal Telephone department, appeared in the *Glasgow Herald* of 23rd inst. :—

Referring to the description of the Party Line telephone apparatus which is proposed to be introduced in Glasgow by the National Telephone Co., which appeared in your issue of Aug. 21, I think it desirable in the public interest to point out that there is really nothing new about the system. The Party Call System is as old almost as telephones themselves, having been introduced under the name of the Individual Call System well back in the eighties. Under that name the National Telephone Co. themselves gave it an extensive trial, with results that did not justify its continuance. Making a call by lifting off the telephone was practised in London in 1880, and has always been a distinguishing feature of the Post Office telephones, which, nevertheless, have never enjoyed much public favour. Making signals by incandescent lamps is not a novelty, and possesses no practical advantage over a signal made by moving a disc or shutter. That it looks pretty may be admitted. Why the Individual Call System, or, to give it its new-fangled name, the Party Line System, was not a success, and never can be a success, is due to the fact that no two of the parties joined on the same line can use it at the same time. If A and B are on the same line, B cannot call the exchange if A is using it; and if any other subscriber calls for A while B is using the line, A loses his connection, which may mean much to him. When the complication is increased by the presence on the line of C, D, E, F, G, and H (I see that it is proposed to put as many as eight persons on one line), the confusion which results may be imagined. It must be borne in mind that telephone subscribers have a tendency to use their telephones at the same hours every day, the hours which correspond to the deliveries of letters and the closing of mails, so that attempts to use the line simultaneously are apt to be the rule rather than the exception. The National Telephone Co. state in their public advertisements that persons who take advantage of the Party Line rates must not join an opposition exchange; consequently those who sign such an agreement will be precluded, for one or two years at least, from taking advantage of the £5. 5s. telephone service offered by the Corporation, and at the same time may find that the disadvantages indicated above are very far from being imaginary.

Personal.—Mr. Andrew S. Dunn, who has been superintendent of telegraphs to the Caledonian Railway Co. for the past 33 years, has intimated his intention of retiring in October. Mr. Dunn is one of the oldest telegraph officers in the United Kingdom, and an original member of the Society of Telegraph Engineers. He was also president of the conference of railway telegraph superintendents and engineers in 1889. Mr. Dunn joined the Electric and International Telegraph Co. in 1853, and, after some time became assistant to the superintendent for Scotland in Edinburgh. In 1867 he was appointed superintendent of the northern section of the Caledonian Railway telegraph system at Aberdeen, and in 1869, on the State acquiring the telegraphs, was appointed to Glasgow as superintendent over the entire Caledonian Railway system. During his association with the Caledonian Company the telegraph department has expanded enormously, and from small beginnings in 1867, when the number of electrical instruments used in railway working were counted by hundreds, they are now counted by thousands. Electric lighting has also been introduced in the principal stations and hotels of the company. For 33 years Mr. Dunn has regularly accompanied the royal train conveying the Queen to and from her Balmoral residence.

Picketing.—In the Vacation Court, London, yesterday, Mr. Justice Farwell held a special sitting to hear an application on behalf of the Taff Vale Railway Co., to put a stop to the picketing prevailing on the Great Western railway at Cardiff, and after hearing the evidence produced his lordship granted an injunction against Mr. Richard Bell, general secretary of the Amalgamated Society of Railway Servants, and against Mr. James Holmes, organising secretary of the society for the West of England. The application for an injunction against the Amalgamated Society of Railway Servants was ordered to stand over for his lordship's reserved judgment on Wednesday next.

Preston.—The Council are recommended by the Streets and Buildings committee to introduce electric traction on the local tramways, the present lease of which expires in 1902. The Council obtained electric traction powers in their 1900 act.

Provisional Order Revocation.—The Board of Trade have revoked the Newbury Electric Lighting Order, 1892.

Rhyl.—The Council are anxious to raise a loan of £40,000 for electric lighting and other works, and a deputation has been sent to London to negotiate.

Rome.—The Anglo-Roman Gas Co., a British venture of old standing, owns the concession for lighting Rome and district by both gas and electricity. The amount of electric current supplied by the company for lighting during 1899 was 17,854,017 hectowatts, against 15,412,139 in 1898. The tramway company in Rome took from the

Digitized by Google

Anglo-Roman Co. 24,174,933 hectowatts of current in 1899, compared with 11,263,309 in 1898. This large increase was due to the new lines opened during the year. The demand for current for lighting and traction necessitated a considerable extension of the works and plant at Tivoli, and an issue of 4½ per cent. debentures to the amount of £200,000 was authorised during the year, and a portion of the bonds issued.

Rothwell.—All applications by companies for a provisional order are to be opposed, and the Council will itself apply for electric lighting powers.

St. George's (London).—A special meeting of the Vestry was held on Friday to consider a proposal to rescind resolutions passed in favour of the electric lighting of the streets and authorising the Electric Lighting committee to enter into a contract with the Westminster Electric Supply Corporation. Mr. Burch, who moved the original resolution, now moved its rescission. The motion was seconded by Mr. P. T. Saunders, who thought the parish was sufficiently and adequately lighted, and he considered they had, so far as gas lighting was concerned, a perfect parish. He regarded the electric lighting scheme as a monstrous and mischievous one, and a wilful and scandalous waste of public money. After a discussion the rescinding resolution was adopted by 21 votes to 3, but a squabble appears to have occurred after this voting, and a further division resulted in 23 voting for the rescission and 13 against, and as a two-thirds majority is required to rescind a resolution of the Vestry the motion fell through. A resolution that the committee should submit a report to the Vestry before entering into an agreement with the Westminster Co. was subsequently carried.

St. John's (Newfoundland).—Electric tramways are now running through all the principal thoroughfares of this city, the length of line at present constructed being over 7 miles, and considerable extensions are already being considered. Power for these electric lines, as well as for lighting St. John's, is generated 9 miles from the city, the generating plant being of 1,600 H.P. capacity, with flume capacity for an additional plant of equal size. Westinghouse power-house equipment has been installed.

St. Michael's (Azores).—The advent of the submarine cable has undoubtedly called attention to the island of St. Michael's as a health resort, and the possibilities of the place as a competitor with Madeira are considerable. Only capital is required to develop Fournass, Sept Citades and other favoured spots on the island, and it is reported that the first step towards popularising St. Michael's will be the construction of an electric railway. Already it is announced that English capital is backing private enterprise in the building and maintenance of a line to run from Ponta Delgada, to be commenced at once and to be completed within four years. The introduction of an electric line would undoubtedly lead to the establishment of hotels, and, if only the pest of voracious flies in some districts can be combated, there is an excellent outlook for St. Michaels, where an extremely pleasant holiday can be spent. Fournass possesses many attractive features, amongst which may be reckoned some well-equipped iron and sulphur baths which at present are free.

Samara (Russia).—Electricity supply works have been started in this town.. The plant has been supplied by the Siemens and Halske Aktien Gesellschaft of St. Petersburg.

Sheffield.—The Electric Light committee have resolved to send a small deputation to Paris to collect information as to the progress made in electric lighting and traction plant as exemplified by the machinery on view at the Exhibition. The deputation will visit other cities on the Continent where electricity works have been established. The committee propose to erect a new power station in Sheffied, and information is being sought for the guidance of the Council.

Soothill Nether (Yorks.).—Owing to the increase in the price of gas the District Council are making enquiries into the cost of electric lighting.

Sunderland.—Since the recent opening of the electric tramways attempts have been made to wreck the cars. On two occasions iron slabs 1in. thick have, it is stated, been laid across the lines after dusk, but on each occasion the driver has detected the obstruction in time. The latest device has been to insert steel punchings within the groove of the rails. A reward of £20 has been offered by the Corporation, but notwithstanding constant vigilance so far no trace of the culprit has been discovered.

Tariff Changes.—The Russian Empire Customs tariff has been extended to the region of the Amur both at the ports at the mouth of that river and to the south of it, and also on the land frontier. Among the articles to be imported free of duty are dynamo electrical machinery, driving bands, &c.

Torquay.—An inquiry was held here last week into the application of the Council to borrow £15,000 for electric lighting extensions. The town clerk (Mr. F. S. Hex) explained that the Council's electricity undertaking had developed so rapidly that the additions to the plant made in 1899 were insufficient to meet the demand for current. At the end of March, 1898, there were 55 consumers, but on March 31 last the number was 221. The total equivalent number of 8 c.p. lamps connected in March, 1898, was 5,688, of which 3,310 were private lamps, and in March last there were 10,070 lamps. Several applications in hand could not be dealt with. The total revenue for the first year was £2,837, last year it was £3,699. There was a gross profit of £1,057 the first year, and of £1,256 the second year, but after allowing for interest and sinking fund (£1,188) there was a deficit of £138 on the first year, and a profit of £67 on the second. Technical details were given by the borough electrical engineer, Mr. P. Storey. There was no opposition.

Water Power Utilisation in Spain.—Electric traction is to be adopted on the Bilbao-Durange-Arratia Railway, the contract for the conversion having been secured by the French Thomson-Houston Co. The water power of the Falls of Maguras and Garay are to be utilised in the generation of electrical energy.

Workhouse Lighting.—The plans and specifications prepared by Mr. G. R. Peers for the electric lighting of the Christchurch workhouse and cottage homes have been approved by the Buildings committee of the guardians.

Wrexham.—The Council have fixed the charge for electric current at 6d. per unit for lighting and 3d. for power.

Yeadon.—A canvass of ratepayers on the electric lighting question has been made. Of 890 circulars distributed 510 were returned, 337 in blank. Of the remaining 173, 98 were in favour of electric lighting and 75 against. At a meeting of the Council on Friday the chairman proposed that the provisional order be transferred to a syndicate, but only the mover and seconder voted for it. There were also two against, and the chairman declined to give a casting vote. The Yeadon order was obtained in 1894, and some time ago the Board of Trade decided to defer the question of its revocation until the end of October.

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers, or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London:—

"The Electrician" Reading Case.—To hold four numbers of the journal. Strongly bound, 1s. net; post free, 1s. 4d.

"Localisation of Faults in Electric Light Mains."—By F. C. Raphael. Price 5s., post free. The book deals with the important subject of localising faults in electric light and power cables; and the various methods of insulation testing are here collected and discussed.

"Wireless Telegraphy: Signalling across Space without Wires by Electric Waves." A Review of the Work of Hertz and his Successors.—By Dr. O. J. Lodge, with a large number of illustrations, bringing this latest application of electrical science quite up to date. New and Enlarged Edition, 5s. nett. *Now ready.*

"The Centenary of the Electric Current, 1799-1899."—By Dr. J. A. Fleming. Price, paper covers, 1s. net, post free 1s. 3d.; strong cloth, s. 6d., post free.

"Motive Power and Gearing for Electrical Machinery."—By E. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free. In this comprehensive work an account is given of the scientific principles and modern practice in the use of engines for dynamo driving, not only for isolated power plants, but also for public electric lighting and power stations. The various forms of gearing in the power station and for electric motors are also dealt with; and the book contains, in addition, numerous tables giving exact data of the equipment and working of electric power stations.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. *New and Cheaper Edition*, 6s., post free.

"The Students' Guide to Submarine Cable Testing."—A new edition of this book, by Messrs. H. K. C. Fisher and J. C. H. Darby, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated.

"Electro-Chemistry."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"The Incandescent Lamp and its Manufacture."—By Gilbert S. Ram. Price 7s. 6d., post free. The principles underlying the manufacture of the incandescent lamp are carefully and fully dealt with in this volume.

"The Manufacture of Carbons for all Electrical Purposes."—by Francis Jehl. 10s. 6d., post free. This is a practical handbook, giving a complete description of the art of making carbons for electric lighting, electrodes, &c., with particulars of the various gas generators and furnaces used in carbonising. The work also contains particulars of the cost, &c. of erecting and working carbon works, and plans of a model factory.

"Magnetic Induction in Iron and other Metals."—By Prof. J. A. Ewing. Price 10s. 6d. net. *New Edition (Third) now ready.*

IN THE PRESS.

"The Electric Arc."—By Mrs. Ayrton.

"Secondary Batteries, their Design and Manufacture."—By E. J Wade.

"Primary Batteries: Their Construction and Use."—By W. R. Cooper.

"Practical Telephony."—By Dane Sinclair and F. C Raphael.

"'The Electrician' Wireman's Pocket-book."—Edited by F. C. Raphael. *Nearly ready.*

Digitized by Google

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office no later than first post Thursday morning. New Catalogues, Price Lists and similar matter should be sent early in the week.]

TENDERS INVITED.

Whitby District Council invite tenders for the supply and erection of electricity generating plant, some particulars of which are set out in an advertisement. Specification may be obtained at the offices of the consulting engineers (Messrs. Preece and Cardew), 13, Queen Anne's-gate, Westminster. Tenders, addressed to the clerk (Mr. Wm. Seaton Gray), Council offices, Whitby, must be in before noon of Sept. 3.

The Vestry of St. John, *Hampstead* (London) invite tenders for the supply and erection of (1) eight dry-back marine boilers, (2) steam and water pipes, feed pumps, &c., (3) feed-water heater, or (4) feed-water detartariser, (5) fuel economiser, (6) cast-iron water tank, and (7) two blow-off tanks. Conditions and specifications may be obtained at the offices of the vestry clerk (Mr. Arthur P. Johnson), Vestry Hall, Hampstead, N.W., to whom tenders must be delivered by 4 p.m. of Sept. 27. An advertisement contains further particulars.

Oldham Electric Light committee invite tenders for the supply and erection of dry-back marine boilers, with mountings, gangways, feed and drain pipes, &c., complete, and also for mechanical stokers with shaftingand gearing for driving; or water-tube boilers as an alternative to the dry-back marine boilers, including mountings, &c. Further particulars are given in an advertisement, and copies of specifications may be obtained from Mr. A. Andrew, Gas and Water offices, Oldham. Specification and drawings can also be seen at, but not obtained from, the offices of the consulting engineer (Dr. Alex. B. W. Kennedy), 17, Victoria-street, Westminster, S.W., and tenders must be sent to the superintendent (Mr. A. Andrew) on or before Sept. 11.

London County Council invite tenders for the supply of mains required in connection with the scheme for the electric lighting of the Victoria Embankment and Westminster Bridge. Further particulars are given in an advertisement, and specifications, &c., may be obtained at the engineer's department, County Hall, Spring Gardens, S.W. Tenders must be addressed to the clerk (Mr. C. J. Stewart) before noon of Sept. 24.

London County Council Asylums committee invite tenders for boilers, engines, dynamos, &c., at Horton Estate, Epsom, Surrey. Tenders to committee, 6, Waterloo-place, S.W., by 10 a m. of Sept. 22.

Dundalk District Council invite offers for the transfer of their provisional electric lighting order. Some particulars are set out in an advertisement, and any further information can be obtained at the office of the borough surveyor. Tenders to the town clerk (Mr. Mathew Comerford), Town Hall, Dundalk, before 1 p.m. Sept. 18.

Mexborough District Council invite tenders for electricity generating plant, particulars of which are set out in an advertisement. Copies of the specification, &c., can be obtained from the electrical engineer to the Council (Mr. H. Waring), 18, Berkeley-road, Crouch End, London, N., and tenders must be delivered to the clerk (Mr. J. W. Hattersley), Mexborough, before Sept. 15.

Glasgow Corporation invite tenders for the supply and fitting-up of the power station piping required at Pinkston. An advertisement contains further particulars, and specifications, &c., can be obtained from the general manager (Mr. John Young), 88, Renfield-street. Tenders to the town clerk (Sir J. D. Marwick), City Chambers, Glasgow, by 5 p.m. Sept. 28.

Salford Corporatfon invite tenders for twelve months' supply of high and low-tension single and concentric cables, house fuse boxes, meters and meter boards. Particulars may be obtained from the borough electrical engineer (pro tem.), Mr. F. A. Wilkinson, Walness-road, and tenders must be delivered to the town clerk (Mr. L. C. Evans), Town Hall, Salford, before Sept. 10. See advertisement.

Walthamstow District Council invite tenders for the supply and erection of electric lighting plant and apparatus, including gas plant, gas engines, dynamos, switchboard, boosters, balancer and measuring instruments. Specifications may be obtained from the consulting engineer (Mr. James Enright), 47, Victoria-street, London, S.W., after Sept. 4. Further particulars are given in an advertisement, and tenders must be delivered to the town clerk (Mr. E. J. Gowen), Town Hall, Walthamstow, by 5 p.m., Sept. 25.

Sunderland Corporation invite tenders for triple expansion high-speed direct-current steam dynamos, Lancashire boilers, and feed pumps. Specifications may be obtained from the borough electrical engineer (Mr. J. F. C. Snell), Dunning-street, Sunderland, and tenders (addressed to the chairman of the Electric Lighting committee) must be sent to the town clerk (Mr. Francis M. Bowey) by noon of Sept. 21. An advertisement gives further particulars.

Dublin Electric Lighting committee invite tenders for the supply and laying of electricity supply mains and accessories. Specification may be inspected at the office of the city engineer (Mr. Spencer Harty), City Hall, Dublin, and may be seen at and obtained from the offices of the consulting engineer (Mr. Robert Hammond), 64, Victoria-street, London, S.W., after Sept. 3. Further particulars are given in an advertisement, and tenders, addressed to the town clerk (Mr. Henry Campbell), City Hall, Dublin, must be in by 4 p.m. of Oct. 4.

Tenders are invited for the electric lighting of the new drill hall, *Portsmouth*. Specifications can be seen on the works, and other information obtained from the architect, 148, High-street, Portsmouth, and tenders must be sent to the Col.-Commandant (A. R. Holbrook), Drill Hall, Alfred-road, Portsmouth, by 5 p.m. Sept. 10.

Hackney (London) Electric Lighting committee invite tenders for condensing plant, cooling apparatus, pipework and valves, feed pumps, switchboard and boosters, arc lamps, meters, travelling crane, and workshop equipment. Tenders to vestry clerk by 4 p.m., Sept. 12.

Hammersmith (London) Vestry require tenders for the supply, delivery and erection of two single-phase alternate-current motors, coupled to two centrifugal pumps, with accessories. Tenders to clerk before 5 p.m., Sept. 12.

The managers of the *Poplar* and *Stepney* Sick Asylum District invite tenders for sundry work in connection with a telephonic installation at their sick asylum. Tender to clerk, Bromley, Middlesex, by 5 p.m., Sept. 17.

Hull Electric Lighting committee invite tenders for steam and water pipes, feed-pumps, water-softener, &c., for their Sculcoates-lane generating station. Tenders (addressed chairman of committee) to town clerk's office by noon, Sept. 27.

Aberdeen Electric Lighting committee invite tenders for two 200kw. direct-coupled continuous-current generators and one 120kw. balancing set; also for one 420kw. direct-coupled continuous generator. Willans engines are specified in both cases. Tenders to city electrical engineer by Sept 29.

Tunbridge Wells Corporation invite tenders for high and low-tension cables. Tenders to town clerk by Sept. 29.

Greenock Police Board invite tenders for water-tube boilers, two steam dynamos, boosters, switchboard, steam and exhaust pipes, &c. Tenders to town clerk (Mr. C. MacCulloch) by Sept. 10.

Nelson Corporation invite tenders for a 200kw. steam dynamo. Tenders to town clerk by Sept. 8.

Southampton Guardians invite tenders for electrical plant and an electric lighting installation for the new workhouse infirmary at Shirley Warren. Tenders to clerk St. Mary-street, Southampton, by Sept. 11.

Southampton Harbour Board invite tenders for a 30-cwt. portable electric wharf crane. Tenders by Sept 17.

Luton Town Council require tenders for watt and demand meters. Tenders to town clerk by Sept. 14.

Salford Cleansing committee invite tenders for a two or three cell and also a six cell refuse destructor. Tenders to town clerk by Oct. 2.

Tenders are invited for the electric lighting of the *Fife and Kinross* District Lunatic Asylum. Tenders to clerk, Cupar-Fife, by Sept. 3.

Tenders are invited until Nov. 4 by the municipal authorities of *Philippopolis* (Bulgaria) for the concession for electric lighting.

Up to Nov. 2 the Civic Administration of *Piatra Neamtz* (Roumania) is open to receive tenders for a concession for the lighting of the town by electricity for 30 years. The local administration will supply further particulars.

The "Madrid Gazette" of 20th inst. contains a notice calling for tenders for the electric lighting of Vélez Blanco up to March 1, 1920, on the basis of 110 incandescents (30 16 c.p., 60 10 c.p., and 20 5 c.p.). The upset payment to the Municipality is to be 3,000 pesetas (£92) per annum.

TENDERS RECEIVED AND ACCEPTED.

Barnes District Council received the following tenders for the supply of condensing plant, &c., and an overhead travelling crane, for their electricity works:—

Section E.—*Condensing plant, pumps, oil filters and separators, feed, steam, and exhaust pipes, &c.*

Babcock & Wilcox (*accepted*)	£2,239	Aiton & Co.	£2,596
Cole, Marchent and Morley..	2,860	Alley and MacLellan	2,480
Jas. Simpson & Co.	2,800		

Section F.—*Overhead travelling crane.*

Chatteris Engineering Works Co. (*accepted*)	£264	John Whitley & Co.	£400
		Jas. Carrick & Son	265

The tenders so marked have been accepted on the recommendation of the consulting engineer (Mr. Wm. Fairley).

Dudley Town Council have accepted the tender of the Worthington Pumping Engine Co. for the supply and erection of condensers, pumps, cooling tower, &c., for their electricity works.

The tender of Messrs. Crowther & Co. has been accepted by the Grimsby Corporation for wiring the electricity works.

Digitized by Google

APPOINTMENTS VACANT AND FILLED.

Partick Commissioners require a resident engineer to take charge, under the superintendence of their consulting engineers (Messrs. Kincaid, Waller and Manville), of the erection of electric lighting plant and the laying of mains. An advertisement contains further particulars, and applications must be lodged with the town clerk (Mr. James Donaldson), Burgh-chambers, Partick, by Sept. 24.

A superintendent of mains is required by the Salford Electricity Department. Applications to be addressed to the borough electrical engineer (pro tem), Mr. F. A. Wilkinson, Electricity Works, Walness-road, Salford, by Sept. 5. See advertisement.

The Gas and Electric Committee of Belfast Corporation require an assistant electrical engineer to take charge of the meter, motor and testing department. Salary £120 per annum. Applications to the city electrical engineer (Mr. Victor A. H. M'Cowen) by noon of Monday, Sept. 10. See advertisement.

The Jandus Electric Co. (Ltd.), Hartham Works, Hartham-road, London, N., have a vacancy for an assistant electrician. See advertisement.

Sheffield Corporation require a meter superintendent, cable jointers, and an engine driver for their electricity department. Applications to the chief engineer and manager (Mr. S. E. Fedden) by Sept. 6. See advertisement.

Two shift engineers are required for the South Shields Corporation electricity works. Applications to borough electrical engineer (Mr. Jos. A. Jeckell) before Sept. 5. See advertisement.

Four telegraph linesmen are required for the Natal Government Railways. An advertisement contains further particulars, and applications should be addressed to the Agent-General for Natal, 26, Victoria-street, London, S.W.

A demonstrator and assistant lecturer in physics is required for the University College of South Wales and Monmouthshire, Cardiff. Applications to secretary by Sept. 9.

Mr. A. A. Day, chief assistant engineer of the Manchester Corporation electricity department, has been appointed borough electrical engineer of Bolton in succession to Mr. Arthur Ellis, who was recently appointed electric tramway engineer at Cardiff. The commencing salary is £500, advancing by yearly increments of £50 until the maximum of £750 is reached. There were 44 applications for the appointment, and these were first reduced to 12, and then to four, namely, Mr. A. A. Day; Mr. J. A. Jeckell, borough electrical engineer of South Shields; Mr. H. F. Street, borough electrical engineer of Halifax; and Mr. W. R. Wright, borough electrical engineer of Bootle. These appeared before the joint Tramways and Electricity committee on 17th inst., when Mr. Street was conditionally appointed. In this connection it is interesting to note that a special meeting of the Halifax Town Council in committee was held on Thursday last to consider a recommendation from the Gas Committee to increase the salary of Mr. H. F. Street from £400 to £500 per annum. This recommendation was due to the fact that Mr. Street had been offered the latter sum as a commencing salary by the Bolton Corporation. The Halifax Council, after a protracted discussion, however, declined by 18 votes to 17 to sanction the advance.

Bristol Electrical committee have appointed Mr. K. O. Hale clerk of works for the construction of the foundations of the new electricity station buildings at Avonbank.

BUSINESS NOTICES.

Messrs. T. Harrison and M. Brown (trading as Harrison and Brown), electrical engineers, &c., 79, High-bridge, Newcastle-on-Tyne, have dissolved partnership. Debts by Mr. Brown.

Messrs. H. Ambler and P. E. Caswell, electrical accessory factors, trading as Ambler and Caswell, 8 and 9, Lincoln's Inn, Birmingham, have dissolved partnership. Debts by Messrs. Abbott, Deeley, Hill & Co., Bennett's-hill, Birmingham.

Messrs. Holme, Ringer & Co., Chemulpo, Corea, are open to receive catalogues (preferably in duplicate) of electrical and telephonic machinery, overhead and underground telegraph and telephone wires, and general telegraphic, telephonic, and other electrical apparatus.

BANKRUPTCIES, LIQUIDATIONS, &c.

In the bankruptcy of Wm. Dalzell (trading as Wm. Dalzell & Co.), electrical engineer, Newcastle-on-Tyne, the trustee (Mr. J. G. Gibson) has been released.

A receiving order has been made against F. L. L. Lindsay, electrical and mechanical engineer, Gorphwysfa, Llandegfan, Anglesey, and 216, High-street, Bangor.

In the Court of Session, Edinburgh, last week, a petition for a supervision order in connection with the liquidation of P. C. Middleton & Co. (Ltd.) was heard by Lord Low. The company was incorporated in December, 1898, with a capital of £50,000, in 14,000 ordinary and 36,000 5 per cent. preference shares of £1 each, and 6,153 preference shares and 10,381 ordinary shares were fully paid. The company was formed to carry on the business of electrical engineers, &c., but owing to the whole of its authorised capital not being subscribed, it did not possess sufficient ready money to enable it to carry on its business and to meet its present liabilities. Accordingly the company went into voluntary liquidation, and a liquidator was appointed by the shareholders. In terms of an arrangement, his lordship appointed Mr. R. Reid, advocate, 46A, Union-street, Aberdeen, and Mr. S. Easton Simmers, C.A., 58, Bath-street, Glasgow, joint liquidators, to whom claims against the company are to be sent within 14 days.

Meetings of the shareholders and creditors of the Gutta Percha Corporation (Ltd.) were held in London on Friday last. The chairman (Mr. Winearls, assistant receiver) stated that the company, which was to trade in and manufacture gutta-percha, was promoted by the Omnium Syndicate and the Globe Venture Syndicate. The purchase consideration was £150,000—£120,000 for patent rights, and £30,000 for the stock of gutta-percha leaves and other things sold to the company. The sale was conditional upon the company's proceeding to allotment before Oct. 14, 1897, on a subscription of £30,000, but only £25,280 was subscribed. In spite of favourable reports in the prospectus the company did not appear to have been able to manufacture gutta-percha of marketable value, and its total sales of stock amounted to £14. The action of the directors in proceeding to allotment upon insufficient subscription, contrary to the provisions of the purchase agreement, required further investigation. The statement of affairs disclosed total liabilities £20,303, of which £15,110 were stated to be unsecured, and no available assets, the whole of the amount (£5,195) being covered by debenture bonds. The total deficiencies as regarded creditors and shareholders was returned at £177,067. The official receiver continues to act as liquidator.

Creditors of Easton, Anderson and Goolden (Ltd.), in liquidation (which liquidation has, like many others in the electrical and engineering industries, dawdled on till creditors have become hopeless of any satisfactory outcome), have received a circular, dated Aug. 28, from Mr. W. B. Peat, the liquidator, notifying that the Court has sanctioned a contract for the sale of the business to a new company, to be called Easton & Co. (Ltd.), subject to the calling of meetings of the debenture stockholders and shareholders, and to a reservation as to certain cash assets available for distribution as a first dividend to creditors. A meeting of creditors is called for Wednesday, Sept. 12, at 12:30 p.m., at the Guildhall Tavern, Gresham-street, London, E.C., to consider the conditional agreement sanctioned by the Court. Under this agreement the new company pays interest to the debenture stockholders from July 1 last, and issues to them debenture stock of the new company, which pays as purchase consideration to the old company £252,000—£27,000 in cash, £150,000 in first mortgage debenture stock, £30,000 in preference shares, and £45,000 in ordinary shares. The cash portion of this purchase-money goes to liquidate the arrears of interest on debentures to June 30, 1900, advances made by the receiver, and other expenses. The ordinary shares (£45,000) will be held by the liquidator on account of creditors.

A creditor of the Fowler-Waring Cables Co. (in voluntary liquidation) desires to know the present position of this winding-up and whether the liquidators, who have had this matter in hand so long, will vouchsafe some public statement as to the progress made in the transfer of the business to the Western Electric Co. We ourselves think it due to creditors and others that some such public statement should be made. In the meantime we can only refer our correspondent to the liquidator, Mr. J. A. Blackwood.

While on the subject of these liquidations it would be interesting to have particulars of the final stage of the winding-up of Woodhouse and Rawson (Ltd.). What has become of Mr. Leslie!

Plant for Sale.—Messrs. Fuller, Horsey, Sons and Cassell will sell by auction at the Old Mill Works, Cowley Mill House, near West Drayton, Middlesex, on Thursday, Sept. 20, at 12 noon precisely, a quantity of engineering and electrical plant and machinery, some particulars of which are set out in an advertisement. Catalogues can be had of Messrs. Pond & Sons, 6, Butter Market, Ipswich, and of the auctioneers, 11, Billiter-street, London, E.C.

Water Power for Disposal.—Mr. Frederick Warman, surveyor, 66, Chancery-lane, W.C., is offering water power at Wandsworth, London, S.W. See advertisement.

"Simplex" Conduit.—The Simplex Steel Conduit Co. have issued a new supplementary list to their main catalogue in handy form, and amongst the latest improvements in this type of conduit we illustrate in Fig. 1 a "Simplex" split pendant box with internal dimensions of 2⅛in. by 1¼in. by 1in. This box is provided with bridge terminals and a connection box for connecting by branch circuits from a pair of bars fitted on to porcelain in the box. Fig. 2 shows a set of removable porcelain interiors and connection bars for use in "Simplex" standard junction boxes. This arrangement

Digitized by Google

consists of a porcelain cradle which just fits inside the junction box and supports the two brass connecting bars, the latter being made in two parts. The bars are drilled between the supports along their length and terminal screws are fitted to clamp the branch circuit

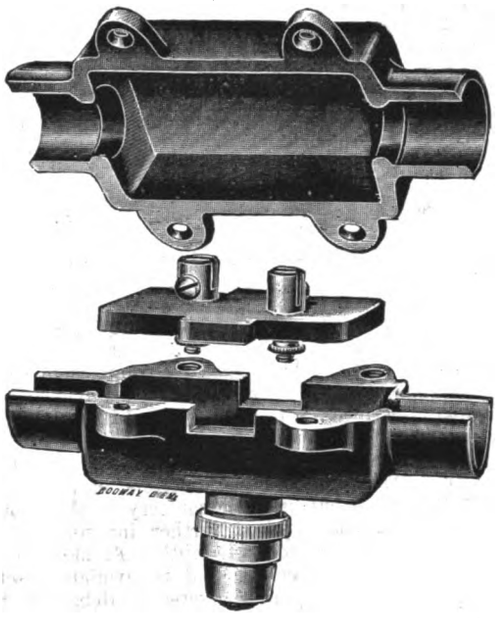

FIG. 1.

wires, a half-lap joint in the middle allowing the two ends to be easily sweated on to the main lead into the thimble-bored ends, which are provided to receive the cable. Amongst other improve-

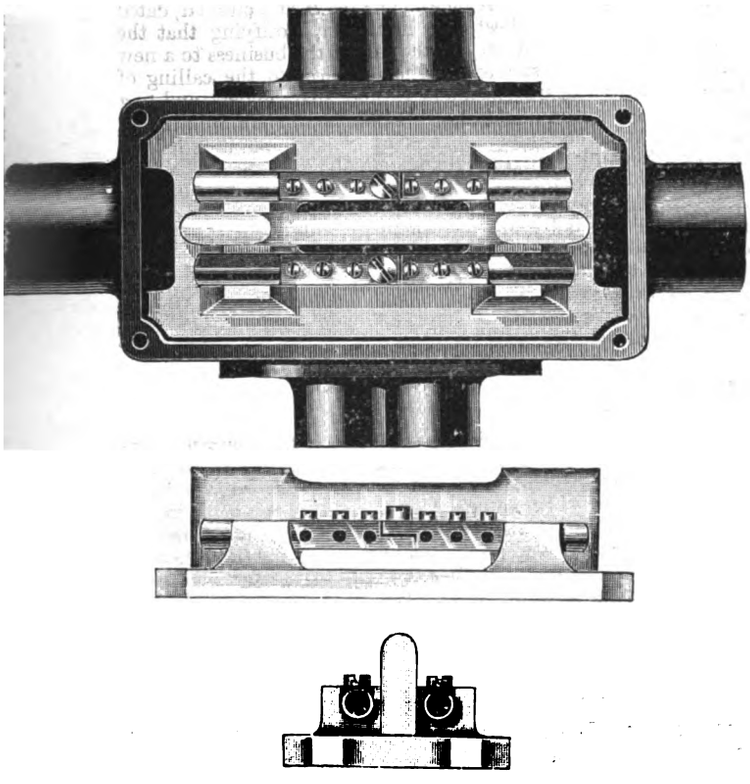

FIG. 2.

ments may be mentioned a screwed brazed conduit of heavy gauge and screwed fittings, for use where a water-tight system is imperative. The list also illustrates a new type of box enamelled iron-cased switch and fuse distributing board fitted with a deep cast-iron glass-fronted cover, which allows the box to be easily wired and the fuses to be readily replaced. Some very cheap "Simplex" brackets are also shown with terminal or through boxes having nipples to suit ⅜in. conduit.

Paris Exhibition Awards.—In extension of the list of awards which appeared on p. 679 of our last issue, we may mention that in Class 15 (scientific instruments) Mr. Mark Barr was awarded a gold medal for a three-dimensional engraving system, the most essential mechanism of which was a microphonic micrometer measuring a length of 4·5in. 10 times in succession within the $\frac{1}{50000}$ part of an inch. Mr. Barr thus secured one of the only four gold medals awarded to English exhibitors of mathematical and scientific instruments.

In connection with the award of a gold medal to the Electrical Power Storage Co., Mr. H. W. Butler, chief engineer to the company, was awarded a silver medal in recognition of the excellence of the manufactures of this exhibit.

In connection with the exhibit of the Simplex Steel Conduit Co., for which a gold medal was awarded, Messrs. L. H. Lander and L. M. Waterhouse were granted a silver medal as "collaborators."

Messrs. A. C. Wells & Co.'s awards included a silver medal for the "Wells' light," a silver medal for their "Lightning" painting machine, and a "mention honourable" for waste oil filters, "Unbreakable" lamps and oil feeders, and "Industrial" lamps.

Messrs. Salviati, Jesurum & Co. (Ltd.), of 14, St. Paul's Churchyard, London, E.C., were awarded a gold medal for electrical chandeliers and other fittings.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Aug. 22 to Aug. 28, with the ports of destination :—

Aden—£40 (telegraph apparatus). *Africa*—Alexandria, £83; Beira, £104 (including £44 telegraph material); Durban, £1,353; East London, £78; Port Elizabeth, £148. *Argentina*—Buenos Ayres, £1,112 (including £133 telegraph material). *Australasia*—Adelaide, £1,218 (including £700 telegraph wire); Fremantle, £60; Hobart, £53; Launceston, £214; Lyttleton, £697; Melbourne, £228; Sydney, £948; Wellington, £884 (including £387 telegraph cable). *Brazil*—Bahia, £32; Rio Janeiro, £188,592 (telegraph cable and material). *Ceylon*—Colombo, £81. *China*—Shanghai, £35. *Colombia*—Santos, £17. *Germany*—Hamburg, £1,050 (telegraph material). *Holland*—Amsterdam, £144; Flushing £16. *Hong Kong*—£320. *India*—Bombay, £407; Calcutta, £60; Karachi, £123. *Japan*—Kobe, £33; Nagasaki, £142. *Malta*—£29. *Mauritius*—£74. *Russia*—Libau, £330; St. Petersburg, £175. *Siam*—Bangkok, £110. *Straits Settlements*—Singapore, £166. Total £199,150, against £9,940 in the corresponding week last year (Aug. 23 to Aug. 29).

PATENT RECORD.

The following list of Applications for Patents and Specifications published has been compiled for this journal by MESSRS. J. C. CHAPMAN and Co., *Chartered Patent Agents, of 70, Chancery-lane, W.C., from whom any available information in connection with Patents, Designs, and Trade Marks may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned Applications are not open to public inspection until after the acceptance of the complete Specification. The names within parentheses are those of communicators of inventions. When complete specification accompanies application, an asterisk is affixed.*

June 21, 1900.

11,243. THE BRITISH ELECTRIC WORKS CO. (LTD.) and B. BRANDER. Birmingham. Improvements in polarised electric bells for alternating current.

11,255. A. W. B. PEARSON. London. A new or improved composition used for making electrical insulators and other articles.

11,260. A. TRIBELHORN. London. Improvements in electric accumulators and in electrodes therefor.

11,263. H. HIRST. London. Improvements in or relating to electric lamps and fittings therefor.

11,264. H. HIRST. London. Improvements in or relating to switchboards for electric distribution.

11,272. J. HOFBAUER. London. Improved means of and apparatus for preventing the premature starting of dynamos or the like used in connection with electric lifts.*

11,287. F. JONES. Liverpool. Improvements in or relating to conduits for electric conductors.

June 22, 1900.

11,340. M. FISCHER. Germany. Improvements in and connected with electric clock work.

11,344. W. L. VOELKER. London. Improvements in the manufacture of filaments for incandescing electric lamps.

11,358. H. N. WOLLASTON and J. V. SHERRIN. London. Improvements in or connected with secondary batteries.

11,361. J. G. S. LEE. London. Improvements in ceiling roses or attachments for pendant electric lamps.

June 23, 1900.

11,406. A. ZEHDEN. London. Improvements in the electrical equipment of railway vehicles for the purposes of lighting, skating, and ventilation.*

11,429. M. VOGELSANG and F. LINDENSTRUTH. Liverpool. An improved electromaguet of high attractive force.*

Digitized by Google

11,437. E. Risler. London. Improvements in electric insulators.
11,438. Siemens Bros. & Co. (Ltd.), W. Dieselhorst and F. J. Budd. London. Improvements in casings for the jointings of underground electric cables.*

June 25, 1900.

11,471. H. E. Walter. London. Improvements in electro-magnetic brakes.
11,486. J. V. Sherrin. London. Improvements in means for preventing sparking in electric switches, commutators, current conductor contacts, contact breakers, and other electric devices.
11,500. P. H. F. Spies. London. Improvements in arc lamps.
11,519. H. G. Nicholson. London. Improvements in frogs to be used in connection with overhead conductors of electrical tramways and railways.

June 26, 1900.

11,547. G. Hill. Manchester. Improvements in fittings for overhead trolley systems of electric tramways.
11,555. W. L. Wise. London. Improvements in apparatus for driving phonograph cylinders. (The Germania Phonographen Compagnie (Ltd.), Germany.)
11,555. M. W. Hanks. London. Improvements in terminals and supports for Nernst lamp glowers.*
11,557. H. N. Potter. London. Improvements in ballast resistances and cutouts for Nernst lamps.*
11,558. A. J. Wurts. London. Improvements in systems for lighting by Nernst lamps.*
11,559. A. J. Wurts, H. N. Potter, and M. W. Hanks. London. Improvements in starting apparatus and cutouts for Nernst lamps.*
11,560. A. J. Wurts and M. W. Hanks. London. Improvements in terminal connections and supports for Nernst lamps.*
11,561. A. J. Wurts, H. N. Potter, E. Bennett, and M. C. Beebe. London. Improvements in Nernst lamps and heaters therefor.*
11,562. P. C. Hewitt. London. Improvements in electric lighting.*

SPECIFICATIONS PUBLISHED.

Note.—All Specifications can now be obtained at the uniform price of 8d. each.

1899.

13,996. Veritys Limited and Ridings. Electric arc lamps.
14,224. Alcock. Apparatus for electrically transmitting orders, signals, or indications from one place to another.
14,467. Pease and Burdon. Electric traction with overhead conductors.
14,568. Eggerding. Electrical alarm apparatus.
14,668. Farrell. Moveable electric lights.
14,906. Davis. Fuse blocks for electric circuits. (Date applied for under International Convention, Jan. 30, 1899.)
14,907. Davis and Wright. Electric circuit breakers. (Date applied for under International Convention, Mar. 23, 1899).
14,908. Mershon. Method of and apparatus for indicating potential in systems of electrical distribution. (Date applied for under International Convention, Feb. 1, 1899.)
14,909. Lamme. Dynamo-electric machines. (Date applied for under International Convention, April 14, 1899.)
15,128. Lucas. Plug contacts or contact plugs for electric circuits.
15,138. Lamme and Mallet. Electric generators and motors. (Date applied for under International Convention, Feb. 6, 1899.)
15,139. Wright and Aalborg. Automatic electric circuit breakers. (Date applied for under International Convention, March 23, 1899.)

1900.

7,567. Brown. Electric bonds for electrically connecting the meeting ends of two contiguous electric conductors.
7,594. Thompson (Hogan). Graphophones or phonographs.
7,606. Lindstrom, Hewitt and Hewitt. Electrical controlling switches.
7,695. Galsworthy. Wall plugs for electric lighting and heating.
7,851. Riebensahm. Electric incandescent lamps.
8,152. Wise (Actien-Gesellschaft Elektricitätswerke vorm. O. L. Kummer & Co.). Electric transformers.
8,160. Ely. Electric switches.
8,239. Siemens Bros. & Co. (Ltd.) (Siemens and Halske Aktien-Gesellschaft). Electricity meters constructed on the Ferraris principle.
8,299. Johnson (Dercum). Two-liquid primary batteries and regenerating the same.
8,300. Johnson (Dercum). Two-liquid primary batteries and regenerating same.
8,433. Dannert. Process for the production of electrically conductive illuminating bodies.
8,476. British Thomson-Houston Co. (Ltd.) and Hobart. Induction electric motors.
8,584. Tosi, De Felice and Parboni. System of electric traction by surface contact.
8,586. A. C. Martin. Galvanic battery.
8,682. Conant. Apparatus for measuring electrical resistances and chiefly intended for testing the electrical resistance of rail joints in the tracks of electric railways. (Date applied for under International Convention, Nov. 13, 1899.)
8,894. Koller. Electric smelting furnaces.
9,331. Haas. Electrolysing apparatus.
9,398. Doersch. Electric shampooing apparatus.
9,464. Husselman. Manufacture of filaments for incandescent electric lights.
9,503. Bergmann. Electric igniters for explosion engines.

NEW COMPANIES, STATUTORY RETURNS, &c.

ABERDARE ELECTRIC LIGHT CO. (LTD.)—This company was registered on Aug. 23, with a capital of £2,000 in £1 shares, to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity for light, heat, motive power or other purposes.

FINCHLEY ELECTRIC LIGHT CO. (LTD.)—This company was registered on Aug. 22, with a capital of £3,000 in £1 shares, to acquire from Mr. M. W. Woods the concession for supplying electric light and power on the Finchley Manor estate, and to carry on the business of an electricity supply company in all its branches. The subscribers are C. H. Cribb, consulting chemist, L. Bradley, electrical engineer, M. W. Woods, electrical engineer, A. W. Marshall, electrical engineer, A. W. Sclater, electrical engineer, W. A. Hogarth, and W. R. Estall. Mr. M. W. Woods is a permanent director.

HUMPAGE, JACQUES AND PEDERSEN (LTD.)—This company was registered on Aug. 24, with a capital of £10,000 in £1 shares (3,500 preference), to carry on the business of electrical, mechanical, and general engineers, tool makers, &c. The first directors are M. Pedersen, J. Harrop, and T. Humpage.

UNION CABLE CO. (LTD.)—This company was registered on Aug. 24, with a capital of £25,000 in £1 shares, to manufacture and deal in submarine and other cables, telegraphs, telephones, and electrical appliances and apparatus, and to carry on the business of cable and rope manufacturers, mechanical and electrical engineers, &c. The subscribers (with one share each) are E. E. O Pelland (electrical engineer), A. J. Wilson, F. H. Miller, E. A. Rehder, J. V. Varela, G. Runge, and R. W. Cawse.

BRITISH THOMSON-HOUSTON CO. (LTD.)—According to the annual return to Aug. 6 the capital is £400,000, in £10 shares, all of which have been taken up. £10 has been called up on each of 16,531 and £3 10s. on each of 16,000 shares, and £221,310 has been received. 7,469 shares are considered as fully paid.

CALCUTTA TRAMWAYS CO. (LTD.)—In the annual return to July 31 the capital is given as £350,000, in 35,000 shares of £10 each, 34,440 of which have been taken up. £10 has been called up or credited as paid on each share, and £159,300 has been received. £185,100 is considered as paid on 29,090 shares.

CHADBURN'S (SHIP) TELEGRAPH CO. (LTD.)—The annual return to June 22 gives the capital as £120,000, in 60,000 ordinary and 60,000 preference shares of £1 each, all of which have been taken up.

EDISON AND SWAN UNITED ELECTRIC LIGHT CO. (LTD.)—The annual return to Aug. 14 has been filed. The capital is £1,000,000, in 150,000 "A" and 50,000 "B" shares of £5 each, of which 116,400 "A" and 23,564 "B" shares have been taken up. 10s. has been called up on each of 89,261 "A" and £44,630. 10s. has been received. £456,667. 10s. is considered as paid on 10,000 "A" (£3 credited), 89,261 "A" (£2 10s. credited), and 17,139 "A" and 23,564 "B" (credited as fully paid).

ELECTRIC CONSTRUCTION CO. (LTD.)—The annual return to July 26 gives the capital as £400,000, in 150,000 ordinary and 50,000 preference shares of £2 each, of which 112,100 ordinary and 25,000 preference have been taken up. £2 per share has been called up and paid on 2,100 ordinary and 11,855 preference shares. £246,290 is considered as paid on 110,000 ordinary and 13,145 preference shares.

GLOBE TELEGRAPH AND TRUST CO. (LTD.)—According to the annual return, to Aug. 10, the capital is £5,000,000, in 250,000 preference and 250,000 ordinary shares of £10 each, of which 180,042 preference and 180,227 ordinary shares have been taken up and paid for in full.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since July 19, 1900). Price of silver 28⅜d. per oz. (Aug. 30). Consols (2¾ per cent.) 98¼—98⅜ for money, 98¼—99⅜ for account; 2½ per cent. 97½—97⅝ (Aug. 30). Stocks and Shares Continuation Day, Sep. 12; Ticket Day, Sep. 13; Pay Day, Sep. 14; Mining Share Carry-over Day, Sep. 11.

ALUMINIUM AND CASTNER-KELLNER ALKALI AMALGAMATION.—The necessary resolutions for the amalgamation of the Aluminium and the Castner-Kellner Alkali Companies have been passed at meetings of members of both companies.

BLACKPOOL AND FLEETWOOD TRAMROADS CO.—The half-yearly meeting was held on August 23. The chairman (Mr. G. Richardson) regretted the decrease in the receipts over the corresponding period last year. The weather had affected their tramway in a manner greater than most tramways, because they had more holiday and fine weather traffic than any other tramway in the kingdom. They had carried 660,006 passengers during the half-year, the gross receipts being £10,125. 17s. 2d. The cost of maintenance was £363. 19s. 1d., against £466. 17s. for the June half-year 1899. Generation expenses, in consequence of the price of coal, had shown an increased expenditure of about £200. The traffic expenses were £2,249. 19s. 3d., a slight increase; and the general expenses showed a decrease of about £20. The expense per mile was 7¾d., against 8¼d. for the corresponding half-year of 1899. In the December half of 1899 the expense per mile was only 7¼d. The receipts per mile were 11½d.

Digitized by Google

MARCONI'S WIRELESS TELEGRAPH CO. (LTD.)—A meeting is to be held on the 5th prox. to consider and confirm a proposal to issue £25,000 additional capital in this company at £3 per share. The shares will be offered in the first place to shareholders.

W. T. HENLEY'S TELEGRAPH WORKS CO. (LTD.)—At an extraordinary meeting on Friday last, presided over by Mr. S. Gedge, M.P., the resolutions passed on 8th inst., increasing the ordinary capital from £150,000 to £200,000 (by the creation of 10,000 additional £5 ordinary shares), and the preference capital by the creation of 10,000 additional £5 preference shares were confirmed. The chairman announced that it had been decided to offer the new ordinary shares at £10 each, and shareholders would receive an allotment of one-sixth of their present holding.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee has appointed Sept. 13 a special settling day in £125,000 4½ per cent. debenture stock of the *Potteries Electric Traction Co. (Ltd.)*, and has ordered the stock, as well as the further issue of 9,400 ordinary £5 fully-paid shares (Nos. 17,401 to 17,407 and 26,108 to 35,000) of *Edmundson's Electricity Corporation (Ltd.)*, to be quoted in the Official List.

WINDERMERE AND DISTRICT ELECTRIC SUPPLY CO. (LTD.)—The annual meeting was held on Monday. The chairman (Mr. W. Long) stated that the trading profit for the year was £1,112, and after payment of interest, &c., there was a balance of £970, and of this £949 had been applied to payment of dividend on the preference shares and the remainder carried forward. The company had acquired the undertaking of the Keswick Electric Lighting Co., and had come to an arrangement with the Ambleside Council to take over their provisional order on favourable terms. Mr. J. S. Raworth regretted the non-payment of a dividend on the ordinary shares. The directors had come to the conclusion to raise the price of current for lighting from 6d. to 7½d. per unit. In reply to a question, the managing director (Mr. F. Fowkes) said the company had no connection with the British Electric Traction Co. further than having entered into a contract to supply that company with electrical energy as soon as the Lake District tramway of that company was constructed.

WIRRAL RAILWAY CO.—At the half-yearly meeting the chairman (Mr. T. A. Jackson) stated that, having obtained powers to work the line by electricity, the change would be proceeded with when a favourable opportunity presented itself. The directors anticipated good results from the change in motive power.

NOTES.

THE annual meeting of the British Association for the Advancement of Science was inaugurated at Bradford on Wednesday. The public proceedings commenced with the presidential address of Sir WILLIAM TURNER, the eminent Professor of Anatomy at Edinburgh University. The PRESIDENT took for his subject the cell theory of life, and sketched in an interesting and instructive manner the progress of knowledge of living tissue. The subject has just this much in common with electrical science, and indeed with all scientific inquiry, that it admirably illustrates how advance has always been made by the unfolding or evolution of previous discoveries. Thus, from a knowledge of the essential relation of tissue to life, biologists passed to the establishment of the essentially cellular nature of all tissue, and at the present stage the internal structure of the cell itself is being gradually unfolded. Prior to the inaugural address, at a meeting of the General Committee, the question was raised as to the admission of women as members of the General and Sectional Committees. A motion, advocating their admission, was brought forward by Prof. HARTOG and seconded by Prof. SILVANUS P. THOMPSON, and after some debate was carried by a substantial majority. Before, however, this proposal can be practically adopted, it must go before the Committee of Recommendations, and be subsequently reported by this committee to another meeting of the General Committee. It is to be hoped this routine can be gone through before the Bradford meeting is concluded. The meetings of the various sections began yesterday with the delivery of the presidential addresses. We commence this week a full report of Dr. LARMOR's address to Section A, the subject of which will be found of extreme interest to students of the dynamics of the ether in relation to electrical and magnetic phenomena.

THE inquiry of the Board of Trade Commissioners on the boiler explosion which took place on July 25 last at the Crystal Palace District Electric Supply Co's. works at Sydenham practically attributes the disaster to a boiler badly made in the first instance, and badly looked after during its use. Although constructed only nine years ago, and apparently built for a working pressure of 140lbs.—at about which pressure it has been in actual use—the boiler-makers had employed cast-iron, in place of a more reliable metal, for such important details as some of the stays supporting the crown of the firebox. Messrs. HORNSBY & SONS freely admitted at the inquiry that the boiler was defective, but pleaded that at the time the boiler was made they had in their employ an engineer who subsequently had been dismissed for passing bad work! The Engine, Boiler and Employers' Liability Insurance Co.'s inspector appears also to have been at fault, the Commissioners stating that he had not, in their opinion, made adequate examination of the boiler. Moreover, the Commissioners appear to have thought that, besides his electrical and other qualifications, the resident chief engineer and manager, Mr. A. L. PHILLIPS, ought to be a boiler expert. The Crystal Palace District Supply Co. were ordered to pay £150 towards the costs of the inquiry, and the above-named insurance company £50; but the boiler makers were let off because the boiler was made so long ago! Surely this last was a curious reading of the Statute of Limitations, when it is remembered that the makers admit having built the boiler with inherently defective parts, the failure of which was the immediate cause of the explosion. If, as we understand, Messrs. HORNSBY are cautioning users of this type of boiler against their continued use, and undertake to overhaul these boilers free of charge, some good may come from the inquiry, which does not seem to have altogether placed the burden of guilt, if we may so term it, upon the right shoulders. A feature of the case was a singularly inconsequent report upon the boiler by another insurance office expert.

THE correspondence columns of *The Times* recently have given expression to a not altogether unnatural anxiety on the part of the general public to know what may be expected to happen when a train of the Central London Railway type of underground railway is brought to a standstill midway between two stations through temporary stoppage of electric power. Suffocation in Egyptian darkness seems to be the fate most feared. We hasten to say that no fate is more improbable. The deserved popularity of the "Twopenny Tube" need suffer no detraction on account of such fears, which are utterly baseless. Even the discomfort of being plunged into darkness need not occur, for lights other than the electric lamps are provided on every train. As to suffocation, the numerous shafts at the stations along the line, to say nothing of trains moving in other parts of the tunnels, must maintain a continual circulation of fresh air. On this subject Sir BENJAMIN BAKER has sent an authoritative —if in some parts gruesome—letter to *The Times*, which we reprint below :—

In reply to the inquiry of "A. F. B.," as to what would happen in the event of a train filled with passengers being stopped for half-an-hour in the middle of a tunnel on the Central London Railway or other of similar construction, will you permit me to say that the purity of the air breathed by the passengers would be practically unaffected, but that the temperature might appear somewhat high in contrast to the cold tunnel unless the end doors and side ventilators were all kept open? Numerous experiments on a scientific basis have proved that the oppressive condition of air sometimes complained of in railway carriages above or below ground is related to the temperature and not to the purity of the air; so that, whilst in summer people may complain of being suffocated though all the carriage windows are open, in winter they feel no such oppression though they remain all night in a well-filled carriage with every window and ventilator studiously closed. It has been practically demonstrated by physiological and chemical experiments that a live man might be sealed up in a lead coffin for half-an-hour without any resultant feeling of oppression—I say nothing of depression—provided he were treated as frozen mutton in a cold store, so that the air he breathed, though astoundingly foul from repeated breathing, might still remain cold. The worst that could happen from a stoppage of many hours in a small tunnel would be that some of the passengers might get as warm as if they were in the cheap seats of a theatre, assuming they remained in the carriages, which is not at all likely, as convenient gangways are provided along which passengers could walk to the nearest station, and supplementary lights are available in the event of a breakdown of the ordinary system.

AN important change in the system of electric supply at Sheffield has been proposed by the City electrical engineer, Mr. S. E. FEDDEN, in a report dated 24th August, reprinted on another page. From the outset Sheffield has been under the disadvantage of having a high-frequency alternate-current system of supply. This, combined with various troubles from time to time in the working of the plant, has tended to hinder the natural growth of the load. It will readily be seen that as regards motor load this high frequency is practically fatal. It is not at Sheffield only that supply station engineers have had to grapple with this same difficulty. In some places it has been solved by conversion from the alternating to the continuous-current system, in others by the introduction of supplementary continuous-current plant for a separate motor load, and in still other places polyphase machinery has been introduced. There have been alternate-current systems, however, which, owing to being planned at the start to work on a low frequency, have been able to develop a considerable motor load: the municipal station at Derby is a notable instance. The problem presented to Mr. FEDDEN, therefore, has been to select the best of several practicable solutions; and he has recommended his Electric Light Committee to adopt that one which certainly would involve the least possible change in the existing works, viz., to adhere to the single-phase alternate system, but to reduce the frequency from 100 ∿ to 50 ∿. Evidently Mr. FEDDEN has become a disciple of Mr. FERRANTI, who, on several occasions recently, has preached the efficacy of the low-frequency single-phase current for general supply to lamps and motors. Mr. FEDDEN's report has been referred to Mr. R. HAMMOND, and we understand that Mr. HAMMOND's report on it is about to be forwarded to the Committee. Meanwhile, Mr. FEDDEN is accompanying a deputation, consisting of the Chairman and Vice-Chairman of the Committee, to the Paris Exhibition, where the latest electrical machinery is to be inspected, and from thence to Frankfort, where there is a magnificent object lesson in single-phase electrical distribution for lighting and power.

ON February 11, 1898, we announced than an ingenious telegraphic instrument, invented by Messrs. CREHORE and SQUIER, and called by them a synchronograph, had been tested on the British Post Office land lines, the longest loop tried being 1,097 miles in length—viz., from London to Glasgow and back by different routes. Considerable development in this instrument, we believe, has taken place since that date, and at the International Electrical Congress at Paris, in the Telegraphy and Telephony Section, on the 23rd ult., a Paper was communicated by the joint inventors, giving a description of their latest practice with this instrument. An abstract of the Paper appears in our issue this week. In the discussion which followed the reading of the Paper, Mr. GAVEY, of the General Post Office, commented on the claims made by the authors as to the relative increase in transmitting speed, and described some of the experience on British lines. He stated that as they could always get full speed out of the ordinary Wheatstone system anywhere within the limits of the British Isles, by the use of repeating instruments, the Crehore and Squier system of sinusoidal transmission had not been adopted. He further considered that the results obtained by the inventors compared none too favourably with the British Wheatstone practice, because it was necessary for the inventors to experiment with their system at night or at other times when the neighbouring wires were quiet, and he believed that in the busy hours with other land lines at work, the inductive disturbances would greatly reduce the apparent advantage. We hope at an early date to give some further particulars of the sinusoidal system of operating the Wheatstone receiver.

Cable Interruptions :—	Date of Interruption.
Latakia—Cyprus	June 21, 1899
Cayenne—Pinhieros	Oct. 11, 1899
Tangier—Tarifa	Jan. 3, 1900
Ceara—Maranham	Feb. 20, 1900
Pará—Maranham	Mar. 2, 1900
Môle-St. Nicolas—Cap Haitien	Mar. 7, 1900

University College, Nottingham.—The next session commences on Oct. 8th, and courses of instruction in mechanical, electrical and civil engineering extending over two and three years are given at this college. Prospectuses can be obtained from the secretary.

A False Alarm.—The rumour having been circulated that the fire in the subway at Charing Cross *originated* with the telephone wires, we may assure our readers that such was not the case. Telephone wires, our non-electrical readers may care to know, are not a source of fire risk.

Northampton Institute (Clerkenwell, London).—In addition to the engineering day courses at this Institute, evening technical courses have been added in all branches of electrical and mechanical engineering. These classes will commence on Monday, Sept. 24. Particulars can be obtained at the Institute or of the principal, Dr. R. Mullineux Walmsley.

Iron and Steel Institute.—Arrangements have been made for holding a meeting of the above Institute in Paris from Sept. 17 to Sept. 20. On the 18th inst. the President will deliver an address in the Hall of the Société d' Encouragement, and a number of Papers will be read and discussed, while on the following day the remainder of the Papers will be disposed of. The rest of the visit will be occupied in paying visits, attending receptions, &c. A detailed programme may be obtained of the secretary, at 28, Victoria-street, S.W.

Paris Exhibition Literature.—The second part of "L'Electricité à l'Exposition, de 1900," which is being edited by MM. Hospitalier and Montpellier and published by Vve. Charles Dunod (Paris) has just appeared. It is from the pen of M. Montpellier himself, and deals with the continuous-current dynamos generating current for the light and power supply of the exhibition. The machines are taken *seriatim* and a condensed description of each is given, the two German continuous-current machines being omitted however. There appears to be no attempt at literary style, the particulars of the machinery being simply written down in short sentences, most of which commence with "le," "la," or "les." Some good drawings illustrate the text, however, but the photographic views of the various units are for the most part badly executed. The volume should be useful as a record, and we look forward to reading the next number, already due, on the alternating-current sets.

The German-American Cable.—A Reuter's telegram, dated the 31st ult., announces that Herr von Podbielski, the German Secretary of State, has received the following telegram from the German Emperor:—

I am much pleased at the successful completion of the laying of the cable between Emden and New York. I give you my best thanks for the intelligence, and congratulate you on the speedy execution of this work, which is of such importance for our Fatherland, and which, as I confidently expect, will contribute to strengthen and increase the relations between two friendly peoples. As an expression of my satisfaction with your successful efforts, I appoint you *à la suite* of the Third Regiment of Ziethen Hussars. WILHELM, I.R.

His Majesty also sent the following telegram to President McKinley:—

On the opening day of the new cable, which brings Germany into the closest telegraphic communication with the United States, it gives me pleasure to express to your Excellency my satisfaction at the completion of this important work of peace. I am sure that I am at one with your Excellency in wishing and hoping that this cable communication will further the well-being, and will contribute to the maintenance of the friendly relations existing between our two countries. WILHELM, I.R.

President McKinley replied as follows:—

To his Majesty Emperor and King William II., Berlin.

I have received with great pleasure your Majesty's telegram of congratulation on the occasion of the inauguration of the cable, which completes the net of closer communication between this country and the German Empire. In this age of progress every tie which draws nations nearer together in their commercial and friendly relations and in their general well-being cannot fail to strengthen their cordial relations, and speed them on their mutual advance along the path of peace.

Traction Electrolysis at Providence, R.I.—Investigations have recently been carried out at Providence, R.I., to determine the danger from electrolysis due to traction earth currents, and a report has been drawn up by Mr. A. A. Knudson, of New York. Most of the electrolytic troubles are accounted for by bad bonding or broken bonds. In some cases the voltage between the tracks was as high as 5 volts. The following extract from the report gives a description of the condition of the pipes after excavation:—

At the 11 excavations made the water mains were carefully examined for evidence of electrolysis, and tests for current flow through them were made at each place. Most of them were in soil which was sandy, and in some cases hardly damp, although there had been recent rain; this condition of soil is not such as to favour the flow of current from the mains owing to its high electrical resistance, and thereby to cause electrolytic action at such points. In some cases, however, where the soil was more favourable, and the current flow in the main excessive, electrolysis pittings have been found, but not of an immediately serious nature so far as could be seen, as in all except one case the action was found on the bell end of the joint, where the metal is heavier than at other portions. The exception mentioned was at the excavation on Hartford-avenue, near the junction of Plainfield-street and Manton-avenue, where the effects of electrolysis were found at the spigot side of a joint, the current of the pipe flowing in the reverse direction in relation to the joint. This is a condition which should cause concern and warrant early attention, for although the damage is not serious, as found at this point, there may be many other joints in this main located where more favourable conditions prevail to cause electrolysis to be more active and damaging.

A Selector System of Typewriting Telegraphy.—A typewriting telegraph embodying several novel features has recently been brought out in America by Messrs. Z. G. Sholes and A. C. Gilmore of Chicago. One of the principal features of this instrument is that the signals are transmitted over an ordinary telegraph line by Morse dots and dashes. The transmitting instrument consists of a typewriter resembling an ordinary Remington-Sholes machine with an electric sending apparatus attached. This sending attachment consists of a contact drum which is driven one revolution, by a tiny electric motor, every time that a typewriter key is depressed. When a key is depressed and while the contact cylinder is making its one revolution, a contact finger corresponding to the letter struck is brought down against the cylinder. Upon the cylinder are contact strips corresponding to each letter as arranged on the Morse alphabet. The revolution of the cylinder therefore transmits the Morse signal for that letter. At the receiving end a relay is operated which works the receiving apparatus in the following manner. The impulses from the line are received by means of an electromagnetic selector apparatus which separates the several batches of signals. By means of a contact arm moving over contacts, the different combinations of dots and dashes that form each separate letter are made to operate the keys of the receiving typewriter through the agency of a number of electromagnets placed underneath the instrument. We understand that messages have been transmitted with this instrument over 265 miles of the Central Union Telephone Co.'s lines in Illinois. The speed at present attained is said to be about the same as that of an average telegraph operator. A recent issue of the *Western Electrician* of Chicago gives an illustration of this instrument together with further particulars of its construction.

Gas Polarisation in Lead Accumulators.—Messrs. Nernst & Dolezalek, commenting on this subject in the *Zeitschrift für Elektrochemie*, say that, according to the theory of the liberation of hydrogen on metals which Caspari has been recently seeking to verify experimentally (*Zeitschr. Physikal. Chem.*, 1899, Vol. XXX., p. 89), there is a term to be taken into account in addition to that which represents the energy requisite for the decomposition of the electrolyte, and this term depends on a specific property of the electrodes themselves, and is probably greater the smaller the amount of hydrogen which has to be abstracted by them. As lead has this property in a very small degree the work which is necessary for the formation of hydrogen bubbles in the electrolysis of dilute sulphuric acid is considerably greater on a lead surface than on one of platinum. Therefore, in the electrolysis of dilute sulphuric acid containing lead sulphate in solution, not hydrogen, but lead is formed. Lead sulphate immersed in dilute sulphuric acid in a platinum vessel was not reduced by a current of 0·02 ampere with a current density per square centimetre of 0·0004 ampere acting on it for a week, but it was reduced in a lead vessel. According to this the potential difference between platinum and lead peroxide is 1·60 volt, and between lead and lead peroxide is 1·92 volt. If the current density is 0·01 ampere per square centimetre, then the hydrogen is formed under such high pressure on the platinum surface that a reduction of lead sulphate takes place, and the same reasoning can be applied to the case of the separation of oxygen. This abnormal behaviour of lead also explains the sharp rise in E.M.F. which takes

Digitized by Google

place at the end of charge. During the greater part of charge the acid is saturated with lead sulphate owing to the presence of dense sulphate on the electrodes, but at the end nearly all the sulphate is used up, and what is present in solution is therefore quickly electrolysed out of it, which results in the concentration of the lead ions rapidly decreasing, with a consequent rise of E.M.F. Very soon therefore the lead solution becomes so dilute that the work requisite to separate lead from it becomes as great as that which is requisite for the separation of hydrogen from a lead surface. After this the separation of lead ceases and that of hydrogen begins, and analagous changes occur at the lead peroxide electrode. If an accumulator which has been overcharged is left at rest on open circuit the ever-present lead sulphate diffuses out of the pores of the plate, quickly reducing the E.M.F. to the normal. The high potential which is noticed at the end of charge is therefore due, according to this hypothesis, to the formation of a lead sulphate concentration couple in the accumulator. In the case of mercury the evolution of hydrogen is more difficult than in that of lead, and when a lead plate is amalgamated the evolution of hydrogen does not start till a higher potential difference is reached, and in consequence a larger part of the active material takes part in the reaction. This explains the well-known effect of the mercury salts in increasing the capacity of the cell.

An American Report on Steel Rails.—The American delegates to the International Railway Congress at Paris appointed to report for all countries, except the United States, as to the nature of rail steel, have prepared their report. Our readers are aware that America has taken the lead in the matter of using high grade steel for tramway and railway rails, and that only recently has this country begun to follow the practice. The report states that on the Continent hard steel is now universally acknowledged to be superior to soft steel for rails, as it resists better the crushing action of heavy locomotive wheel loads, and improvements in metallurgical processes now enable hard steel rails to be rolled without danger of brittleness. Both acid and basic steel are used, the latter on a large number of lines. The report refers to a remarkable case of rail wear on the Western Railway of France, where some 89lb. basic steel rails which had been in service seven years at stations, where they were subject to the braking action of the wheels, were worn down 1·06in. on the head, after carrying a traffic of 450,000 trains, without producing an uneven surface. When it is considered that the wear which rails will ordinarily stand is $\frac{1}{4}$in. to $\frac{1}{2}$in., in most cases $\frac{3}{8}$in., this record speaks well for basic steel. The report produces some evidence to show that the hardness (percentage of carbon) should be increased with increase in weight of rail, one reason stated specifically being that in light and heavy rails, made by the same process from steel showing the same tensile strength in both, the metal in the heavier rails appeared to be less homogenous and offered less resistance to wear. On the wear of rails the information produced by the report was gathered from widely varying results. For instance, on the Kaiser Ferdinand's road in Austria the average wear per 100,000 trains amounted to 0·039in., while on the Northern Railway of France the wear was 0·078in. per 100,000 trains, under similar conditions. The report as to wear on the railways of Great Britain and colonies states that information received on this subject is vague and indefinite in regard to such particulars as grades, tonnage, number of trains, &c. On the London and South-Western Railway, bull-headed rails weighing 82lb. per yard lost 15 per cent. of their weight in 15 years, while 88lb. T-rails laid in a tunnel lost 10 per cent. of their weight in nine years; the same rails under heavy traffic on open track lost 15 per cent. of their weight in five years, while rails of the same weight in a different track lost only 6 per cent. during the same time. In the practice with the railways of Great Britain and colonies most companies specify metal having an ultimate tensile strength of 40 tons to 50 tons per square inch, and in addition to this some companies specify that metal of this strength must show an elongation of 15 per cent. to 20 per cent. Acid steel is used in all cases and is made by both the open hearth and Bessemer processes, more generally by the latter. The percentages of carbon runs pretty generally from 0·35 per cent. to 0·50 per cent. Some of the companies leave the technical conditions of manufacture to the discretion of the manufacturer, stipulating that certain tests shall be made, while others exercise a considerable amount of precaution as to the handling of the metal during manufacture, specifying the minimum size of ingot, hammered and reheated ingots and the cropping of all doubtful metal from the ends of rails. On the whole the report shows some differences between European and American practice and many points of similarity. An important difference is in the use of basic steel and steel made by the open-hearth process, neither practice having as yet gained a foothold in America. On proportioning the metal between head and base and as to the preference for the use of hard steel the practice in Europe is similar to their own. Hammered ingots were once the rule in America, but the practice was abandoned many years ago.

Railways and Moving Platforms.—We reprint below a remarkable letter from Prof. John Perry which appeared in *Nature* last week. Prof. Perry claims to have invented, about 20 years ago, a method of entering and leaving moving trains, which may be regarded as containing the germ of the idea of moving platforms and stairways so recently grown popular. Although the subject is not directly electrical, our readers will readily perceive that if the scheme is to be put into practice it can only be by the application of electric power:—

About 20 years ago I was in the habit of speaking with Prof. Ayrton and other friends about a scheme which might increase ten-fold the carrying capacity of the Underground Railway. I prepared a letter for *The Times* newspaper about two years ago, but at the earnest entreaty of a friend I applied for patent protection for the scheme, and did not publish the letter. I have not proceeded with the patent, and wish now that I had published the letter. Indeed, I wish that, instead of merely talking the matter over with friends 20 years ago, I had published what I had to say. Travelling now on the new Central London Railway, one feels that there is enormous waste of energy and of time in starting and stopping the trains. Again, a train must not be longer than the platform. On my scheme the train does not stop, and the longer it is the better. Indeed, I can imagine an endless train keeping a perfectly constant speed all the time. My scheme is easy enough to understand now that moving platforms are common. After passengers enter a station I get them gradually into a state of motion, so that moving alongside the train, and at the same speed, they may enter and other passengers may leave. There are many ways in which the scheme may be carried out. From a wayside station passengers may enter an express train which does not stop in the following way: They enter a small train at the station; this train gradually gets up a speed equal to that of the express; it runs alongside the express at a particularly well-laid part of the line; there is an exchange of passengers, and the local train gradually comes to rest again at the station. For the Underground Railway the method which most commended itself to Prof. Ayrton and me long ago was this: At a station, say St. James's Park, the platform was a carefully contructed turntable, 500ft. in diameter, the rim of which travelled at 8 miles per hour. The whole area was not really a floor; it was only a skeleton of a turntable, being an outer rim 8ft. broad and many radial passages. The very long train to Mansion House, travelling at 8 miles per hour, was close to the rim of the turntable; indeed geared with it in a rough, simple manner for less than half its circumference; the train from Mansion House did the same on the other side. I need not speak of the automatic opening and closing of the doors of the train. A passenger—let us say second class for Mansion House, takes his ticket and descends a spiral staircase, which revolves so slowly that even the frailest and most timid of old ladies is not frightened; in fact, it revolves on its own axis once in 134 seconds. At the bottom the passenger sees a few notices; one of them saying second class, Mansion House, has a hand pointing along a radial passage, and this is followed. As the passenger moves radially, he does not notice that he is gradually getting up speed circumferentially. He does not notice that the floor gets slightly inclined as he moves out, to counteract the small effect of centrifugal force. When he reaches the outside of the platform he probably finds a train there, seemingly at rest, with the doors open, and he enters it, moving perhaps along the platform, choosing one compartment rather than another. If he is lucky he has about one minute in which to make his choice. But he will notice near him on the platform an altering time signal which tells him how much more time he has to waste: 50sec., 40sec. or 30sec., or 20sec., or 10sec. If he delays after the signal says 0, an iron railing will come between him and the train; he will see the train moving laterally away from the platform, and he must wait 74sec. before he sees a train coming laterally towards him; the railing goes away, and he has again 60sec. in which to enter. If he had a third-class to South Kensington, he would have proceeded in exactly the same way. Also every passenger wanting to leave the train at St. James's Park had 60sec. in which to do it. Trains at 16 miles an hour would give only half these times. A platform of only 250ft. diameter would give only half the time if the train speed was 8 miles an hour. I need not dwell upon the details of this and other methods which suggest themselves. It may be soon or syne, but I feel sure—I have felt sure for many years—that my method will have to be adopted.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Spectrum of Radium.—Demarçay has given a list of 15 spectrum lines due to "radium." C. Runge points out, however, that the accuracy of Demarçay's determinations is not very great, the error being about 0·7 of an Angström unit. Hence Demarçay's line 4,688·0 might be anywhere between 4,682·3 and 4,688·7. But in this interval there are no less than six Fraunhofer lines, according to Rowland, and that makes the evidence for the separate identity of radium very much feebler than it was. Runge has therefore re-determined the spectrum of radio-active barium chloride with a greater dispersive power than that employed by Demarçay, and has been able to definitely locate three of Demarçay's lines. These are situated at 4,826·14, 4,682·346, and 3,814·591 respectively. The remainder were either invisible, or were found in the spectrum of barium chloride when free from radium. An economical method of spectroscopy was that of dipping a thin platinum wire into the powdered preparation and heating the wire by means of an electric current until a bead was formed, which was then made an anode in a spark-gap. But it is possible that the luminous intensity attained was not great enough to reveal some of the feebler lines described by Demarçay. In any case, the existence of at least three characteristic lines may be taken as definitely proved. They are not contained in the solar spectrum.

[C. Runge, *Ann. der Physik*, No. 8, 1900.]

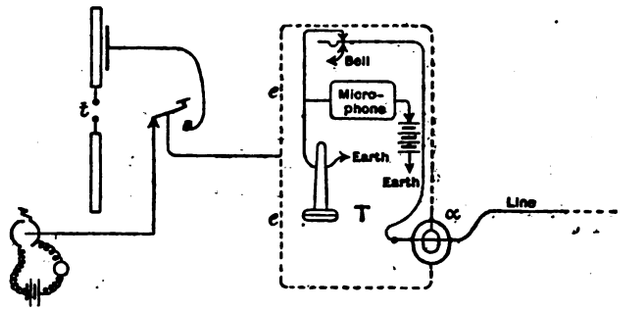
Atomic Weight of Radium.—Madame Curie has made considerable progress lately towards the eventual isolation of pure radium. The latest product only contains traces of barium, and may be regarded as practically pure radium chloride. But the quantity of the salt so far available is too small to determine the atomic weight of radium from it, and the authoress has had to content herself with a determination of the atomic weight of the mixed metallic base contained in a product rich in radium. The atomic weight of pure barium is 137·5. The value for the mixed product found last November was 146, and the latest value is 174. The two last figures mark the very considerable advance made in the last half-year towards the purification of the radium salt. How high the atomic weight of radium is cannot at present be even guessed at, since there is no means of determining the proportion of radium in the salt, and the spectroscope only yields very rough quantitative indications. But it is safe to say that it is very high. Radio-activity seems, in fact, to be conditioned by a high atomic weight, just as if the heavier atoms had more negative electrons to spare. It is to be hoped that, in spite of the difficulty and costliness of the work involved, the atomic weight of radium will soon be obtained from the pure chloride.

[Madame Curie, *Comptes Rendus*, August 6, 1900.]

Circuit of Electrolytes.—Electrolysis without electrodes has already been satisfactorily carried out by means of liquid electrolytes moving in a magnetic field. Camichel and Swyngedauw now describe some new arrangements, one of which proves that an electrolyte can be traversed by a current without any electrolysis taking place, or at least none which involves the evolution of gas. The authors induced an alternating current in an electrolytic circuit (acidulated water of density 1·25) contained in a glass tube, under conditions in which a voltameter should have given several cubic centimetres of gas, but none was produced. In another experiment, a spiral tube of ebonite was wound about the primary coil of a transformer and inside the secondary coil, and the circuit was completed by means of a glass tube, the whole having a resistance of some 70 ohms. A constantan-iron thermo-couple indicated a rise of temperature of the order which could be expected in consideration of the experimental data. The authors also formed an electrolytic chain consisting of sulphuric acid, sodium chloride, and potash, separated presumably by porous partitions. The contact surfaces were renewed by continuous circulation. But the sensitiveness of the galvanometer employed was not sufficient to place in evidence the current probably generated.

[Camichel and Swyngedauw, *Comptes Rendus*, August 6, 1900.]

Simultaneous Telegraphy and Telephony.—A. Turpain has devised a means of utilising a telephone circuit for the transmission of simultaneous telegraphic messages by employing wire waves generated by a Lecher oscillator. The main difficulty employed lies in protecting the telephone circuit from the effect of the waves. This is done by enclosing the telephone apparatus T (see diagram) in a cabin papered with



tinfoil *e*. The line wire traverses a vacuum tube inserted in the wall. It is surrounded by a wire ring not in contact with it, but in touch with the tinfoil. This tinfoil is connected with the resonator *t*. It captures the waves and thus leaves the telephone undisturbed.

[A. Turpain, *Journ. de Physique*, August, 1900.]

Measurement of Electric Absorption.—Rowland has described an arrangement for measuring the residual charge of a condenser, or what is now generally termed electric absorption, consisting essentially of a Wheatstone bridge, in which the fixed coils of an electrodynamometer are placed in one arm of the bridge and the hanging-coil in the cross-connection, where the galvanometer is ordinarily inserted. The adjustment of the bridge thus used depends upon the fact that there will be no deflection of the electrodynamometer if the phase-difference of the current in the fixed coils and those in the hanging-coil is 90deg. L. M. Potts has tested this method and found it very satisfactory. The electric absorption always acts as a resistance in series with a capacity. This resistance is independent of the current. The temperature has a decided effect, the absorption increasing very rapidly with rising temperature. Both the capacity and the resistance depend upon the period of the current. The method is very useful for determining the capacity of a condenser showing electric absorption. The method given by Rowland for the detection of short circuits in coils proves to be an exceedingly sensitive one, and his method for the measurement of losses due to hysteresis and Foucault currents gives very good results, its chief advantage lying in the fact that only small quantities—say a few hundred grammes—of the substance are necessary.

[L. M. Potts, *Am. Journ. of Science*, August, 1900.]

Electrification by Ice.—In the course of some experiments on liquid air, H. Ebert and B. A. Hoffmann noticed that a body suspended above the surface of the liquid acquired a strong negative charge. A series of test experiments revealed the fact that this charge is not due to the liquid air itself, but to the friction of minute particles of very cold ice suspended in it. The authors even succeeded in constructing a kind of electrifying machine by means of a tube containing a piece of wire gauze through which the vapour of liquid air was driven. This phenomenon of electrification should be allowed for in all experiments with liquid air, as it may account for many errors and anomalies. Ice acquires a positive charge by friction with any metal, and imparts to the metal, and other bodies also, a negative charge. It appears to be the more active in this respect, the colder and the drier it is. This may account for the strong electric effects of polar snowstorms. Even in our latitudes, ascending currents of air soon reach elevations at which all their water freezes, and the friction of the ice crystals against suspended dust particles would account for part of the atmospheric electrification. In the highest regions, a friction between atmospheric ice and cosmic dust, together with solar ionisation and the consequent conductivity of the atmosphere, might account for the luminescence often observed, and even for the aurora.

THE CENTRAL LONDON RAILWAY.

(*Continued from page 557.*)

In our last article we brought to a conclusion our description of the power station and its equipment. We have now to consider the means for the transmission of power to the various sub-stations, and afterwards its distribution along the line.

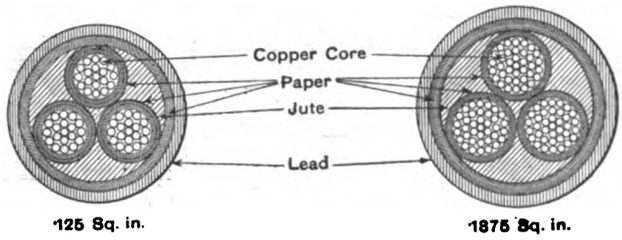

FIG. 35.—SECTION OF HIGH-PRESSURE CABLES.

Three-phase Feeders.—The 5,000-volt three-phase current is conducted from the power station through four independent

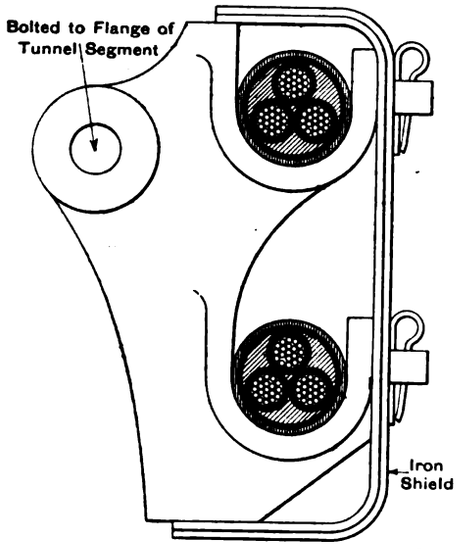

FIG. 36.—SECTION OF CABLE SUPPORT AND SHIELD.

feeders. These are three-core, paper insulated, lead-covered cables (Fig. 35), tested to 15,000 volts, and also to one hour's

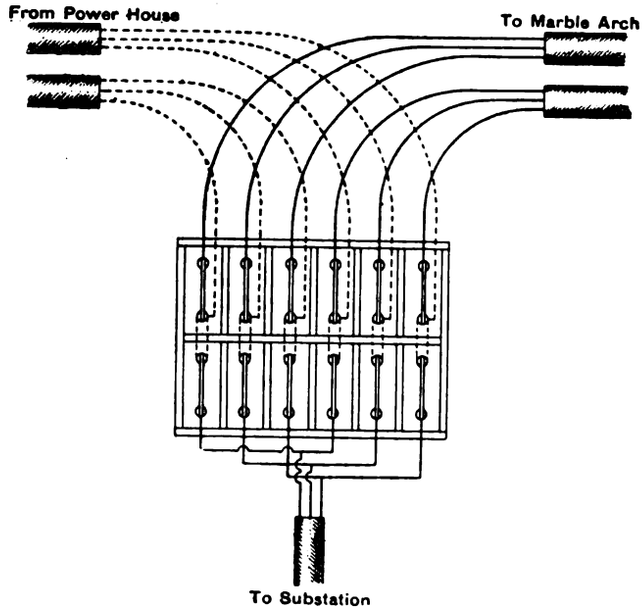

FIG. 37.—ONE OF THE HIGH-PRESSURE CONNECTION BOXES AT NOTTING HILL GATE STATION.

10,000 volts test—firstly, between the different cores, and subsequently from the cores to earth. Capacity tests have been made as follows, the figures giving the capacity per mile: Between one core and the other two cores and the sheathing, 0·88 microfarads; between one core and the other two cores alone, 0·82 microfarads; and between one core and one other core, 0·23 microfarads. The cables are conveyed in a special tunnel together with the test cables, &c., to the

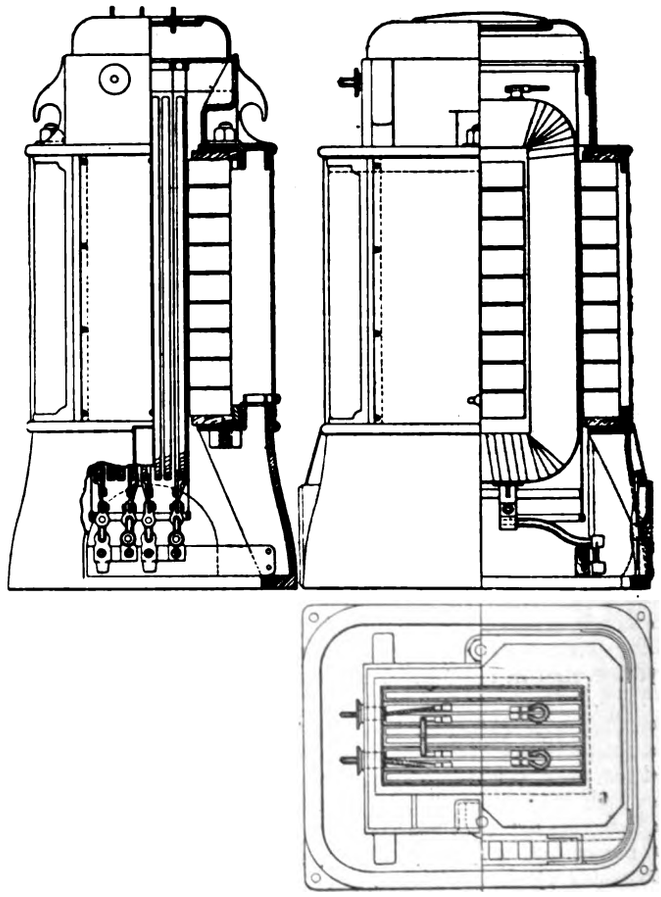

FIG. 38.—ONE OF THE 300KW. TRANSFORMERS.

entrance of the railway tunnel, where they are brought down to the side of the tunnel and carried on brackets protected by sheet-iron shields, as shown in Fig. 36. Two cables are in the down tunnel and two in the up tunnel. At Notting Hill Gate station, where the first sub-station is erected, there is a small brick chamber in each tunnel within which is mounted

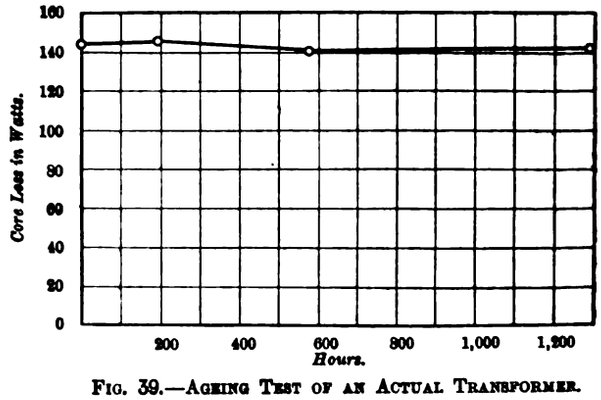

FIG. 39.—AGEING TEST OF AN ACTUAL TRANSFORMER.
The temperature of the core was maintained at 80° C. during the test.

a marble connection box, shown in Fig. 37. Here three 37/16 cables are carried from the three cores of each of the four cables to the sub-station. By means of this small switchboard one or more of the four cables can be cut out of service, or

Digitized by Google

an entire sub-station can be completely cut off from the three-phase system. From the power-house to the Notting Hill Gate station each three-phase feeder has a total copper section of

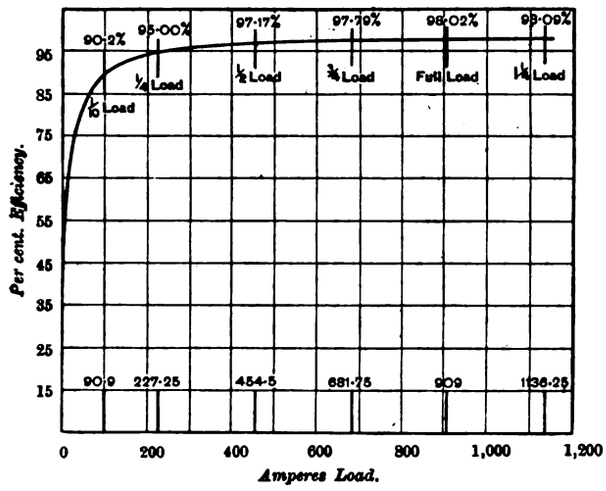

FIG. 40.—EFFICIENCY CURVE OF TRANSFORMER.

0·1875 sq. in., but from the Notting Hill Gate station to the Marble Arch sub-station the cross section is reduced to 0·125 sq. in. Only two cables—viz., one in each tunnel, is

5,000 volts, 400 amperes. Scale: One-twelfth full size.

Equipment of the Sub-stations.—Although the actual arrangement of the plant differs at the various sub-stations to suit the local circumstances, the equipment of each sub-station is the same. It will be unnecessary, therefore, to describe

Digitized by Google

more than one of these stations. Our illustrations, where they differ from the general arrangements, relate to the Notting Hill Gate station. Each station is provided with seven stationary transformers each of 800kw. capacity, two rotatory converters each of 900kw. capacity and two blower sets. There is also, of course, a switchboard for controlling the three-phase and continuous-current connections.

The static transformers, one of which is shown in Fig. 38, have their primaries wound for 5,000 volts and their secondary coils for 330 volts. By means of the blowers, to be described presently, a forced circulation of air is maintained around and through the coils, vertically through the cells and horizontally through the armature laminations. The primaries of the transformers are connected in delta arrangement to the three-phase circuit. The core is built up of laminated iron 0·014in. thick, arranged horizontally, and forming a double magnetic circuit round the coils; each sheet is japanned separately to reduce the eddy current losses to a minimum. The iron used is of a special quality, having high permeability and low hysteresis loss, and is not subject to deterioration due to ageing. A curve showing the actual ageing is given in Fig. 39. Ventilating ducts are left between the laminations at intervals of a few inches. The coils, which are form-wound, are arranged vertically, there being four primary and four secondary sections. Earth shields are placed between the primary and secondary sections, and ventilating ducts are left to admit of the maximum cooling surface for the coils. The method of cooling by forced ventilation consists in drawing air through the transformer by means of blowers. The ventilation can be regulated by means of adjustable dampers situated at the top and side of the transformer case. The case of each transformer is connected through the base to an air chamber running under the bank of transformers, and the air from this is exhausted by means of two blowers furnished by the Buffalo Forge Co., and driven by three-phase 6 H.P. induction motors having squirrel cage armatures. Either or both blower sets can be used, but one is sufficient for ordinary need, the other being held in reserve. Figs. 40 to 43 give characteristic curves for the transformers, showing efficiency, losses, impedance, and core loss, &c. Both primary and secondary coils of the transformers are connected to double pole switches on the switchboard, so that any or all of the transformers may be used as circumstances require. Fig. 44 shows the three-phase oil switch.

(To be continued.)

The Electric Equipment of the New York Elevated Railways.—Mr. W. E. Baker, the superintendent of the electric construction of the Manhattan Railway of New York has announced that the first electrically-equipped train may be expected to run on this railway about the 15th inst. The first section to be completely equipped is the Second Avenue line, on account of its proximity to the power station. The total capacity of the new power station will be 64,000 H.P., and the maximum horse-power, exclusive of storage plant, which will be erected at the sub-stations, will aggregate 100,000 H.P. Each train will be equipped with four 100 H.P. motors.

DR. JOSEPH LARMOR'S PRESIDENTIAL ADDRESS TO A SECTION OF THE BRITISH ASSOCIATION AT BRADFORD.*

It is fitting that before entering upon the business of the Section we should pause to take note of the losses which our department of science has recently sustained. The fame of Bertrand, apart from his official position as secretary of the French Academy of Sciences, was long ago universally established by his classical treatise on the "Infiniteaimal Calculus": it has been of late years sustained by the luminous exposition and searching criticism of his books on the "Theory of Probability and Thermodynamics and Electricity." The debt which we owe to that other veteran, G. Wiedemann, both on account of his own researches, which take us back to the modern revival of experimental physics, and for his great and indispensable thesaurus of the science of electricity, cannot easily be overstated. By the death of Sophus Lie, following soon after his return to a chair in his native country Norway, we have lost one of the great constructive mathematicians of the century, who has in various directions fundamentally expanded the methods and conceptions of analysis by reverting to the fountain of direct geometrical intuition. In Italy the death of Beltrami has removed an investigator whose influence has been equally marked on the theories of transcendental geometry and on the progress of mathematical physics. In our own country we have lost in D. E. Hughes one of the great scientific inventors of the age; while we specially deplore the removal, in his early prime, of one who has recently been well known at these meetings, Thomas Preston, whose experimental investigations on the relations between magnetism and light, combined with his great powers of lucid exposition, marked out for him a brilliant future.

Perhaps the most important event of general scientific interest during the past year has been the definite undertaking of the great task of the international co-ordination of scientific literature, and it may be in some measure in the prolonged conferences that were necessitated by that object that the recently announced international federation of scientific academies has had its origin. In the important task of rendering accessible the stores of scientific knowledge the British Association, and in particular this section of it, has played the part of pioneer. Our annual volumes have long been classical, through the splendid reports of the progress of the different branches of knowledge that have been from time to time contributed to them by the foremost British men of science, and our work in this direction has received the compliment of successful imitation by the sister associations on the Continent. The usual conferences connected with our department of scientific activity have been this year notably augmented by the very successful international congresses of mathematicians and of physicists which met a few weeks ago in Paris. The three volumes of reports on the progress of physical science during the last 10 years, for which we are indebted to the initiative of the French Physical Society, will provide an admirable conspectus of the present trend of activity, and form a permanent record for the history of our subject. Another very powerful auxiliary to progress is now being rapidly provided by the republication, in suitable form and within reasonable time, of the collected works of the masters of our science. We have quite recently received, in a large quarto volume, the mass of most important unpublished work that was left behind him by the late Prof. J. C. Adams; the zealous care of Prof. Sampson has worked up into order the more pure astronomical part of the volume; while the great undertaking, spread over many years, of the complete determination of the secular change of the magnetic condition of the earth, for which the practical preparations had been set on foot by Gauss himself, has been prepared for the press by Prof. W. G. Adams. By the publication of the first volume of Lord Rayleigh's papers a series of memoirs which have formed a main stimulus to the progress of mathematical physics in this country during the past 20 years has become generally accessible. The completed series will form a landmark for the end of the century that may be compared with Young's "Lectures on Natural Philosophy" for its beginning.

The recent reconstruction of the University of London, and the foundation of the University of Birmingham, will, it is to be hoped, give greater freedom to the work of our University Colleges. The system of examinations has formed an admirable stimulus to the effective acquisition of that general knowledge which is a necessary part of all education. So long as the examiner recognises that his function is a responsible and influential one, which is to be taken seriously from the point of view of moulding the teaching in places where external guidance is helpful, test by examination will remain a most valuable means of extending the area of higher education. Except for workers in rapidly progressive branches of technical science, a broad education seems better adapted to the purposes of life than special training over a narrow range; and it is difficult to see how a reasonably elastic examination test can be considered

* Delivered Sept. 6, 1900.

Digitized by Google

as a hardship. But the case is changed when preparation for a specialised scientific profession, or mastery of the lines of attack in an unsolved problem, is the object. The general education has then been presumably finished; in expanding departments of knowledge, variety rather than uniformity of training should be the aim, and the genius of a great teacher should be allowed free play without external trammels. It would appear that in this country we have recently been liable to unduly mix up two methods. We have been starting students on the special and lengthy, though very instructive, processes which are known as original research at an age when their time would be more profitably employed in rapidly acquiring a broad basis of knowledge. As a result we have been extending the examination test from the general knowledge to which it is admirably suited into the specialised activity which is best left to the stimulus of personal interest. Informal contact with competent advisers, themselves imbued with the scientific spirit, who can point the way towards direct appreciation of the works of the masters of the science, is far more effective than detailed instruction at second hand as regards growing subjects that have not yet taken on an authoritative form of exposition. Fortunately there seems to be now no lack of such teachers to meet the requirements of the technical colleges that are being established throughout the country.

The famous treatise which opened the modern era by treating magnetism and electricity on a scientific basis appeared just 300 years ago. The author (William Gilbert, M.D., of Colchester) passed from the Grammar School of his native town to St. John's College, Cambridge; soon after taking his first degree, in 1560, he became a Fellow of the College, and seems to have remained in residence, and taken part in its affairs for about 10 years. All through his subsequent career, both at Colchester and afterwards at London, where he attained the highest position in his profession, he was an exact and diligent explorer, first of chemical and then of magnetic and electric phenomena. In the words of the historian Hallam, writing in 1839, "in his Latin treatise on the Magnet he not only collected all the knowledge which others had possessed, but he became at once the father of experimental philosophy in this island"; and no demur would be raised if Hallam's restriction to this country were removed. Working nearly a century before the time when the astronomical discoveries of Newton had originated the idea of attraction at a distance, he established a complete formulation of the interaction of magnets by what we now call the exploration of their fields of force. His analysis of the facts of magnetic influence, and incidentally of the points in which it differs from electric influence, is virtually the one which Faraday re-introduced. A cardinal advance was achieved, at a time when the Copernican Astronomy had still largely to make its way, by assigning the behaviour of the compass and the dip needle to the fact that the earth itself is a great magnet, by whose field of influence they are controlled. His book passed through many editions on the Continent within 40 years: it won the high praise of Galileo. Gilbert has been called "the father of modern electricity" by Priestley, and "the Galileo of magnetism" by Poggendorff.

When the British Association last met at Bradford in 1873 the modern theory which largely reverts to Gilbert's way of formulation, and refers electric and magnetic phenomena to the activity of the æther instead of attractions at a distance, was of recent growth: it had received its classical exposition only two years before by the publication of Clerk Maxwell's treatise. The new doctrine was already widely received in England on its own independent merits. On the Continent it was engaging the strenuous attention of Helmholtz, whose series of memoirs, deeply probing the new ideas in their relation to the prevalent and fairly successful theories of direct action across space, had begun to appear in 1870. During many years the search for crucial experiments that would go beyond the results equally explained by both views met with small success; it was not until 1887 that Hertz, by the discovery of the æthereal radiation of long wave-length emitted from electric oscillators, verified the hypothesis of Faraday and Maxwell and initiated a new era in the practical development of physical science. The experimental field thus opened up was soon fully occupied both in this country and abroad; and the borderland between the sciences of optics and electricity is now being rapidly explored. The extension of experimental knowledge was simultaneous with increased attention to directness of explanation; the expositions of Heaviside and Hertz and other writers fixed attention, in a manner already briefly exemplified by Maxwell himself, on the inherent simplicity of the completed æthereal scheme, when once the theoretical scaffolding employed in its construction and dynamical consolidation is removed; while Poynting's beautiful corollary specifying the path of the transmission of energy through the æther has brought the theory into simple relations with the applications of electrodynamics. Equally striking has been the great mastery obtained during the last 20 years over the practical manipulation of electric power. The installation of electric wires as the nerves connecting different regions of the earth had attained the rank of accomplised fact so long ago as 1857, when the first Atlantic cable was laid. It was largely the theoretical and practical difficulties, many of them unforeseen, encountered in carrying that great undertaking to a successful issue, that necessitated the elaboration by Lord Kelvin and his coadjutors of convenient methods and instruments for the exact measurement of electric quantities, and thus prepared the foundation for the more recent practical developments in other directions. On the other hand, the methods of theoretical explanation have been in turn improved and simplified through the new ways of considering the phenomena which have been evolved in the course of practical advances on a large scale, such as the improvement of dynamo armatures, the conception and utilisation of magnetic circuits, and the transmission of power by alternating currents. In our time the relations of civilised life have been already perhaps more profoundly altered than ever before, owing to the establishment of practically instantaneous electric communication between all parts of the world. The employment of the same subtle agency is now rapidly superseding the artificial reciprocating engines and other contrivances for the manipulation of mechanical power that were introduced with the employment of steam. The possibilities of transmitting power to great distances at enormous tension, and therefore with very slight waste, along lines merely suspended in the air, are being practically realised; and the advantages thence derived are increased manifold by the almost automatic manner in which the electric power can be transformed into mechanical rotation at the very point where it is desired to apply it. The energy is transmitted at such lightning speed that at a given instant only an exceedingly minute portion of it is in actual transit. When the tension of the alternations is high, the amount of electricity that has to oscillate backwards and forwards on the guiding wires is proportionately diminished, and the frictional waste reduced. At the terminals the direct transmission from one armature of the motor to the other, across the intervening empty space, at once takes us beyond the province of the pushing and rubbing contacts that are unavoidable in mechanical transmission; while the perfect symmetry and reversibility of the arrangement by which power is delivered from a rotatory alternator at one end, guided by the wires to another place many miles away, where it is absorbed by another alternator with precise reversal of the initial stages, make this process of distribution of energy resemble the automatic operations of nature rather than the imperfect material connections previously in use. We are here dealing primarily with the flawless continuous medium which is the transmitter of radiant energy across the celestial spaces; the part played by the coarsely-constituted material conductor is only that of a more or less imperfect guide which directs the current of æthereal energy. The wonderful nature of this theoretically perfect, though of course practically only approximate, method of abolishing limitations of locality with regard to mechanical power is not diminished by the circumstance that its principle must have been in some manner present to the mind of the first person who fully realised the character of the reversibility of a gramme armature.

In theoretical knowledge a new domain, to which the theory as expounded 20 years ago had little to say, has recently been acquired through the experimental scrutiny of the electric discharge in rarefied gaseous media. The very varied electric phenomena of vacuum tubes, whose electrolytic character was first practically established by Schuster, have been largely reduced to order through the employment of the high exhaustions introduced and first utilised by Crookes. Their study under these circumstances, in which the material molecules are so sparsely distributed as but rarely to interfere with each other, has conduced to enlarged knowledge and verification of the fundamental relations in which the individual molecules stand to all electric phenomena, culminating recently in the actually determination, by J. J. Thomson and others following in his track, of the masses and velocities of the particles that carry the electric discharge across the exhausted space. The recent investigations of the circumstances of the electric dissociation produced in the atmosphere and in other gases by ultra-violet light, the Röntgen radiation, and other agencies, constitute one of the most striking developments in experimental molecular physics since Graham determined the molecular relations of gaseous diffusion and transpiration more than half a century ago. This advance in experimental knowledge of molecular phenomena, assisted by the discovery of the precise and rational effect of magnetism on the spectrum, has brought into prominence a modification or rather development of Maxwell's exposition of electric theory, which was dictated primarily by the requirements of the abstract theory itself; the atoms or ions are now definitely introduced as the carriers of those electric charges which interact across the æther, and so produce the electric fields whose transformations were the main subject of the original theory. We are thus inevitably led, in electric and æthereal theory, as in the chemistry and dynamics of the gaseous state, which is the department of abstract physics next in order of simplicity, to the consideration of the individual molecules of matter. The theoretical problems which had come clearly into view a quarter of a century ago, under Maxwell's lead, whether in the exact dynamical relations of æthereal transmission or in the more fortuitous domain of the statistics of

Digitized by Google

interacting molecules, are those around which attention is still mainly concentrated; but as the result of the progress in each, they are now tending towards consolidation into one subject. I propose—leaving further review of the scientific aspect of the recent enormous development of the applications of physical science for hands more competent to deal with the practical side of that subject—to offer some remarks on the scope and validity of this molecular order of ideas, to which the trend of physical explanation and development is now setting in so pronounced a manner.

If it is necessary to offer an apology for detaining the attention of the section on so abstract a topic, I can plead its intrinsic philsophical importance. The hesitation so long felt on the Continent in regard to discarding the highly developed theories which analysed all physical actions into direct attractions between the separate elements of the bodies concerned, in favour of a new method in which our ideas are carried into regions deeper than the phenomena, has no given place to eager discussion of the potentialities of the new standpoint. There has even appeared a disposition to consider that the Newtonian dynamical principles, which have formed the basis of physical explanation for nearly two centuries, must be replaced in these deeper subjects by a method of direct description of the mere course of phenomena, apart from any attempt to establish casual relations, the initiation of this method being traced, like that of the Newtonian dynamics itself, to this country. The question has as to how far the new methods of æthereal physics are to be considered as an independent departure, how far they form the natural development of existing dynamical science. In England, whence the innovation came, it is the more conservative position that has all along been occupied. Maxwell was himself trained in the school of physics established in this country by Sir George Stokes and Lord Kelvin, in which the dominating idea has been that of the strictly dynamical foundation of all physical action. Although the pupil's imagination bridged over dynamical chasms, across which the master was not always able to follow, yet the most striking feature of Maxwell's scheme was still the dynamical framework into which it was built. The more advanced reformers have now thrown overboard the apparatus of potential functions which Maxwell found necessary for the dynamical consolidation of his theory, retaining only the final result as a verified descriptive basis for the phenomena. In this way all difficulties relating to dynamical development and, indeed, consistency are avoided, but the question remains as to how much is thereby lost. In practical electromagnetics the transmission of power is now the most prominent phenomenon. If formal dynamics is put aside in the general theory its guidance must here be replaced by some more empirical and tentative method of describing the course of the transmission and transformation of mechanical energy in the system.

The direct recognition in some form, either explicitly or tacitly, of the part played by the æther has become indispensable to the development and exposition of general physics ever since the discoveries of Hertz left no further room for doubt that this physical scheme of Maxwell was not merely a brilliant speculation, but constituted, in spite of outstanding gaps and difficulties, a real formulation of the underlying unity in physical dynamics. The domain of abstract physics is in fact roughly divisible into two regions. In one of them we are mainly concerned with interactions between one portion of matter and another portion occupying a different position in space; such interactions have very uniform and comparatively simple relations; and the reason is traceable to the simple and uniform constitution of the intervening medium in which they have their seat. The other province is that in which the distribution of the material molecules comes into account. Setting aside the ordinary dynamics of matter in bulk, which is founded on the uniformity of the properties of the bodies concerned and their experimental determination, we must assign to this region all phenomena which are concerned with the uncoordinated motions of the molecules, including the range of thermal and in part of radiant actions; the only possible basis for detailed theory is the statistical dynamics of the distribution of the molecules. The far more deep-seated and mysterious processes which are involved in changes in the constitution of the individual molecules themselves are mainly outside the province of physics, which is competent to reason only about permanent material systems; they must be left to the sciences of chemistry and physiology. Yet the chemist proclaims that he can determine only the results of his reactions and the physical conditions under which they occur; the character of the bonds which hold atoms in their chemical combinations is at present unknown, although a large domain of very precise knowlege relating, in some diagrammatic manner, to the topography of the more complex molecules has been attained. The vast structure which chemical science has in this way raised on the narrow foundation of the atomic theory is perhaps the most wonderful existing illustration both of the rationality of natural processes and of the analytical powers of the human mind. In a word, the complication of the material world is referable to the vast range of structure and of states of aggregation in the material atoms; while the possibility of a science of physics is largely due to the simplicity of constitution of the universal medium through which the individual atoms interact on each other.

The reference of the uniformity in the interactions at a distance between material bodies to the part played by the æther is a step towards the elimination of extraneous and random hypotheses about laws of attraction between atoms. It also places that medium on a different basis from matter, in that its mode of activity is simple and regular, whereas intimate material interactions must be of illimitable complexity. This gives strong ground for the view that we should not be tempted towards explaining the simple group of relations which have been found to define the activity of the æther, by treating them as mechanical consequences of concealed structure in that medium; we should rather rest satisfied with having attained to their exact dynamical correlation, just as geometry explores or correlates, without explaining, the descriptive and metric properties of space. On the other hand, a view is upheld which considers the pressures and thrusts of the engineer, and the strains and stresses in the material structures by which he transmits them from one place to another, to be the archetype of the processes by which all mechanical effect is transmitted in nature. This doctrine implies an expectation that we may ultimately discover something analogous to structure in the celestial spaces, by means of which the transmission of physical effect will be brought into line with the transmission of mechanical effect by material framework.

At a time when the only definitively ascertained function of the æther was the undulatory propagation of radiant energy across space Lord Kelvin pointed out that, by reason of the very great velocity of propagation, the density of the radiant energy in the medium at any place must be extremely small in comparion with the amount of energy that is transmitted in a second of time. This easily led him to the very striking conclusion that, on the hypothesis that the æther is like material elastic media, it is not necessary to assume its density to be more than 10^{-18} of that of water, or its optical rigidity to be more than ten 10^{-8} of that of steel or glass. Thus far the æther would be merely an impalpable material atmosphere for the transference of energy by radiation, at extremely small densities but with very great speed, while ordinary matter would be the seat of practically all this energy. But this way of explaining the absence of sensible influence of the æther on the phenomena of material dynamics lost much of its basis as soon as it was recognised that the same medium must be the receptacle of very high densities of energy in the electric fields around currents and magnets.* The other mode of explanation is to consider the æther to be of the very essence of all physical actions, and to correlate the absence of obvious mechanical evidence of its intervention with its regularity and universality.

On this plan of making the æther the essential factor in the transformation of energy as well as its transmission across space, the material atom must be some kind of permanent nucleus that retains around itself an æthereal field of physical influence, such as, for example, a field of strain. We can recognise the atom only through its interactions with other atoms that are so far away from it as to be practically independent systems; thus our direct knowledge of the atom will be confined to this field of force which belongs to it. Just as the exploration of the distant field of magnetic influence of a steel magnet, itself concealed from view, cannot tell us anything about the magnet except the amount and direction of its moment, so a practically complete knowledge of the field of physical influence of an atom might be expressible in terms of the numerical values of a limited number of physical moments associated with it, without any revelation as to its essential structure or constitution being involved. This will, at any rate, be the case for ultimate atoms if, as is most likely, the distances at which they are kept apart are large compared with the diameters of the atomic nuclei; it, in fact, forms our only chance for penetrating to definite dynamical views of molecular structure. So long as we cannot isolate a single molecule, but must deal observationally with an innumerable distribution of them even this kind of knowledge will be largely confined to average values. But the last half-century has witnessed the successful application of a new instrument of research, which has removed in various directions the limitations that had previously been placed on the knowledge to which it was possible for human effort to look forward. The spectroscope has created a new astronomy by revealing the constitutions and the unseen internal motions of the stars. Its power lies in the fact that it does take hold of the internal relations of the individual molecule of matter, and provide a very definite and detailed, though far from complete, analysis of the vibratory motions that are going on in it; these vibrations being in

* We can here only allude to Lord Kelvin's recent most interesting mechanical illustrations of a solid æther interacting with material molecules and with itself by attraction at a distance; unlike the generalised dynamical method expounded in the text, which can leave the intimate structure of the material molecule outside the problem, a definite working constitution is there assigned to the molecular nucleus. It is pointed out in a continuation that is to appear in the *Phil. Mag.* for September, that a density of æther of the order of only 10^{-9}, which would not appreciably affect the inertia of matter, would involve rigidity comparable with that of steel, and thus permit transmission of magnetic forces by stress; this solid æther is, however, as usual, taken to be freely permeable to the molecules of matter.

Digitized by Google

their normal state characteristic of its dynamical constitution, and in their deviations from the normal giving indications of the velocity of its movement and the physical state of its environment. Maxwell long ago laid emphasis on the fact that a physical atomic theory is not competent even to contemplate the vast mass of potentialities and correlations of the past and the future, that biological theory has to consider as latent in a single organic germ containing at most only a few million molecules. On our present view we can accept his position that the properties of such a body cannot be those of a "purely material system," provided, however, we restrict this phrase to apply to physical properties as here defined. But an exhaustive discovery of the intimate nature of the atom is beyond the scope of physics; questions as to whether it must not necessarily involve in itself some image of the complexity of the organic structures of which it can form a correlated part must remain a subject of speculation outside the domain of that science. It might be held that this conception of discrete atoms and continuous æther really stands, like those of space and time, in intimate relation with our modes of mental apprehension, into which any consistent picture of the external world must of necessity be fitted. In any case it would involve abandonment of all the successful traditions of our subject if we ceased to hold that our analysis can be formulated in a consistent and complete manner, so far as it goes, without being necessarily an exhaustive account of phenomena that are beyond our range of experiment. Such phenomena may be more closely defined as those connected with the processes of intimate combination of the molecules: they include the activities of organic beings, which all seem to depend on change of molecular structure.

If, then, we have so small a hold on the intimate nature of matter, it will appear all the more striking that physicists have been able precisely to divine the mode of operation of the intangible æther, and to some extent explore in it the fields of physical influence of the molecules. On consideration we recognise that this knowledge of fundamental physical interaction has been reached by a comparative process. The mechanism of the propagation of light could never have been studied in the free æther of space alone. It was possible, however, to determine the way in which the characteristics of optical propagation are modified, but not wholly transformed, when it takes place in a transparent material body instead of empty space. The change, in fact, arises on account of the æther being entangled with the network of material molecules; but inasmuch as the length of a single wave of radiation covers thousands of these molecules the wave-motion still remains uniform and does not lose its general type. A wider variation of the experimental conditions has been provided for our examination in the case of those substances in which the phenomenon of double refraction pointed to a change of the æthereal properties which varied in different directions; and minute study of this modification has proved sufficient to guide to a consistent appreciation of the nature of this change, and therefore of the mode of æthereal propagation that is thus altered. In the same way, it was the study and development of the manner in which the laws of electric phenomena in material bodies had been unravelled by Ampère and Faraday, that guided Faraday himself and Maxwell—who were impressed with the view that the æther was at the bottom of it all—in their progress towards an application of similar laws to æther devoid of matter, such as would complete a scheme of continuous action by consistently interconnecting the material bodies and banishing all untraced interaction across empty space. Maxwell, in fact, chose to finally expound the theory by ascribing to the æther of free space a dielectric constant and a magnetic constant of the same types as had been found to express the properties of material media, thus extending the seat of the phenomena to all space on the plan of describing the activity of the æther in terms of the ordinary electric ideas. The converse mode of development, starting with the free æther under the directly dynamical form which has been used in physical optics, and introducing the influence of the material atoms through the electric charges which are involved in their constitution,* was hardly employed by him; in part, perhaps, because, owing to the necessity of correlating his theory with existing electric knowledge and the mode of its expression, he seems never to have reached the stage of moulding it into a completely deductive form.

The dynamics of the æther, in fact the recognition of the existence of an æther, has thus, as a matter of history, been reached through study of the dynamical phenomena of matter. When the dynamics of a material system is worked up to its purest and most general form, it becomes a formulation of the relations between the succession of the configurations and states of motion of the system, the assistance of an independent idea of force not being usually required. We can, however, only attain to such a compact statement when the system is self-contained, when its motion is not being dissipated by agencies of frictional type, and when its connections can be directly specified by purely geometrical relations between the coordinates, thus excluding such mechanisms as rolling contacts. The course of the system is then in all cases determined by some form or other of a single fundamental property, that any alteration in any small portion of its actual course must produce an increase in the total "action" of the motion. It is to be observed that in employing this law of minimum as regards the action expressed as an integral over the whole time of the motion, we no more introduce the future course as a determining influence on the present state of motion than we do in drawing a straight line from any point in any direction, although the length of the line is the minimum distance between its ends. In drawing the line piece by piece we have to make tentative excursions into the immediate future in order to adjust each element into straightness with the previous element; so in tracing the next stage of the motion of a material system we have similarly to secure that it is not given any such directions as would unduly increase the action. But whatever views may be held as to the ultimate significance of this principle of action, its importance, not only for mathematical analysis, but as a guide to physical exploration, remains fundamental. When the principles of the dynamics of material systems are refined down to their ultimate common basis, this principle of minimum is what remains. Hertz preferred to express its contents in the form of a principle of straightness of course or path. It will be recognised, on the lines already indicated, that this is another mode of statement of the same fundamental idea; and the general equivalence is worked out by Hertz on the basis of Hamilton's development of the principles of dynamics. The latter mode of statement may be adaptable so as to avoid the limitations which restrict the connections of the system, at the expense, however, of introducing new variables; if, indeed, it does not introduce gratuitous complexity for purposes of physics to attempt to do this. However these questions may stand, this principle of straightness or directness of path forms, wherever it applies, the most general and comprehensive formulation of purely dynamical action: it involves in itself the complete course of events. In so far as we are given the algebraic formula for the time integral which constitutes the action, expressed in terms of any suitable co-ordinates, we know implicitly the whole dynamical constitution and history of the system to which it applies. Two systems in which the action is expressed by the same formula are mathematically identical, are physically precisely correlated, so that they have all dynamical properties in common. When the structure of a dynamical system is largely concealed from view, the safest and most direct way towards an exploration of its essential relations and connections, and in fact towards answering the prior question as to whether it is a purely dynamical system at all, is through this order of ideas. The ultimate test that a system is a dynamical one is not that we shall be able to trace mechanical stresses throughout it, but that its relations can be in some way or other consolidated into accordance with this principle of minimum action. This definition of a dynamical system in terms of the simple principle of directness of path may conceivably be subject to objection as too wide; it is certainly not too narrow; and it is the conception which has naturally been evolved from two centuries of study of the dynamics of material bodies. Its very great generality may lead to the objection that we might completely formulate the future course of a system in its terms, without having obtained a working familiarity with its details, of the kind to which we have become accustomed in the analysis of simple material systems; but our choice is at present between this kind of formulation, which is a real and essential one, and an empirical description of the course of phenomena combined with explanations relating to more or less isolated groups. The list of great names, including Kelvin, Maxwell, Helmholtz, that have been associated with the employment of the principle for the elucidation of the relations of deep-seated dynamical phenomena, is a strong guarantee that we shall do well by making the most of this clue.

Are we then justified in treating the material molecule, so far as revealed by the spectroscope, as a dynamical system coming under this specification? Its intrinsic energy is certainly permanent and not subject to dissipation; otherwise the molecule would gradually fade out of existence. The extreme precision and regularity of detail in the spectrum shows that the vibrations which produce it are exactly synchronous, whatever be their amplitude, and in so far resemble the vibrations of small amplitude in material systems. As all indications point to the molecule being a system in a state of intrinsic motion, like a vortex ring, or a stellar system in astronomy, we must consider these radiating vibrations to take place around a steady state of motion which does not itself radiate, not around a state of rest. Now, not the least of the advantages possessed by the action principle, as a foundation for theoretical physics, is the fact that its statement can be adapted to systems involving in their constitution permanent steady motions of this kind, in such a way that only the variable motions superposed on them come into consideration. The possibilities as regards physical correlation of thus introducing permanent motional states as well as permanent structure into the constitution of our dynamical systems

* In 1870 Maxwell, while admiring the breadth of the theory of Weber, which is virtually based on atomic charges combined with action at a distance, still regarded it as irreconcilable with his own theory, and left to the future the question as to why "theories apparently so fundamentally opposed should have so large a field of truth common to both."—"Scientific Papers," II., p. 228.

have long been emphasised by Lord Kelvin ;* the effective adaptation of abstract dynamics to such systems was made independently by Kelvin and Routh about 1877 ; the more recent exposition of the theory by Helmholtz has directed general attention to what is undoubtedly the most significant extension of dynamical analysis which has taken place since the time of Lagrange.

Returning to the molecules, it is now verified that the action principle forms a valid foundation throughout electrodynamics and optics ; the introduction of the æther into the system has not affected its application. It is therefore a reasonable hypothesis that the principle forms an allowable foundation for the dynamical analysis of the radiant vibrations in the system formed by a single molecule and surrounding æther ; and the knowledge which is now accumulating, both of the orderly grouping of the lines of the spectrum and of the modifications impressed on these lines by a magnetic field or by the density of the matter immediately surrounding the vibrating molecule, can hardly fail to be fruitful for the dynamical analysis of its constitution. But let it be repeated that this analysis would be complete when a formula for the dynamical energy of the molecule is obtained, and would go no deeper. Starting from our definitely limited definition of the nature of a dynamical system, the problem is merely to correlate the observed relations of the periods of vibration in a molecule, when it has come into a steady state as regards constitution and is not under the influence of intimate encounter with other molecules. It may be recalled incidentally that the generalised Maxwell-Boltzmann principle of the equable distribution of the acquired store of kinetic energy of the molecule, among its various possible independent types of motion, is based irectly on the validity of the action principle for its dynamics. In the demonstrations usually offered the molecule is considered to have no permanent or constitutive energy of internal motion. It can, however, be shown, by use of the generalisation aforesaid of the action principle, that no discrepancy will arise on that account. Such intrinsic kinetic energy virtually adds on to the potential energy of the system ; and the remaining or acquired part of the kinetic energy of the molecule may be made the subject of the same train of reasoning as before.

(To be concluded.)

THE GENESIS OF THE IONS IN THE DISCHARGE OF ELECTRICITY THROUGH GASES.†

BY PROF. J. J. THOMSON, M.A., F.R.S.

In many cases of discharge through gases, the ions have not to be supplied by the action of the electric field itself, but are produced by external agents such as Röntgen rays, radiation from uranium and other radio-active substances, the action of ultra-violet light on metals, incandescent filaments, &c. In addition, however, to such cases as these we have the very important series of phenomena which includes the spark-discharge and the ordinary discharge through vacuum tubes in which there are no external sources available for the production of ions, so that these must in some way or another arise from the action of the field itself. There are many difficulties in the way of supposing that single molecules are torn asunder by the electric force in the field pulling the positive ion one way and the negative ion in the opposite way. To mention only one of these difficulties, the electric force necessary to produce discharge is almost vanishingly small compared with the force due to an atomic charge acting at an atomic distance. In my "Recent Researches" I suggested that under the action of the electric field some of the molecules formed long narrow aggregations, just as smoke and dust do under similar circumstances: these aggregations, being bodies of higher specific inductive capacity than their surroundings, will act on the lines of force like long and pointed conductors, and will therefore produce a great concentration of the lines of force on the ends of the aggregation, so that the maximum electric force in the field will be enormously greater than the average force, which is all we can measure. Since that was written, many investigations have been made which have proved that where electrified particles move through a gas ions are produced under certain circumstances, at any rate if the particle is negatively electrified. Thus Lenard showed that his rays make a gas through which they pass a conductor of electricity. Lenard rays are negatively electrified particles, and on our theory the conductivity of the gas is due to the production of ions. Again, I showed (*Phil. Mag.*, Oct., 1897) that the passage of cathode rays through a gas ionised it. Thus we have evidence that in some cases at any rate the motion of the corpuscles through a gas can ionise it. The view that the motion of the ions through a gas can ionise a gas is supported by the observation of Stoletow (*Journal de Physique*, IX. p. 468) that under the same electric force the current between two plates, one of which is illuminated by ultra-violet light, increases with the distance between the plates, the increase being most marked when the pressure is low. This is what we should expect if the negative ions, starting from the illuminated plate, produced in the passage through the gas fresh ions. The view which I wish to bring forward in this Paper is that the ionisation in the ordinary cases of discharge through gases is produced by the motion through the gas of ions or corpuscles already present in the gas. These ions or corpuscles under the action of the electric field acquire velocity and kinetic energy ; and when this velocity or energy reaches a definite value, which need not be the same for the positive as the negative ion, these ions or corpuscles are able, by their collision with the surrounding molecules, to produce other ions and corpuscles. This dissociation may be directly due to the collision, or indirectly to rays like Röntgen rays produced by the collision. Let us take the case of a gas through which a few ions are distributed: then, if the energy or velocity communicated by the electric field to these ions exceeds a certain critical value, each of the original ions will produce other ions, and these new ions will give rise to fresh ions, so that the number of ions and the conductivity of the gas will rapidly increase ; it will go on increasing until the conductivity of the gas reaches such a value that the strength of the electric field is reduced so that the work done by it on an ion is equal to the critical value ; when this stage is reached each ion produces one and only one successor, so that the number of ions remains constant, and the gas, with the discharge passing through it, attains a steady state.

If the strength of the field had been so small that the work done on an ion was not equal to the critical value, the number of ions would not increase, and there would be no discharge through the gas beyond the very slight leak due to the ions originally present in the gas. Thus this view explains why a field of finite strength is required to send the discharge through a gas.

The maximum kinetic energy given by the field to an ion will be measured by the work done on the ion during its free path, for after a collision the disturbance in the energy and direction of motion is so great that the work has, as it were, to be begun over again ; while if the direction of the motion is reversed, the field, if it increased the kinetic energy of the ion before the collision, will diminish it afterwards. Thus, if λ is the mean free path, the kinetic energy given by the field to the ion will be measured by $F\epsilon\lambda$, where ϵ is the charge on the ion and F the electric force. The condition that discharge should take place is that the maximum kinetic energy should equal q, where q is a quantity depending on the nature of the gas. Thus the condition for discharge is $F\epsilon\lambda = q$, so that F, the electric force required to produce discharge, varies inversely as the mean free path of the ions or corpuscles. Now λ is inversely proportional to the density of the gas, so that on this theory the electric force required to produce discharge should in the same gas be directly proportional to the density of the gas, a result which is approximately true over a wide range of pressures. Thus the theory we are describing gives a very simple explanation of the fact that it is easier to produce a discharge through a gas at a low pressure than through one at a high.

The theory readily explains why it requires a greater electric force to send a spark through a thin layer of gas than through a thicker one, provided the thickness of the thin layer is less than a certain value which is inversely proportional to the pressure. For in order that the ions should produce dissociation it is necessary that they should strike against the molecules of the gas, or if the dissociation is due to rays produced by the collision, that the layer should be thick enough to absorb the radiation ; but as soon as the thickness of the layer becomes comparable with the mean free path of an iron the chance of their striking against a molecule before reaching the electrode begins rapidly to diminish, so that the ability of the moving ions to produce dissociation will rapidly diminish when the thickness of the layer falls below a certain value. And although the thickness of the layer when the electric force begins to increase is large compared with the free path of a molecule moving through the gas, it is not so compared with the free path of a corpuscle ; *i.e.*, one of the small ions which are found in the cathode rays, and which we have reason to believe play an important part in all cases of electric discharge.

On this view of the electric discharge, the presence of a small number of ions is required to start the discharge. The experiments of Linss,* and the recent ones of Elster and Geitel†, seem to show that such ions are present in gases under ordinary conditions ; the first spark, too, is much more irregular in its behaviour than subsequent ones, and this is in accordance with the view that the conditions attending its formation are capricious and almost accidental.

Let us now consider the more complicated phenomena attending the passage of the discharge through a gas at low pressure. The production of ions may take place throughout the tube, or it may be localised in certain places. There must, however, be at least two places where ionisation takes place. For on this theory the ionisation at a place A is produced by ions brought into A by the electric field, so that there must be some other centre or centres of ionisation to produce the ions which are brought into A by the electric field. In the *Philosophical Magazine* for March, 1899, I showed how, from the study of the distribution of electric force in a discharge-tube, we could determine the places of maximum ionisation; the result of an investigation leads to the conclusion that there is one centre of ionisation close to the cathode, and another in the negative glow.

According to the view taken in this Paper these centres form mutually dependent and, as it were, regenerative systems, the ionisation in the negative glow being due to the corpuscles coming from the centre close to the cathode, while the ionisation close to the cathode is due to the positive ions which come from the centre in the negative glow. This view seems in accordance with the experiments of Villard,* in which a screen placed between the negative glow and the cathode stopped the emission of cathode rays from the portion of the cathode shielded by the screen. The negative corpuscles starting from the cathode ionise the gas in the neighbourhood of the magnetic glow, producing in this region a large number of ions; this makes the region one of great electrical conductivity, and the electric force consequently falls to a very small value. Let us now trace what would happen if there were no centre of ionisation between the negative glow and the anode; the current in this part of the tube would be carried by the negative ions produced in the negative glow, such a distribution of ions in the tube would cause the electric force to increase as we approach the anode, and, if this increase did not cause the kinetic energy of the ions to exceed the value at which they begin to produce other ions, the electric force would increase uninterruptedly up to the anode. If, however, the electric force increases to such an extent that the energy the field communicates to the ions is greater than that required for the dissociation of the surrounding molecules into other ions, then in the region where the electric force reaches this value fresh ions will be produced. This will increase the conductivity of the gas, and therefore cause the electric force to diminish; thus, after reaching a certain value, the electric force will fall off, and then begin to increase again after it has sunk below the value at which ionisation takes place. If this were repeated several times before the anode was reached, we should get the electric force waxing and waning, as it does in the striated discharge. The view that the striations consist of alternations of layers of high conductivity due to the ionisation of the gas by an electric force exceeding a certain critical value, with layers of gas through which the electric force is too low to produce ionisation, accounts for the distance between the striations diminishing as the density of the gas increases, and also for the distance between the striations in a tube of unequal bore being less in the narrow than in the broad parts of the tube. The electric force in the striated part of the discharge is much less than that close to the cathode; and it might be urged that if such an intense field were required to ionise the gas close to the cathode, the smaller field in the striated discharge would not produce ionisation. It must, however, be remembered that the ionisation at the cathode has to be produced by *positive* ions, while that in the rest of the field may be due to negative corpuscles; and it may very well be the case that the large positive ions are less efficient as ionisers than the negative corpuscles.

THE RUBBER INDUSTRY OF THE AMAZON VALLEY.*

Of late years the enormous consumption of rubber in the manufacture of bicycle tyres has created a very great demand. The supply not being able to cope with this demand the price has steadily increased, and considerable attention is now being paid to the production of rubber all over the world. So great is the demand at present that, although the supply from the Amazon Valley alone has increased from 8,635 tons in 1880 to 25,370 tons in 1899, the approximate price of 2s. 6d. per pound in 1889 increased to 4s. 6d. per pound in 1899. The British Vice-Consul at Manàos states that the total world's supply to-day is about 120,000,000lb. to 130,000,000lb., valued at about £15,000,000. At the present time laticiferous plants yielding "caoutchouc" or "rubber" are being worked for commercial purposes in Brazil, Bolivia, Central America, East and West Africa, whence come the chief supplies, while Guiana, the Eastern Archipelago, Madagascar, India, and Ceylon contribute a small quantity to the general stock. More than half the total supply is exported from the Amazon district. In Brazil several kinds of lactiiferous trees exist from which rubber is manufactured. In the State of Ceará, the *Manihot Glaziovii*, locally known as the maniçoba, is fairly extensively worked, and considerable attention is being paid to its cultivation. In the State of Maranhao the *Hancornia speciosa* or mangabeira is beginning to give results. These trees, however, are unimportant compared to the *Hevea Braziliensis* or seringueira, to which the Amazon Valley owes its present prosperity. The *Hevea Braziliensis* is found scattered through the forests that clothe the banks of the Amazon River and its tributaries. It does not strike the eye among the innumerable varieties of trees to be met with in the Amazonian forests, and is often difficult to detect. A peculiar glistening of the trifoliate leaves and the whiteness of the bark serves as a guide to the practised eye. The tree grows to the height of 70ft. to 100ft., and has, as a rule, when full grown, a girth of from 5ft. to 7ft. at a height of 1yd. from the ground. The tree flowers in January; the seeds are ripe and begin to fall in March in the case of old trees, and in May in the case of young trees. The seeds are contained in a hard shell, three or four in each shell, which hang by a short stalk from the upper and outer branches. When ripe the shell explodes, often with a loud report, scattering the seeds to a considerable distance. For this reason it is difficult to procure seeds. There are for practical purposes three distinct varieties of the "seringueira" to be met with in the forest. These are locally known as the seringueiras "casca vermelha" (red bark), "barriguda" (bellied), and "casca preta" (black bark). The first of these, the "casca vermelha," grows in the higher parts of the forest which are seldom or never flooded. The latex which it yields is scanty, thick, and will not run. Is is therefore of little value. The second of these, the "barriguda," so named because the trunk increases very rapidly in thickness towards the base, grows in those parts which are almost constantly flooded, named "igapós." It yields plentifully a thin, watery latex, which is of little value. The third variety, the "casca preta," grows in those parts where a certain amount of drainage exists, and which form an intermediary zone between the permanently flooded parts and the high lands. It is this variety which yields the latex from which the rubber of commerce is manufactured. The "latex," or as it is commonly known, the "milk" of the tree, is a milky juice contained in special tubes running amongst the other tissues of the plant. These tubes, in the case of the hevea, are connected, forming what is known as the "laticiferous system." The latex is quite different from what is called the "sap," and probably does not play any part in the nutrition of the tree. According to some authorities it forms a reserve of water to be drawn upon in cases of drought. The actual extraction of latex cannot kill the tree, and the common statement that the trees are "bled" to death is a mistake. As a matter of fact, though trees, exhausted, inasmuch as they will not yield any more latex are common—actually dead trees, killed by overtapping, are rarely met with. The latex as it exudes from the bark is of a dazzling whiteness, resembling milk, which it also resembles in composition, inasmuch as it consists of an emulsion in which "caoutchouc" takes the place of the butter in the ordinary milk. The fluid part of the latex consists of water with very small quantities of albuminous matter, organic acids and phosphates in solution. The extraction of the latex, or as it is usually called the "tapping" of the tree is effected by making an incision in the bark of the tree. From this incision the latex flows for about three or four hours, after that it stops flowing of its own accord. The incision should not penetrate beyond the bark, which is generally about ⅛in. thick, into the wood of the tree, and for this reason a very small axe, which rapidly thickens wedge like from the cutting edge is used, the shape of the instrument preventing its entering too deep. The axe is generally about ¾in. wide. The custom is to strike with it a backhanded blow upwards, thus making an oblique cut in the bark. It is probable that a better method would be to use a chisel and mallet and make a V-shaped incision. Recent experiments at Henaratgoda have shown the advantage of this shaped incision. The incision having been made, a small tin cup, of a capacity of about 4oz., is affixed just below it to receive the latex as it flows. This is effected by pressing the edge of the cup—which is sharp—into the bark, until it gets a sufficient hold to remain firm. By this method, however, a second wound is made in the bark, which is injurious. No better method has yet been suggested. In some places a winding groove is cut in the bark of the tree, and by means of a clay breastwork the milk is conducted into a vessel placed at the foot to receive it. This method is found, however, to be very exhausting to the tree, and is falling into disuse. The usual mode of tapping is to make an incision with the axe at the height of some 6ft. or 7ft. from the ground; on a level with that incision and at a distance of some 8in. a second cut is made, and so on round the tree. On the next day incisions are made just below these, and so on day by day, until they reach the ground. Incisions are then made on the same plan, beginning, as before, from the top, and working downwards between the former rows. A tree that will carry seven cups 8in. apart is

* From the *Journal* of the Society of Arts.

Digitized by Google

considered a large one, and although trees that will carry eight or nine cups are to be met with, the average do not carry more than four or five. The latex having been obtained and collected, the caoutchouc, or rubber known to commerce, may be obtained from it in various ways. The only method, however, that has met with practical success is that of evaporation, by which the watery portion of the latex is driven off, and solid caoutchouc remains. The object to be secured is that as little water as possible shall remain in the caoutchouc, the putrefaction of the caoutchouc owing to the presence of these matters being extremely detrimental to its elastic properties, and therefore to its market value. In the Amazon district the method followed is to light a fire upon the ground, and to invert over it a specially-constructed, funnel-shaped chimney. From the narrow end of this funnel, which is open, the smoke and heated gases pour out in concentrated form. The fuel used for the fire consists, as a rule, of chips from any hardwood tree that grows handy to the labourer's hut. The nuts of the "Urucury palm" (*Attalea excelsa*) are sometimes used, their smoke containing a trace of acetic acid, and creosote being found particularly effective in curing the rubber and preventing putrefaction. It is, however, a mistake to suppose that all or even a large proportion of the rubber coming from the Amazon district is cured in this way. It is, on the contrary, very rarely that the rubber cutter will be at the trouble to collect these nuts, he nearly always prefers to use wood chips, which give him less trouble to procure. The fire having been made, and a large stream of hot smoke pouring out of the chimney, the operator seats himself on a small stool by the side of it. The latex is contained in a basin placed at hand. In his right hand he holds a paddle-shaped piece of wood, in his left hand a small calabash. Dipping the calabash into the basin of latex he pours a small quantity over the paddle, which he then revolves in the smoke issuing from the chimney. That having dried in a layer over the paddle he repeats the operation. In the course of time a "ball" or "biscuit" of solid rubber is thus formed. In some parts where it is the custom to manufacture very large balls or pellets, an arrangement is made by means of a pivot to rotate the ball over the chimney. The wooden core is withdrawn through a slit made in the "biscuit," or simply drawn out in the case of the pellet. The latex of a tree named "macaranduba" (*Mimusops elata*), and more often that of a tree named locally "amapa" is sometimes used to adulterate that of the *hevea*. In both cases the adulteration is extremely prejudicial to the quality of the rubber produced. Three distinct qualities of rubber are manufactured in the Amazon district, namely, "fine," "entrefine" and "sernamby" respectively. "Fine" rubber has been well smoked, and is free from putrefaction. "Entrefine" rubber has been either burnt while being smoked, or has been insufficiently smoked, and has, therefore, putrified. It is due to carelessness on the part of workmen, which it should be possible to avoid. "Sernamby" is the "negro-head" of commerce, and consists of scraps mixed with dirt, or strips peeled off the bark of the tree and mixed with impurities of all sorts.

* Villard, *Journal de Physique*, January, 1900.

ELECTRICITY WORKS ACCOUNTS.

The Bournemouth and Poole Electricity Supply Co. (Ltd.).

Under this new title the Bournemouth Company present their accounts for 1899, the undertaking of the Bournemouth and District Electric Supply Co. having been vested in the new company.

Owing partly to directors' fees, which apparently were not incurred during the period, and to other unusual charges appearing in the accounts, the management costs show somewhat of an increase on those of 1898, and now stand at a figure distinctly above the average under similar conditions. On the other hand all the items of generating costs, although they also show a slight increase, are under the average, and present excellent figures.

The resulting works costs at 1·96d. per unit are quite a farthing under what they might have been expected to stand at.

The increases in the output and lamp connections indicate healthy progress; the former advanced 27·4 per cent., and the latter by 30·7 per cent. on the 1898 figures.

We are glad to see that the low load factor of only 8·16 per cent. in 1898 has improved to 8 49 per cent. In view of the company's intention to supply power to the tramways connecting Bournemouth and Poole, it is not too much to expect that the character of the load will be still further improved to the great advantage of the undertaking.

Hastings and St. Leonards Municipal Electric Supply Works.

Although our analysis of the accounts of this undertaking for 1899 shows that, as compared with 1898, a decided improvement in the various items of works costs has been effected, yet we must say that the results are disappointing.

In a comparison of the generating costs with those at other stations the fuel item is at a disadvantage owing to the existence of heavy town dues on coal. In the fuel item in our table these dues amount to £279, being a charge of 2s. 4d. per ton of coal.

The Corporation electrical engineer having been unsuccessful in inducing the committee to waive this charge, as being only a matter of accounts between departments, recommended, as we understand, that the public lighting department be surcharged to meet the dues, thus relieving the price to private consumers. As he points out, under this arrangement the fuel item and the public lighting charges appear high in comparison with other towns.

Unfortunately, after making due allowance for this charge the fuel item and, indeed, all the generating, as well as the management and property charges are still to such an extent above the average as to result in a total costs figure quite 1·5d. above what it should stand at under similar conditions of output and load factor.

As compared with 1898 the output shows but the small advance of 11·8 per cent. The additional lamp connections indicate, however, much better progress, having advanced the total by 31·1 per cent.

The following table gives an idea of the progress of the undertaking. Last year was the first under municipal administration:—

Year.	Output units sold.	Equiv. lamp c'nnections.	Load factor.	Rev. per unit sold.	Total costs per unit sold.	Working profit.	Dividend (under c'mp'ny).
1895	265,846	9,667	...	5·76d.	4·64d.	£1,246	nil
1896	283,100	10,064	12·6%	5·92d.	4·37d.	1,894	nil
1897	338,705	13,418	12·5%	6·30d.	3·86d.	3,426	6%
1898	363,678	14,817	12·7%	6·76d.	4·58d.	3,302	7¼%
1899	404,866	19,423	12·8%	6·94d.	3·95d.	5,046	...

The following is a list of electric supply works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared:—

Aberdeen (Municipal)	Jan. 12, 1900	Kingston-on-Thames (Mun.)	July 20, 1900
Ayr (Municipal)	Sept. 22, 1899	Lancaster (Municipal)	Jan. 19, ,,
Bath (Municipal)	April 20, 1900	Leeds (Municipal)	Dec. 1, 1899
Bedford (Municipal)	Aug. 3, ,,	Leicester (Municipal)	Jan. 26, 1900
Belfast (Municipal)	July 6, ,,	Leyton (Municipal)	Sept. 8, 1899
Birmingham (Company)	Sept. 15, 1899	Liverpool (Municipal)	June 23, 1900
Blackburn (Municipal)	Jan. 19, 1900	London (Company)	June 8, ,,
Blackpool (Municipal)	Sept. 29, 1899	Londonderry (Municipal)	Feb. 16, ,,
Bournemouth (Company)	April 28, ,,	Manchester (Municipal)	Aug. 11, 1899
Bolton (Municipal)	Nov. 24, ,,	Newcastle and District (Co.)	Oct. 6, ,,
Bradford (Municipal)	June 22, 1900	Newcastle-upon-Tyne (Co.)	April 14, ,,
Brighton (Municipal)	May 4, ,,	Newport (Mon.)(Municipal)	Dec. 15, ,,
Bristol (Municipal)	Aug. 24, ,,	Northampton (Company)	Oct. 20, ,,
Bromley (Kent) (Co.)	June 15, ,,	Norwich (Company)	Nov. 17, ,,
Brompton & Kensington (Co.)	Mar. 23, ,,	Notting Hill (Company)	Mar. 16, 1900
Burnley (Municipal)	Aug. 25, 1899	Nottingham (Municipal)	July 21, 1899
Burton-upon-Trent (Mun.)	April 21, ,,	Oldham (Municipal)	Dec. 1, ,,
Bury (Municipal)	Sept. 22, ,,	Oxford (Company)	April 13, 1900
Cambridge (Company)	April 13, 1900	Pontypool (Company)	May 5, 1899
Cardiff (Municipal)	Dec. 15, 1899	Portsmouth (Municipal)	Aug. 24, 1900
Charing Cross (Municipal)	Mar. 9, 1900	Prescot (Company)	Dec. 8, 1899
Chelsea (London) (Co.)	Mar. 23, ,,	Preston (Company)	Sept. 29, ,,
Cheltenham (Municipal)	Nov. 10, 1899	Reading (Company)	Oct. 13, ,,
Chester (Municipal)	Aug. 3, 1900	Richmond (Company)	June 29, 1900
City of London (Company)	June 15, ,,	Salford (Municipal)	Feb. 23, ,,

BOURNEMOUTH.—REMARKS—*a* Over-expended. *b* Includes directors' remuneration £200. *c* Includes £95 to insurance, £80 to "Stores and works expenses," and £37 to auditing. *d* On Wright system (1½-hour scale). *e* On Wright system (1-hour scale). *f* Includes £3,885 on transformer sub-stations. *g* Includes £22,601 (expended during 1899) "Special items." *h* Includes £78 "Stores and works expenses." *i* Inclusive of £47 to auditing and £101 to insurance. *j* Inclusive of £800 directors' remuneration for two years.

HASTINGS AND ST. LEONARDS.—REMARKS—* Inclusive of 830 as the assumed equivalent in 8 c.p. lamps of the 53 arc lamps. *a* The total purchase price of the undertaking, including £3,200 paid for the "Front" lighting installation, was £61,200. *b* Over-expended. *c* Includes £1,743 in respect of current consumed and £733 actual cost of repairs and attendance to lamps, and interest and sinking fund on capital expended on public lighting plant. *d* Includes £38 to auditing and £134 to insurance. *e* This profit, sufficient for a dividend of 7½ per cent. on the ordinary share capital of £27,220, was disposed of by being added to the profit on the sale of the undertaking, thus realising to the ordinary shareholders of the late Company a total dividend of £2. 3s. per £10 share. *f* Plus a charge of 1s. per quarter per 8 c.p. lamp. *g* Or 6d. per unit, and 5s. meter rent per quarter. *h* Includes £54,800 consideration money for purchase of undertaking under contract of July 23, 1897, and £6,548, amount paid to the company in respect of new and improved machinery and plant, alterations to buildings, extension of mains, transformers, &c., carried out by company subsequent to date of above contract. *i* Includes £279 coal dues. *j* Inclusive of £185 to insurance and £274 expenses of executing the order. *k* Per cent to capital at end of year (£78,916).

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny
Editorial Publishing and Printing Offices,

2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to THE EDITOR.

All letters for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	

New Volumes of "THE ELECTRICIAN" *commence in April and October.*

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of THE ELECTRICIAN" *Printing and Publishing Company, Limited. The well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. ELTON YOUNG, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. FISHER and J. C. H. DARBY. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. PHILLIPS. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints" on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. FISHER. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. RAPHAEL. Price 5s., post free.

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. Vol. II. Price 12s. 6d.; post free, 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. New Edition. 93 original illustrations, price 6s.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. New edition. Price 10s. 6d., post free; abroad 11s.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d. post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free 2s. 2d. each; strong cloth 2s. 6d., post free 2s. 9d. each. Single Primers 2d., post free 2½d.

WIRELESS TELEGRAPHY: SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES. By Dr. O. J. LODGE. New Edition. Price 5s. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, ELECTRIC TRACTION, TELEGRAPHS, TELEPHONES, &c. A. C. CURTIS-HAYWARD, B.A. To January, 1900. Price 3s. 6d., post free.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By FRANCIS JEHL. Price 10s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

THE ELECTRIC ARC.—By Mrs. AYRTON. This work is in the press and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. WADE. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. RAPHAEL. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

THE TELEPHONE.—By DANE SINCLAIR and F. C. RAPHAEL.

SPECIAL NOTICES.

NOW READY.—Vol. XLIV. of "THE ELECTRICIAN" (950 pages) bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of "THE ELECTRICIAN" (1878-1900) can now be supplied. These sets are very scarce, and early application should be made

AN INDUSTRIAL OBJECT LESSON.

The introduction of electric power supply on an extensive scale and at a cheap rate is a change in the conditions of material civilisation which cannot fail to exert a deep and widespread influence on industrial and social life. Electrical engineers, political economists and even leading statesmen, such as Lord SALISBURY, have studied this subject in its various aspects. One aspect of the subject, viz., its relation to land development, was considered in our leading article last week. There has recently been placed before us a number of particulars relating to an example of industrial power supply that constitute an instructive object lesson, from which it appears feasible to derive a number of useful inferences. Our readers will remember that a short time ago electric power supply works, deriving water power from the river Isar, were started at the then insignificant village of Höllriegelsgerent, a few miles above Münich. The works were driven by four turbines and had an aggregate rating of 2,000 H.P., exclusive of some 1,000 H.P. in reserve steam plant. It was the object of the promoters of these works to supply electric power over an extensive rural area for agricultural and other industrial purposes. So successfully were the requirements of the neighbourhood divined and its industrial possibilities perceived, that already no less than 25 farms and in all 90 premises of various kinds are supplied with light and power, the area covered including as many as 21 villages and rural districts near Münich. The load is composed of 151 motors—to which 21 new motors are being added—besides 13,500 glow lamps and 329 arc lamps. Mains for the supply to these items aggregate 56 miles of feeders and 30 miles of secondary distributors. It is none too early therefore that the decision has been made to provide additional 4,000 H.P. at the power station.

But it is not merely to call attention to the rapid success of these works that we have cited them. An entirely new industrial district has been created before now by the establishment of cheap electric power supply: there is nothing novel, however satisfactory, in that; numberless instances might be mentioned, were the entire civilised world to be scanned, though, by-the-way, not an instance of this type occurs in this country. But the most striking feature in the experiment on the Isar is the creation of a vigorous competition between the electrical area

Digitized by Google

and the town of Münich, in regard to the location of factory sites; for not only have new works sprung up within the electrical area, but established works in Münich have been abandoned, their industries being transferred from town to country. The official report from H.M. Legation at Münich, from which we derive the facts about this interesting experiment, states that "many of these works previously sold their valuable buildings and sites in the centre of the town, bought far cheaper sites with siding connections with the railway, and built workmen's dwellings adjoining at great profit and economy in working expenses."

Now we will grant that at first glance these results appear to justify the view which is sometimes advanced—and it is a view that has captured the popular fancy—that cheap and abundant electric power supply has a tendency to decentralise industrial life, breaking up the closely-populated manufacturing city and scattering its factories in a deliciously healthy uniformity over an unsmirched country. In the same manner, this experiment might at first sight be supposed to show how electric power supply develops the value of land—not heeding, for the moment, any depreciation in value of the forsaken factories in Münich. But we think that on closer inspection neither of these inferences will be found to be justified. In the first place, it is important to bear in mind that the electric power is merely an intermediary agent; the real source of power is in the river Isar, at a particular spot. Prior to the commencement of electric supply this power could not attract industry on any extensive scale, because factories would be unable to crowd sufficiently close to the water power. Electric power has enabled many more factories to crowd round the water power by giving this latter a larger and more practicable radius of action; but the tendency is still to crowd round. There is no inducement to select a site as remote from the river as electric power can be conveyed; but, on the contrary, to get as near to the power-house as rents and other considerations will allow, because in that case electric power will be the more cheaply obtained. It will be seen then that this type of electric power scheme is just as centralising in its tendency as is steam power; perhaps even more so, since coal can be distributed without additional net cost over so much larger an area. Bearing in mind also that the real explanation of the industrial phenomena exhibited in this experiment is the existence of a large source of water power, it will be seen that there can be no parallel between this experiment and the large electric power schemes promoted in the United Kingdom, in regard to the appreciation in land and property values. As, however, we have already dealt with this matter so recently, we shall not proceed further with it now.

While dealing with the effect of electric power in reforming town and city life, we cannot fail to notice an important influence, quite apart from the effect on the so-called factory system. Although, as we have said, we fail to discover that electric power supply tends to break up the individual factory into a number of home-workshops, or to scatter factories broadcast throughout rural districts, there is no difficulty in perceiving one direction at any rate in which electricity is doing much towards the amelioration of city life. We refer to electric traction—the influence of cheap and rapid transit, on electric tramways and suburban railways, in providing ready means for the city toiler to have his home in the neighbouring country. Some time ago we directed the attention of the authorities responsible for a satisfactory solution of the problem of "the housing of the poor," to this very effective and practicable solution. We have been glad to observe from time to time that local authorities throughout the country have been strongly disposed to accept this solution, which we have frequently pressed upon their attention, and that the great social value of electric tramways is being more and more recognised by them.

THE USE OF ALUMINIUM FOR ELECTRICAL CONDUCTORS.

BY JOHN B. C. KERSHAW, F.I.C.

(*Concluded from page 671.*)

PART II.—PRACTICAL APPLICATIONS.

Electric Power Transmission.—Details of the more important power transmission schemes in which aluminium has been used, or is about to be used for the overhead work, are given below in tabular form:—

Aluminium Transmission Lines in America.

Name of company.	Locality supplied.	Power transmitted.	Length of line in miles.	Voltage used.
Snoqualmie Falls Power Co.	Tacoma-Seattle	10,000	34	29,000
Blue Lakes Power Co.	Stockton	1,000	46	25,000
North Yuba Power Co.	Sacramento ...	1,000	63	?
Hartford Electric Light Co.	Hartford	2,000	11	10,000
Municipal Supply Co., Orillia, Ontario	Ragged Rapids and Orillia	2,000	13	?
Big Cottonwood Power Co.	Utah	500	?	12,000
Telluride Power Co.	Provo, Utah...	2,000	80	?
Standard Electric Co.....	San Francisco	?	150	60,000
Niagara Falls Hydraulic Power Co.	Niagara Falls	3,000 1,000	1½th	?

One or two of the above schemes are not yet completed, but all are expected to be in operation before the close of the present year.

The following are additional details concerning some of the lines:—

Niagara Falls Lines.—Both these lines are short, and convey current from the generating station to works in the neighbourhood only. According to Dunlap the cable supplying current to the National Electrolytic Co.'s factory for chlorate production, consists of 12 separate cables of No. 10 wire, and where it runs down the Penstock, bars of aluminium 6in. wide by ¼in. thick have been used. The metal from which the wire was drawn tested 99·5 per cent. aluminium. Molten tin was used to make all the joints on both bars and cable.*

The second aluminium conductor conveys current to the No. 2 works of the Pittsburg Reduction Co., but no details concerning this conductor have come under the writer's notice. Both conductors are stated to be working satisfactorily.

Snoqualmie Falls (Washington) Line.—In connection with this power scheme, 150,000lbs. aluminium have been used, but the full 12,000 H.P. has not yet been transmitted. The line runs between Tacoma and Seattle, and is constructed of wire drawn from an alloy containing 1½ per cent. copper. Spans of 120ft. are safely used with this wire. The Seattle branch of this line has now been in operation over twelve months, and in February of this year it was stated to be working satisfactorily.† The line is constructed of No. 1 and 2 B. and S. gauge wire. The MacIntyre mechanical joint is used, the sleeves being 9in. long by $\frac{1}{16}$in. thick. The Seattle line has required 67,000lbs. aluminium and the Tacoma line 72,000lbs. Triple petticoat porcelain insulators, 4¼in. high by 6½in. diameter, are used, each of which weighs 4lbs. The average span on the Seattle line is 110ft. and on the Tacoma line 150ft.‡

Blue Lakes and Stockton Line.—Three-phase current was used on this line, and it was operated for 10 months with success, but in January, 1900, the power-house was destroyed

* *Western Electrician*, July 30, 1898.
† *Aluminium World*, February, 1900.
‡ *Electrical Review* (New York), September, 1899.

Digitized by Google

by fire, and the opportunity was seized to replace the whole line by a heavier wire. The new line is not yet carrying current. The former line possessed a conductivity of 59·9—(copper 100). The tensile strength was 14·6 tons per square inch, and spans of 120ft. were used. 1,000,000lbs. of aluminium are to be used in constructing the new line. At 29 cents. per pound, this represents an outlay of £60,400 for the metal alone. Very full details regarding this line will be found in a Paper read by Messrs. Perrine and Baum before the American Institute of Electrical Engineers in May, 1900, and reprinted in full in the journal named below.*

Tariffville and Hartford Line.—The three-phase system of transmission is used on this line. The cable consists of seven strands, each strand made up of seven No. 11 B. and S. gauge wires. The diameter of the cable is $\frac{3}{4}$in., and it weighs about 1,500lbs. per mile. 20,160lb. of aluminium has been used for the scheme.†

Telluride Power Co.'s Line, Utah.—The line used to distribute electric power over this 80-mile circuit and to supply the mines at Mercur and Tintic is of $\frac{3}{8}$in. wire. The amount of power transmitted is to be increased as soon as the requisite machinery can be installed.

Sierra Nevada and San Francisco Line.—The scheme of the Standard Electric Co. of San Francisco for transmitting electric power from the foot of the Sierra Nevada Mountains to the city of 'Frisco, a distance of 150 miles, at 60,000 volts pressure, is likely to be fully completed in the course of the next few months. Aluminium cables, each consisting of 37 strands, are to be used for the overhead line, and the main trunk line will be 150 miles in length. The total capital outlay upon the scheme is estimated at £415,000.

Electric Tramways and Light Railways Transmission.—Although the use of aluminium in connection with traction developments is not proceeding so rapidly as in connection with industrial and mining undertakings, there are nevertheless instances in which it is receiving trial on an extensive scale for tramway or railway work. Thus the North-Western Elevated Railway Co. of Chicago have used 150,000lbs. aluminium to equip their overhead track in Chicago, and the line was started with the new power in the spring of this year. Very full details of the size of cable used and of the method of laying it alongside the track have been published in the American papers,‡ and some notes upon this cable have already appeared in the issue of *The Electrician* for June 2, 1899. Each cable contains 47 strands aluminium wire, grouped in sevens, and measures 1½in. in diameter. Vitrified clay blocks are used to insulate the cable, which is laid in wooden troughs. The inter-urban electric railway between Kansas City and Leavenworth has also been equipped with aluminium, and 70 miles of cable is stated to have been used for this line. The cable is $\frac{3}{4}$in. diameter, but no other details concerning it have been published. The Manhattan Elevated Railroad Co. of New York have also decided to use aluminium as conducting material on their line, and the transformation from steam to electric traction is now in progress. It is also reported that aluminium is being used experimentally upon a trolley line of electric tramways in this country, but the writer has been unable to obtain any details concerning these trials of the new metal for electric tramway work. Whether the skin of oxide which forms on all aluminium surfaces will render the metal unsuited for traction purposes, as suggested in *The Electrician* note of September 8, 1899, remains to be seen. Evidently in the States they do not consider this objection to aluminium of any importance.

Electric Light Cables.—Since aluminium cables for equal conductive capacity possess 1·68 times the sectional area of copper, it is evident that when insulated cables are necessary the latter metal has a decided advantage. On this account aluminium has never been used as a conductor excepting for overhead work, and for one or two of the schemes in which bare cables are laid along the surface of the ground, as for example, in electric railroad work.

As distributing systems for lighting purposes are practically always underground, insulated cables are used, and the writer has only record of two instances in which aluminium has been used for electric lighting schemes. One of these is in this country at Northallerton, where a small electricity supply company has made use of 4 miles of the light metal. Three sizes of wire were used, namely, 0·662in., 0·465in., and 0·380in., and screwed sockets were used for jointing purposes.* The writer has been in direct communication with this company with regard to their experiences with aluminium for distributing purposes, but so far the information promised has not come to hand.

The other instance in which the new metal has been used on a lighting system is in the United States of America, the Waxahachie Electric Light Co. of Texas having made use of aluminium in their distributing network about the year 1898. Their use of aluminium has, however, been restricted to short sections of their line, and only 2,700lbs. has yet been used.

The British Aluminium Co. informed the writer last November that aluminium had been supplied by the Foyers Company to various places in the North of England during 1899 for conducting purposes—in one case 1½ tons being supplied—but it was not stated whether the wire and cable supplied were to be used for traction or lighting systems.

Telegraph and Telephone Lines.—The use of aluminium for telegraphic and telephonic lines is making some progress. The Pennsylvania Railroad Co. is stated to have 16 miles of aluminium line in operation, wire of 0·144in. diameter being used.† The new telegraph line between Manilla and Cavite in the Philippines, 40 km. in length, is also of the new metal, and a wire 0·130in. in diameter has been employed. The Pacific States Telegraph and Telephone Co. are stated to have 200 miles of aluminium wire in use. Annoying breaks occurred at first, but these are now attributed to bad lots of wire having been used in the first installation.§

As regards the use of aluminium for similar work in this country and its dependencies, Sir William Preece has stated that it is now on trial in certain districts for long distance telephonic communication, and that he has recommended its use for telegraphic purposes in Africa.‖ The only unsatisfactory reports concerning this use of aluminium come from Messrs. Perrine and Baum, who state that in Washington and Oregon the telephone companies have experienced so much trouble with breaks in their aluminium wires, that they are replacing them.¶

On the other hand H. D. Fitch, a manager of the New York Telephone Exchange, has stated that in New York the new metal has answered well for telephonic communications, and that spans of 450ft. and 600ft. had survived two winter's exposure without mishap.** In view of this conflicting testimony, one can only conclude that the early breaks in aluminium overhead wires were due to defects either in the original wire, or to careless erection, and insufficient allowance for its high coefficient of expansion.

Conclusions.—The facts given above prove that aluminium has already made considerable progress as a substitute for other metals in overhead line construction for both telegraphic and power purposes. It has been stated that 500 tons of aluminium were used for these purposes alone in the United States of America in 1899. Whether this progress will continue, however, depends largely upon the further experience gained with the installations already in operation.

Prof. Forbes, in his Paper upon "Power Transmission," read before the Electrical Engineers in London on April 26th of this year, stated that the Westinghouse Company of the United States of America, which had recommended the light metal for use on the Tacoma and Seattle line, when asked to specify for its use on the proposed power transmission scheme in

Mysore, India, had replied that its use was "too experimental" to permit of this.

For an American firm to make such an admission after trial of the new material for conductors is startling, and proves that even in that land of progress mistakes are sometimes acknowledged. That there is need for further investigation of the whole subject is certainly proved by this decision of the Westinghouse Company *not to advise* the use of aluminium for the Mysore scheme. The latest reports of Messrs. Perrine and Baum concerning the Californian transmission lines are also not reassuring, although these investigators consider that the breaks are due to causes which may be avoided or overcome, and as the following extracts show, they are willing to pin their faith to the future of aluminium as a conducting medium:—

In all of these cases it seemed almost impossible in certain sections to keep the wire on the poles, and in these portions the lines have been finally taken down and replaced by other wire of either copper or aluminium. The writers have examined many breaks from these lines, and would judge from the appearance of the fracture that the cause, whatever it may be, was similar. In those breaks there are many small flaws, but by far the greatest majority are clear, sharp fractures, with but a slight reduction of area, and that entirely on one side—a break very characteristic of improperly mixed and brittle alloys. Partially from the appearance of the fracture, and partially from the fact that the breaks appear only in certain sections of the line, the writers are of opinion that this trouble is due to the presence of impurities in the material. This view is strengthened by the fact that when measurements were made on the line of the Yuba Power Company, the resistance of the whole line was found to be 10 per cent. greater than it should have been if it were made of the quality of material described in the earlier part of this Paper.

As a general conclusion, it is the opinion of the writers that aluminium can be safely used in place of copper where the proper precautions are taken in inspecting the wire before it is erected, and in erecting it with due consideration of its peculiar properties—of low and indefinite elastic limit, high coefficient of temperature expansion, and active electrolytic power.

Messrs. Perrine and Baum have therefore advised the erection of a new aluminium transmission line in connection with the Blue Lake and Stockton scheme, of somewhat heavier wire than the line which was first erected. But the writer feels some doubt as to the correctness of Messrs. Perrine and Baum's assumption that difficulties arising from impurities and lack of physical strength are the only ones that have to be surmounted in the successful use of aluminium for overhead transmission lines. The resistance of the metal to atmospheric influences is by no means so great as was at one time imagined, and the proof is still lacking that an aluminium transmission line will possess the permanent efficiency of one constructed of the rival, but dearer, metal—copper.

The writer last year discussed the liability of aluminium to corrosion, on exposure to damp impure atmospheres, very fully in the Paper named below*, and gave a summary of recent communications on the subject presented by Moissan and Ditte to the French Academie des Sciences. The need for experimental work upon the resisting power of aluminium to atmospheric corrosion before using the metal for large power schemes was insisted on, and the recent experiences in the Western States only further emphasises the need for such independent investigation.

In the Paper before the Electrical Engineers already referred to, Prof. Forbes stated that he was carrying out some exposure tests with several hundred feet of aluminium wire in Scotland; and the writer for the past 10 months has also had a large number of samples of wire of various metals and alloys exposed in two different localities in South Lancashire, under conditions somewhat similar to those obtaining in overhead transmission lines.

The results of these independent observations and of the further experience with the power transmission lines erected in America and elsewhere will be of considerable interest, for if aluminium does not possess the requisite resisting power to atmospheric corrosion, its use as a conducting material will be greatly hindered, and the caution displayed by English engineers in regard to its use for electrical conductors will be fully justified. If, on the other hand, aluminium is found to have all the physical characteristics demanded for overhead construction in schemes of electrical transmission, the future of the metal as an electrical conductor will simply depend upon the relative costs of aluminium and copper, and until the price of copper falls below £60 per ton the lighter and cheaper metal is certain to find increasing support from electrical engineers, especially on the other side of the Atlantic, where the atmospheric conditions are more favourable than in Western Europe.

Prof. Forbes has not stated whether he intends to publish the results of his own observations. The writer has nearly completed the first series of those in which he is engaged, and he hopes to publish the figures obtained before the close of the present year.

* *Lightning*, July 13 and August 17, 1899.

WHAT TO DO WITH OUR BOYS.

This is a question that is constantly giving parents and guardians concern, as it has done for a good many years past. The development of the electrical industries has undoubtedly assisted in answering the question, not only in regard to boys, but in a great measure also in regard to girls. The telegraph and telephone services have found, and will continue to find for some years to come, employment for a large proportion of our surplus female labour, and it would appear that the developments of telegraphy, both submarine and ærial, opens the door for a much larger force of operators than is at present being attracted to the service. We have on several occasions dealt with the educational requirements of the budding electrical engineer, and now a communication we have received from Messrs. Preece and Cardew, on behalf of the Cape telegraph authorities, points to the opportunities which the telegraph service in Africa offers to fairly educated young men.

We may take as an example the classification of the Cape Colony posts and telegraphs. Lads enter this service in the 5th Class (probationers) with a commencing salary of £60 per annum. When competent to take charge of a public wire, or to perform duties of like importance on the postal side, they receive an increase to £75 per annum, rising by £15 annually to £105 per annum. On promotion to the 4th Class the commencing salary is £120 per annum, rising by £12. 10s. annually to £145; in the 3rd Class the commencing salary is £160 per annum, rising by £12. 10s. annually to £197. 10s.; in the 2nd Class the commencing salary is £210 per annum, rising by £12. 10s. annually to £247. 10s.; and in the 1st Class the commencing salary is £260 per annum, rising by £15 annually to £320.

It will be seen that the Cape telegraph service compares favourably with the openings offered at home for young men. The department under Mr. French at Capetown has a training college, and doubtless eligible lads from the mother country would be welcomed, as it would appear from present requirements that the supply of operators in South Africa does not anything like keep pace with the demand, and we believe the same remark applies to the telegraph service generally, at home, and the Colonies, and abroad.

We announce on another page that the immediate requirements at the Cape is for sounder clerks, who must be from 19 to 25 years of age, single, and competent to send clearly about 30 words per minute. For such candidates as can show, at 19, four years' certified manipulative experience the commencing salary is £132. 10s. per annum; five years' experience at 20, £145 per annum. In the latter case promotion to the next class, with the minimum pay of £160 may follow after a three months' trial if the candidate is then able to satisfactorily take his full turn at any of the main lines.

Candidates with under three years' experience who possess the necessary minimum skill (30 words per minute) may still be taken on at £120.

Second-class passage is paid contingent on the signing of a two years' agreement. The salary is payable from the date of embarkation. The appointments are not by transfer from the English Post Office as in former years.

When it is further remembered that the railway system throughout Africa is greatly extending, and that the opening up of our newly-conquered territories and beyond is one of the first questions to be considered when peace is restored, it follows that the railway telegraph service alone must afford skilled and well-paid employment to large numbers of young

Digitized by Google

men. We are, therefore, quite apart from present needs, fully justified in calling the attention of parents and guardians to the telegraph and telephone services as those which will go far to solve the problem "What to do with our Boys."

We have not, in these brief remarks on an interesting subject, dealt with the question of supplementing the present training facilities for the two services; but clearly these facilities are not adequate, and it is for the Governments of the world, into whose hands the telegraph and telephone systems are drifting, to do more than is now done to satisfy the educational needs of a great profession. The training afforded in the schools of the Postal Telegraph service is for its own requirements solely; private enterprise, aided in a small measure by a few polytechnics and other scholastic institutions, are alone the sources from which the Colonies can draw. It is obvious that these will not suffice to meet the requirements for skilled operators which is already a feature of the almost universal demand for more telegraphs and more telephones.

A PRACTICAL TELEGRAPH TRANSMITTER USING THE SINE-WAVE FOR OPERATING THE WHEATSTONE RECEIVER.*

BY ALBERT C. CREHORE AND GEORGE O. SQUIER.

The Paper pointed out that the existing Wheatstone transmitter consists of an apparatus driven by clockwork, through which a band of perforated paper is driven at regulable speed, and contacts are made between a battery and the line at intervals which are controlled by holes punched in the moving band. For dot signals short contacts are made, followed by a reversal, while for dashes longer contacts are made, followed similarly by reversal. Direct-current dynamos are frequently used in place of batteries. Such periodic applications of E.M.F. to the line are characteristically rectangular in wave form, or square-topped as distinguished from being sinusoidal.

It was shown that the authors had produced a transmitter in which by suitably punching the paper band, the signalling currents could be obtained from a small alternating-current dynamo, a dot being formed by a positive impulse, followed by its negative successor—*i.e.*, by one compete cycle; a dash is formed by a positive impulse, followed by two blank semi-cycles and a negative impulse —*i.e.*, by two complete cycles, with the middle two waves suppressed. These contacts are made by a pair of small brushes resting on a metallic drum with the intervention of the punched paper strip.

The contact apparatus is mounted in an extension of the shaft of the little alternator, so as to ensure the making and breaking of the circuit through the contact brushes at the moments when the alternating current is zero. For long lines and speeds not exceeding 100 words per minute the alternator may be bipolar, for greater speeds multipolar.

Instead of mounting the contact apparatus on the alternator itself, it may be mounted upon the shaft of a little synchronous alternating-current motor which drives the perforated paper strip, and which is itself driven by an alternator at any distance. By this means a number of different transmitters may all be operated from one and the same alternator.

The advantages claimed for the transmitter are:—

1. The capability of using higher transmitting voltages than at present, because there is no sparking at the contacts, these being lifted at the zero instants.
2. The greater speed that can be obtained on long lines, partly by the use of greater voltage, and partly by the use of sinusoidal voltages as distinguished from rectangular voltages.
3. The capability of giving the same speed to a number of different transmitters, and maintaining that speed indefinitely.
4. The absence of all transmitter batteries.
5. The simplicity of the apparatus.
6. The fact that the tape can be put into the transmitter upside down without affecting the transmission.
7. The elimination of repeaters by reason of the increased speed.

It was stated that comparative trials between the regular Wheatstone and the Wheatstone provided with this sinusoidal transmitter showed a gain of nearly 100 per cent. in favour of the latter. Tests were cited to this effect. It was stated that whereas a safe formula for ordinary Wheatstone was

$WKR = 10 \times 10^6$ where K = capacity of line in microfarads,
R = resistance of line in ohms,
W = working speed in words per minute.

The corresponding formula for sinusoidally operated Wheatstone was $WKR = 18 \times 10^6$, and this when not employing more than 230 volts of alternating-current pressure.

It was also stated that sine-wave transmitters have recently been installed upon the land line of the Commercial Cable Co. from New York City, U.S.A., direct without repeaters to the Atlantic cable landing at Canso, Nova Scotia, a distance of about 1,115 miles. The speed of transmission of the line thus equipped exceeds the entire carrying capacity of the Atlantic cables of this company.

* Abstract of a Paper communicated to Section IV. (Telegraphy and Telephony) of the International Electrical Congress, Paris, August 23.

ALTERNATING-CURRENT INDUCTION MOTORS.

BY A. C. EBORALL.

We give below a reprint of the discussion which followed the reading of the above Paper at the Institution of Electrical Engineers on May 17th last. The official report of this discussion having already been published in the *Journal*, and several speeches having been considerably modified under revision, it has been suggested to us that we should reprint this official report in place of our own report of what was said at the meeting. We have therefore followed out this suggestion, which will explain the departure, in this particular instance, from our usual custom to report in the third person.

DISCUSSION.

Mr. M. B. FIELD: Mr. Eborall commences his Paper with an apology for bringing before the Institution one which he says contains but little that is really new from the technical point of view. Now, I venture to think that this apology is quite unnecessary, for I believe I am right in saying that many of the ingenious devices which Mr. Eborall has explained to us to-night, although perhaps not new, are new to many of us; at any rate, they were to me. The Paper contains a large amount of information which is extremely useful, as well from the manufacturers' as the users' and theorists' points of view. The method of building up the stator core described by Mr. Eborall whereby all tooling is rendered unnecessary is very interesting. But it is to be pointed out that one has to depend entirely upon the friction between the individual plates to avoid displacement of the same, or rotation of the stator core as a whole. Where paper insulation between the core discs is employed, some 15 per cent. of the total space will be thus occupied, and with the

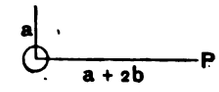

FIG. A.

continual heating and cooling of the motor this may shrink, and thus tend to relieve the friction between the end plates; consequently for large-sized motors this construction is not suitable. The question of tooling the stator cores is very important, but it is not very important whether the rotor core be tooled or not. The slip is very small, and hence the eddy currents produced in the rotor surface will likewise be small; moreover these will not be detrimental, but will add to the torque rather than decrease it. The figures on page 676 ("Notes on Performance and Design") are very instructive, but I would suggest that the author adds in his Paper when printed in the *Journal* the corresponding figures for continuous-current motors. I know this does not exactly fall under the heading of the Paper, but a comparison would be so very interesting that the departure would be quite warranted. The comparison between the efficiencies of polyphase and single-phase motors is also noteworthy. We must remember that a given rotor developing a given H.P. has twice the C^2R rotor loss if in a single-phase field, to what it will have in a three-phase field of the same strength; so that in order to get high efficiency in the single-phase case one can only do so at the expense of extra material, which fact, I think, is borne out by the table of weights given on page 676. From this it appears that the weight of the single-phase motor is about 50 per cent. higher than that of the corresponding polyphase motor.

I should like to make a few remarks with regard to the starting of the Heyland motor, as it seems to me that this is a radically new departure. I have always been under the impression that it was of no advantage to make the starting field larger than the working field, the aim of the manufacturer being to obtain as nearly as possible a pure rotating field at starting. This, of course, is not the case, as is easily seen by the following diagram. Let a be the strength of the alternating flux produced by the working phase winding, and $(a+2b)$ the corresponding flux produced by the starting winding. Suppose these two fluxes are in quadrature both as regards space and time. If we combine the working phase flux a with a portion of the starting flux equal to it in magnitude, we get, of course, a rotating flux of strength a, and superimposed upon that an alternating flux of strength $2b$ in the direction OP. Now, this latter flux we may consider replaced by two rotating fluxes, each of strength b, rotating in opposite directions with the same velocity, viz., that corresponding to the frequency. Further, these two fluxes b will coincide and be directed along OP at the same instant that the rotating flux a lies in this same direction; in short, the resultant of the working and starting winding fluxes will be a forward rotating flux of strength $a+b$, and a backward rotating flux of strength b.

Digitized by Google

When the motor is starting the speed of rotation of these two fluxes is the same, and since each pulls on the rotor, the one forwards and the other backwards, with a force proportional to the square of itself, we get for the resultant starting torque an expression proportional to $(a+b)^2-b^2$ or $a\ (a+2b)$. In other words, the starting torque is proportional to the product of the two fluxes, which shows us at once the advantage to be gained by making the starting flux large. If the two fluxes are not 90deg. out of phase with one another, but differ by the angle ϕ, then the starting torque is proportional to $a\ (a+2b)\sin\phi$. Mr. Eborall says that in the Heyland motor ϕ may be 50deg.; assume it to be only 45deg, then we see it is only necessary to make the starting flux 1·4 times the working flux in order to obtain precisely the same starting torque as would be obtainable in the corresponding two-phase motor. We may say briefly, if A and B be the working and starting fluxes respectively and ϕ the phase difference, they represent, as far as their starting capabilities go, a rotating flux of strength $\sqrt{AB}\sin\phi$.

With regard to the method of winding the Heyland motors for the purpose of altering the number of poles, it seems to me that the Paper is not quite clear. Mr. Eborall says: "On the other hand, the method of altering the number of poles has two serious disadvantages. Firstly, the reduction of the number of poles causes an unfavourable distribution of the magnetic flux, a large increase of magnetic leakage and a loss of winding space. This is of course owing to the fact that after the reversal of the appropriate coils the currents flowing down one side of those coils are neutralised by the currents in the adjacent side of the unreversed coils, as will be readily seen from Fig. 14, illustrating the single-phase case." Now this is not necessarily so: at least it is entirely a matter of arranging the winding so as to have as many coils as poles, or as many coils as pairs of poles. In Fig. 14 we have four coils—that is to say, we have as many coils as poles, and that is the reason why part of the winding is neutralised when the two coils are reversed. If we change that winding and put as many coils as pairs of poles, making two coils instead of four, we shall find the

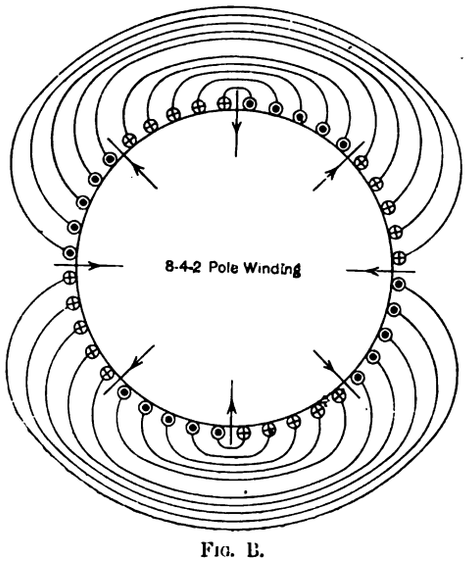

FIG. B.

windings are not neutralised when we reverse one coil. Fig. 16 shows this very well. This winding is not particularly a Heyland winding, but merely a normal winding with as many coils as pairs of poles. On the right-hand side there is an eight-pole winding with four coils. When we reverse two of the coils we get four poles. The Heyland winding corresponding to Fig. 18 for that case would be as shown in Fig. B. Fig. 18 shows a twelve-pole winding. If the connections of the coils be altered, we can get a six-pole or a four-pole or a two-pole winding. In the above diagram we can get an eight-pole, a four-pole, or a two-pole winding by similarly altering the connections between the coils. Fig. 16, on the other hand, shows an ordinary winding which has been known and employed for a very long time. It differs from the Heyland arrangement in that the only variation possible is 8-4 poles. We have, in fact, as above stated, an eight-pole winding with as many coils as pairs of poles. We can therefore reverse half, and get half the number of poles with none of the windings neutralised, thus obtaining as many coils as poles. If we were again to reverse half the poles, half the winding would be neutralised. The only variation feasible is thus from eight to four poles. That is the main difference between this and the Heyland winding shown in above diagram.

Mr. LANGDON DAVIES: There are one or two matters which I should like to refer to. The author says, "With single-phase motors which are usually arranged to start up light, wound rotors with slip rings should be used over 7½ B.H.P.," but he does not appear to give any explanation why this should be. I have seen larger sizes without them, and should therefore be obliged if the author would kindly give his reasons. With regard to one particular type of motor the author says: "The winding carrying the current of greater phase difference is made to have the smaller self-induction." I do not understand, considering that there is nothing exterior to the coils, what produces the "greater phase difference" if it has the smaller self-induction. It may be that he and I attach different meanings to the term "self-induction." Later he says: "The production of a rotary field on starting is not aimed at." This appears to require explanation, because a rotating field is absolutely necessary to start an induction motor of the type described. Also a considerable phase difference, I believe 50deg. or more, is claimed later on. The form of stator winding described is interesting, and appears to save turns. I should like to know if the author can give any details of starting torques for given current values without any resistance in the rotor; that is to say, with an ordinary short-circuited rotor of any type. These would be interesting, as they would show the difference produced by this stator winding, irrespective of the addition of resistance to the rotor windings, which is not new. The Paper is an exceedingly interesting one and raises many points for discussion.

Mr. W. G. RHODES: I have listened with very great interest to Mr. Eborall's Paper. It deals with a subject which has not for some time been brought before the notice of the members of this Institution, and one which certainly deserves more attention than it receives in England. It is, in my opinion, a subject which will eventually have to engage our attention, whether we will or no. There are, as Mr. Langdon Davies has pointed out, some rather peculiar remarks in the Paper which require elucidation. One regarding self-indnction, on page 677, perhaps may be explained in this way. I think that Mr. Eborall is rather misusing the term self-induction, because, in my opinion, the coil has a *larger* self-induction. The self-induction of a coil when there is another coil near to it is the number of lines of force which link that coil only and escape the other. Now Mr. Eborall distinctly states in his Paper that the starting coil is wound in such a manner as to produce large leakage. That large leakage, I take it, is the self-induction. The Heyland motor is wound so that the running coil has a minimum leakage—no self-induction—if possible, while the starting coil has a large leakage, that is, a large self-induction. The reason why a better result should be obtained with a small number of turns on the starting coil is that a larger current is allowed to pass, producing a large useful flux, or mutual induction, and at the same time a large self-induction to displace the current out of phase with the impressed potential difference. I prefer to view these problems rather from a physical aspect than from a mathematical one, although I have often looked at them from both points of view. On page 676 the flux density in the iron is given; I imagine that it is rather too high. In transformers it is not customary to go up to 10,000 lines or even to 5,000 lines per square centimetre, on account of the large hysteresis loss. An induction motor is like a transformer, and the stator is subject to the full frequency of the supply circuit, so that, in order to keep the efficiency of the motor within reasonable limits, it is advisable to keep the induction density moderately low.

With regard to Mr. Eborall's statement as to the standisation of periodicities and voltages for alternating-current motors, one cannot say too much in favour of it, because the want of such standardisation is undoubtedly the manufacturer's bugbear.

As to the possibility of starting monophase induction motors under load, it seems to me that too much attention has been devoted to the stator windings. Undoubtedly the Heyland winding is an extraordinarily good one; we will not dispute that. It produces good results. We are told that the phase difference between the starting current and the running current is about 50deg. The two mutual fluxes, the mutual flux of the running coil and rotor and the mutual flux of the starting coil and rotor, should approximately produce a uniform rotating field. The leakage flux of the starting coil should displace the current in it as much as possible, the nearer 90deg. the better, though of course this value cannot be attained, but the greater the displacement of phase the better it is for starting. If further improvement is to be made in the starting of such induction motors, we shall have to look to the rotor. The Heyland motor is, as far as the rotor is concerned, worked by inserting at the start a resistance into each of the three circuits. The object is to cut down the rotor currents at the start, because the rotor itself has a large self-induction, producing a large leakage field—a large field which does not cut the stator running coil. The insertion of resistance into the rotor circuits diminishes the leakage field, which, by its demagnetising action, tends to nullify the effect of the stator magnetising current, but it also diminishes the rotor energy current, which is in phase with the E.M.F. induced in the rotor coils and which produces the torque. What we ought to do, if possible, is to wipe out the self-induction of the rotor coils completely, in fact, to have no self-induction of the rotor coils, no self-induction of the running coil, and a large self-induction of the starting coil. It is impossible to wipe out the self-induction of the rotor coils by means of a non-inductive resistance to start with, and to put in an inductive resistance to start with is worse, because that will throw the current more out of phase with the induced E.M.F. I have tried myself to nullify the effect of the leakage field due to the rotor currents themselves by the injection in the rotor circuits of counter E.M.F.s which will act in opposition to the leakage field produced by the rotor currents, and I have got very fair results from it. For instance, I have got a motor to start with full-load torque with approximately 1½ times full-load current. That is not very good, but it is fairly so, and may probably be improved. I have now in process of manufacture by the Clayton Engineering and Electrical Construction Co. (Ltd.), a two-horse induction motor for 50 cycles and 200 volts, and I am anticipating that the starting current will not much exceed 13 amperes. The counter E.M.F.s are obtained by tapping the stator circuits in a suitable manner and connecting through a suitable switch with the rotor collector rings. It can be done by using transformers with negligible leakage. The necessity of having little or no self-induction of the rotor coils and running coil is obvious when we consider the low power factor of alternating-current motors. When we cannot get more than about 75 per cent. power factor, it shows that the leakage is considerable.

We cannot consider the alternating-current motor, either polyphase or monophase, anything like perfect until we can have at the same time a

Digitized by Google

frequency changer. The present method of changing the speed is altogether crude and unscientific. It does not admit of any gradual change of speed at all. It can jump from one speed to another and back again suddenly, but the gradual change of speed is impossible with the present means. The only means of doing that and of obtaining the results which we hope to do with induction motors, is by the introduction of frequency transformers giving a very wide range of frequency.

Prof. ERNEST WILSON: Mr. Hurst has prepared some curves for me which are shown in the accompanying diagram. The data from which those curves have been obtained were supplied to me by well-known manufacturers of induction motors. In the diagram vertically the weight of the motor, suitable for belt-driving, is given in pounds, without reckoning foundation rails, starting resistances or anything external to the motor. Horizontally is plotted a quantity which I once ventured to call a "mass factor"—that is to say, it is the B.H.P. of the motor divided by the revolutions of the motor per minute. The curve A refers to a single-phase motor suitable for working at a frequency of 50 periods per second; the curves B, C, E and F refer to multiphase motors at 50 periods per second; whilst the curve D refers to multiphase motors at 60 periods per second: the data being such that the curves are comparable with one another. The dotted curve a refers to direct-current four-pole motors made by a well-known firm, and is included for comparison with the curves which have been obtained from the induction motor data. I should like to point out that different makers have widely different ideas as to what the weight of a motor should be for a given mass-factor. For instance, taking a mass factor of 0·1, the weight may vary through very wide limits, according to the ideas of the several makers; and this, I think, is an important matter. The prices of these motors have been plotted in terms of the

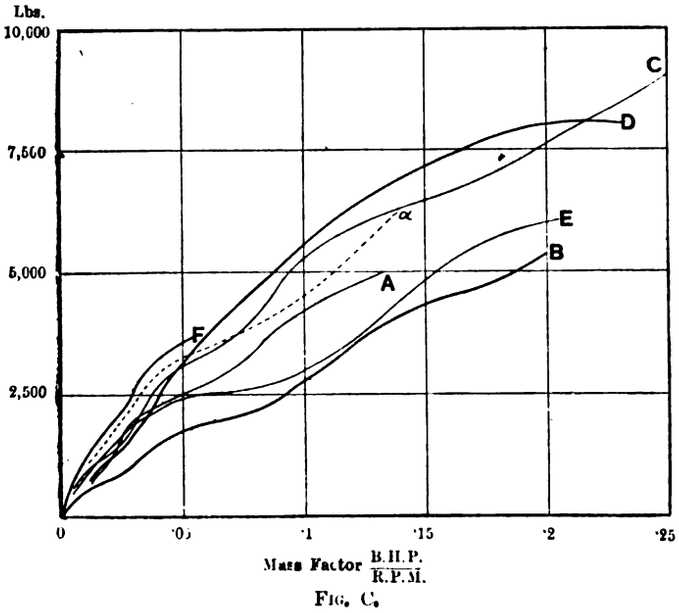

FIG. C.

mass factor. I have not got the diagram here, but there is not such a great difference between the prices as there is between the weights. In conclusion, I wish to congratulate Mr. Eborall on presenting such a valuable Paper.

Prof. C. A. CARUS-WILSON: The most interesting part of this Paper is that relating to starting devices for single-phase motors, I have endeavoured to make out from Mr. Eborall's Paper exactly how Mr. Heyland's device works, but it is not easy to ascertain what is the real action producing this result, and the difficulty is increased by the way in which Mr. Eborall uses the word "self-induction." The problem of the single-phase induction motor point is to get a strong field lagging well behind the primary field. One way in which this has been attempted is, as Mr. Eborall has indicated, to use an outside choking coil. The disadvantage of this method is that while you get a good lag you waste your field—that is to say, the flux in the choking coil is no use for producing torque, or, as Mr. Eborall puts it, "the strength of the cross flux, *in the motor*, is diminished by an amount equivalent to the leakage flux of the coil." If, on the other hand, you try to get your lag by using a starting coil of large self-induction, you find that the effect of the self-induction is neutralised by the reaction of the currents in the rotor, so that you have a strong field but a poor lag. What Mr. Heyland has done is practically this: He has taken a single-phase motor with the usual starting coil and no outside choking coil, an arrangement which, under ordinary circumstances, would give you hardly any starting torque, and he has allowed some of the useful flux of the starting coil to leak, by providing it with a carefully designed leakage path, and this leakage flux is enough to give a good lag. It is true that by permitting leakage he weakens his field, but in doing so, he gets a field out of step with the torque-producing field, and in that way he is able to get a good lag. I think that the real discovery Mr. Heyland has made is that it pays to take away part of the total field of the starting coil, when by so doing you can make it leak, and thus get a good lag. As to the reason why it is found advantageous to have but few turns in the starting coil, it seems to me simply a question of ohmic resistance, since by lowering the resistance you can increase the lag that you get for any given self-inductive effect. Mr. Heyland has certainly obtained good results, that is to say for single-phase motors, namely, a full-load starting torque with twice the full-road current. Looking at the diagram on page 811, one sees in the first place that the speed regulation is good for a motor of that size: in fact the speed regulation of a single-phase motor is in general better than that of a polyphase motor. The efficiency is very fair as shown by the diagram. The great defect is, no doubt, the low power factor. Few things are more provoking to the electrical engineer than lagging current. One feels that it is not doing the least good, and yet you cannot get rid of it. Of course with a single-phase induction motor all the bad effects due to lagging currents that you get in the polyphase motor are intensified, since the primary current has to carry the magnetising current for both the main field and the cross field, and consequently you get a very low power factor, as shown in the diagram, something between 50 per cent. and 60 per cent. at half load. Electrical engineers have made great efforts to increase the value of the power factor. In this connection it is difficult to avoid mentioning the name of Mr. Steinmetz, the Clerk Maxwell of alternating-current engineering, since it is almost impossible to say anything about induction motors that has not been written or said by Mr. Steinmetz. It is not, I think, out of place to refer to the remarkable discovery—as I think it may be called—quite recently made by Mr. Steinmetz of the single-phase condenser motor. In the course of experiments Mr. Steinmetz found that if in a single-phase induction motor you connect the starting coil, called by him a tertiary coil, to a condenser of suitable capacity, it can be made to supply the magnetising current for the cross field, thereby relieving the primary of the burden of supplying that current, and thus raising the power factor to that of an ordinary polyphase motor. Further, by increasing the capacity of the condenser, not only can it be made to supply the magnetising current for the cross field, but also that for the main field. In this way the condenser actually supplies the whole of the magnetising current, and the power-factor is raised to 100 per cent. It is true that this gives no advantage at starting, it simply enables you to run at synchronism with a high-power factor. Mr. Steinmetz gets his starting effect by shifting the tertiary or starting coil round through a certain angle. This seems to have led him to the idea of applying this method to an ordinary three-phase motor, that is to say, simply to put the condenser across one of the three-phase connections. In this ways he gets a good starting effect—though not as good as when the motor is running on a polyphase circuit. Not content with putting a condenser coil across one of his three-phases, he puts a reaction coil across the other, and finds that he is able in this way to make the starting torque and the output of a single-phase induction motor as high as could be obtained if the motor were running as a three-phaser, and at the same time with a power factor at synchronism of over 97 per cent. I think that is a remarkable result. It will be said that with this system you have to use condensers, and that there are serious objections to this. No doubt there are objections to condensers, but like many other objections they may perhaps be got over. In any case I think Mr. Steinmetz may be congratulated upon his achievement.

Mr. S. Z. DE FERRANTI: I have followed this Paper with the greatest possible interest, but the concluding remarks interested me even more than the Paper, because in them the author says that single-phase supply is practically played out. Well, if that is so, I think it is a very great pity to have taken up the time of one of the Institution's meetings with a Paper about single-phase alternating-current motors. So far as I can see, single-phase alternating supply is only just commencing, provided it is carried out in the right way. I do not say that to-day for a large power scheme I should feel inclined to lay down a single-phase system, but I feel confident that in less than a year's time we shall be planning single-phase power schemes for all purposes. Indeed, to-day it would be very hard to get anything better than a single-phase power-supply for feeding a continuous-current network. I think it would be found the cheapest way of doing it through motor-generators, and I think it will be found the most efficient and generally the most satisfactory way. For town lighting, where there is a fair amount of motive power work, very excellent motors, among them that of Mr. Heyland, have made this quite a practical system, and there is very little superiority of the continuous-current for ordinary motor work over a low periodicity alternating. There is, of course, the question of running lifts, and motors of that class still require a satisfactory solution. I am, however, quite confident, and that apart from what we hear that Mr. Steinmetz has done, that there will be before long commercial single-phase motors on the market with a power-factor of very nearly unity, and an efficiency of about 90 per cent., or even more, in ordinary practice. With regard to what we have heard about Mr. Steinmetz, it seems strange, since the problem is solved, that we do not see the result of the solution on the market. As a matter of fact, I do not think Mr. Steinmetz was at all original in the work that we have heard attributed to him. Who really started this idea I do not know, but I saw eight or nine years ago a motor fed on a single-phase circuit running practically as a two-phaser and using a condenser on one circuit which gave all the results that we have heard of, and yet that motor is not on the market. I suppose the reason is because one of the elements—the condenser—is commercially wanting. If we had the condenser it would settle a great many problems and improve a great many rather awkward positions. No doubt the demand will bring forth the article sooner or later, and I hope sooner. With regard to the question of single-phase motors as applied to the production of power in cities, ordinarily, I think that engineers running single-phase installations need not feel in the least uncomfortable or anxious about the future of their installations, provided they are of low periodicity. We have heard, as I said before, that this class of work is played out; but, on the other hand, I think this class of installation is just commencing its real career of usefulness. Still, I would like to point out that high-frequency installations are at a very great disadvantage, and whatever improvements are made in the way of motors and in the way of running these systems

Digitized by Google

generally, I do not think that they will ever get to be as satisfactory commercially or as good generally as low-periodicity single-phase systems. There is no doubt that the low periodicity greatly assists the motor question besides many other questions, and I think that when we have got the few additionol developments which are still wanting we shall see the bulk of power-supply and distribution work done with single-phase alternating currents.

Mr. W. B. ESSON: The large attendance at this meeting shows the great interest which is being taken in induction motors, and Mr. Eborall is to be congratulated on bringing this subject before the Institution. But in the short time at our disposal the matter cannot be discussed in the way it certainly deserves. I should like to say that I appreciate in the highest degree a remark made by the author at the end of the first part of the Paper, where he says "that experience in designing and a large quantity of experimental data for the type in question are absolutely necessary if the best results are to be obtained." If you devour the whole literature of the subject the feast will not enable you at the first trial to design a good induction motor, and I think every designer knows that. Coming to the points of construction, I am very interested in Mr. Eborall's way of building up the stator plates, but there appear to be some disadvantages which Mr. Field has already alluded to, and which may become accentuated in motors of large size. In the motors my firm has made we have fitted the plates right into the cast-iron stator cases. We find that we cannot dispense with the tooling, because the stampings are not good enough to enable us to have a uniform gap of $\frac{1}{16}$in. with plates of 12in. diameter, without tooling inside. Mr. Eborall puts the matter in this way. He says: "I cannot use the hole stampings, because if I do I have to tool them, as the shred of iron left must be very small." On the other hand I put it this way: I have to use the hole stampings for small motors, because there is no other kind I can tool. If I have slotted stampings they cannot be tooled, because they burr up. There is a question in my mind as to whether the stators with the straight slots, as made by the American companies, notably the Westinghouse Company, or the stators with the hole winding made by the Continental firms, are the best. The one has certainly all the coils wound on formers, and you get a perfectly symmetrical winding, and a winding, I think, which should be easier to repair than the hole-wound stators, where you have bent coils and straight coils alternately. It is a very important point in sending motors abroad, where no technical skill can be found—or, at any rate, the technical skill is of a very low order — to have motors that require no repair, or very little repair; and when they do want repairing the repairs ought to be able to be performed in the easiest possible way. On page 644 Mr. Eborall refers to the starting of the motors, and he says: "For motors having to start against load (apart from crane, elevator, and mining motors) the author is decidedly of opinion that the squirrel-cage construction, or its modifications, should be avoided with all polyphase motors about 5 B.H P." That, I believe, is the Continental practice. Motors with squirrel-cage windings are not usually made above from 5 H.P. to 10 H.P., though I have got some firms to make them as high as 22 H.P. On the other hand, the American practice is quite the reverse. There they make motors of any size with squirrel-cage windings. The largest I have had was from the Westinghouse Company—a 50 H.P. with squirrel-cage winding, and it gave every satisfaction. I should like to hear more fully the author's reason for limiting the size of a motor with a squirrel-cage winding to such a low power as 5 H.P. It must be remembered that a wound rotor is much more expensive. In the case of a wound rotor you want, probably, four times the amount of copper to get the same result, and with the wound rotor you have a somewhat smaller power-factor. Coming to the figures which Mr. Eborall gives of the performance in "Notes on Performance and Design," in my Society of Arts Paper, read in 1897, I gave some figures of the power-factor. These were not the same as those of Mr. Eborall, and they differ in this way, that Mr. Eborall's figures are, I understand, guaranteed performances, whereas mine were actual performances. There is a very great difference. I have had the figures for power-factors, which Mr. Eborall gives specified and also guaranteed, but I have never got them. I can tell you what is given by the very latest and best practice on the Continent. I have had an opportunity of testing all sizes of two-phase motors, from 5 H.P. up to 100 H.P., and the very best power-factor we ever got with a 15 H.P. was 81 per cent. (that was with a squirrel-cage winding), with 25 H.P. 78 per cent., and with 100 H.P. 80 per cent. They were two-phase motors, with a frequency of 50. While therefore I am a great believer in the induction motor, I am no believer in Mr. Eborall's figures. That, I think, is all I have to say on the motor question. There is one point which has been referred to by Prof. Carus-Wilson, namely, the question of condensers. I should like to hear from Mr. Eborall whether latest advices from the Continent and America on the subject show condensers to be commercially successful. Several years ago the Stanley Manufacturing Co. in the States introduced as an ordinary thing in their catalogues condensers for working with two-phase motors, but I never heard whether they had been successful commercially or not. I should very much like to have some information upon that point.

Mr. G. L. ADDENBROOKE: I think Mr. Eborall is to be congratulated on the manner of his Paper, as well as the matter. It seems to me that he has presented the whole subject in a very well-balanced way. There is one point with regard to the power-factor which I should like to allude to, following on what Mr. Esson has said. It appears to me that the wattless current taken by motors, though not actually constant, is more or less a sort of constant over a considerable range, and it would be very useful if, in the figures he has given us, Mr. Eborall could split up this no-load current into two factors, the watt current actually taken for friction and magnetising the iron, and the actual wattless current required to produce the field. These figures are very useful, because if you have that constant for no load it enables you to get an approximate figure for the power-factor for any other load. I do not say that it is absolutely so, because leakage comes in with a heavy current, but it certainly gives a very useful approximate figure.

The only other point I wish to deal with is the question of single-phase *versus* two-phase or three-phase. It is rather unfortunate, when we are proposing to open out into this work, that this question should be raised again. I have spent some time in looking into the matter from a practical point of view, and it seems to me that it is difficult to form any very definite opinion on the subject, as one cannot go on any very clear-cut lines. You can get up to a certain point, after which we must speculate upon unexpected developments of some sort or other. Mr. Ferranti may know something which he has not told us which might modify our ideas, but I must say I cannot see anything on the horizon which would in the end make single-phase better than a two-phase or three-phase alternating-current for most purposes. Supposing we actually succeeded in making a single-phase alternating motor as good as a two-phase motor—to all intents and purposes—should we have a very great gain? Would it not still be better to have two-phase or three-phase? Are there not certain advantages in having two-phase and three-phase. I do not say in the motor itself, but in the whole system, which would outweigh a question of the apparent simplicity of single-phase? That is the point.

Mr. EUSTACE THOMAS: Mr. Eborall's Paper has raised many points of interest, but it will only be possible at this late hour to refer to one or two of them. The use of squirrel-cage rotors has been disparaged in a manner which is, I think, somewhat too general. There are many cases where a squirrel-cage rotor would produce objectionable disturbance even in a motor of only 1 H.P. or 2 H.P. On the other hand, there are cases where such rotors can be used with advantage in motors of 50 H.P. or more. Perhaps the only generalisation that can be made is that squirrel-cage rotors should be used in all the numerous cases where no serious disturbance will result, and where the other conditions are suitable; the engineer will have to decide each case on its own merits. An engineer cannot afford to get the reputation of being a "wound-rotor man," or a "squirrel-cage man," any more than he should allow himself to be considered a "continuous-current man" or a "three-phase man." Each system should receive application in its proper place.

In his "Notes on Performance and Design," Mr. Eborall gives values which are, I think, more applicable to the closed slot, or Continental design, than to the open slot American type. The latter undoubtedly has a larger magnetising current, but it possesses the advantages of form-wound, interchangeable windings, and seems to give somewhat better results as regards breakdown point, efficiency, and power-factor, although these do not depend only, of course, on the shape of the slots. In illustration of this, I may quote the following tests selected at random. The breakdown point of a 5 H P. motor occurred at 2·7 times full-load current, and of a 50 H.P. motor at 4½ times. Motors of intermediate capacities had values between. This is a matter of considerable importance, as the available torque varies as the square of the voltage, and such losses as commonly occur in distribution systems have frequently resulted in the motors failing to carry their load.

As regards efficiency, tests of a 5 H.P. motor showed 81½ per cent., and of a 15 H.P. motor 88·9 per cent. The 5 H.P. motor further gave a power factor of 87½ per cent. It may be that the values in the Paper are guarantees, in which case, no doubt, a factor of safety has been allowed, and the difference would not be so great. As further illustrating how motors of good design may differ, and still give good practical results, I may say that the air-gap on small motors may be larger, and on large motors smaller than Mr. Eborall's figures with good results.

The preceding discussion has made it clear that the Heyland motor starts in the same general way as other motors commonly used, and it is unnecessary to dwell at length on the matter. To Heyland is due the credit of seeing that a large field produced by the starting coil is an advantage, and that sufficient lag can be obtained in the coil alone, by bunching the windings and so shaping the slot that a considerable leakage path exists. Mr. Field's explanation of the value of the larger flux is new and interesting.

The question has been raised by several speakers as to the possibility of using condensers commercially with single-phase motors. I am able to say that they have to my knowledge been used for some time past with success. After what has been said, the Institution may be interested to hear some of the results obtained on the commercial, as distinct from the experimental scale. A 5 H.P. motor gave a power factor of 90 per cent. and an efficiency of 80 per cent. It further started with full-load torque at 1½ of the full-load current. The advantages of the system both as regards starting and running will thus be apparent, and should make it possible to use such motors on existing lighting circuits, having poor regulation on account of (magnetically) leaky transformers, or other cause.

Prof. CARUS-WILSON: Was a reactance coil used?

Mr. THOMAS: No. The motor may be described as a three-phase motor, the single-phase line circuit being joined direct to two terminals of the motor, while the third motor terminal was joined to one side of the single-phase circuit through a condenser. The condenser remains in circuit, and the motor with its condenser is treated as though the circuit were three-phase. In this case there is no starting coil to be cut out, but the whole of the winding is available both for starting and running, and hence the motor may be considerably smaller than the ordinary single-phase machine. This is of interest in relation to Mr. Eborall's remarks on the subject of size, and in that it enables the cost and weight of the motor and condenser combined to be kept within limits. The shipping weight of a 5 H.P. motor with all starting gear was 610lb., but this contained a considerable proportion of packing, probably about 20 per cent. The advantages of good power-factor, efficiency, and starting are thus obtained without extravagant weight or expense. The system of speed regulation described enables the speed of the motor to be doubled, but intermediate values must be obtained by resistance in the rotor circuit. I have the results of tests made on motors with a variable number of poles some time

Digitized by Google

back, and it is evident, as might be expected, that the constants of the motor suffer. In the cases that have arisen in my own practice, a speed range of two to one has usually been the extreme limit, and the limit speeds have been seldom required, the motor usually running at some intermediate value. This unfortunately greatly moderates the value of variable pole speed control; but within their limited field of application, the devices of Mr. Heyland are ingenious and command respect.

Mr. A. C. EBORALL, in reply, said: I have to thank the various speakers very heartily for the honour they have done me in discussing the Paper, and for their appreciative remarks. Several questions of considerable interest have been raised, and regarding these I would like to reply as follows:—

Mr. Field thinks that the method of building up the stator core-discs of induction motors, employed by my firm and described in the Paper, may prove objectionable on account of the plates working loose under the continual heating and cooling to which they are subjected in the motor. I think Mr. Field will agree that his objection entirely disappears when I tell him that the rivets are put in hot. As stated in the Paper, however, the method is not so suitable for very large motors, and modifications are introduced for motors above 30 B.H.P.; up to this size it has proved thoroughly satisfactory, and several hundred motors so constructed have never given the slightest trouble. Mr. Field suggests that I should give some figures for direct-current motors relating to design and performance, for purposes of comparison with the induction motors. It is a little difficult to do this, because the figures for various makes of direct-current motor vary enormously, on account of the variation in design; with induction motors this difficulty does not come in to anything like the same extent, as the general design is practically the same with all makers. But I may say that, generally speaking, the efficiency figures guaranteed by different makers for semi-enclosed direct-current motors are about the same as those given in the paper for polyphase motors, and the same remark applies to the heating. But the overload capacity is much less, and the weight per B.H.P. considerably greater for such motors, compared with the figures for polyphase motors. I am sure we are all indebted to Mr. Field for his very clear proof that in order to get the greatest possible starting torque with a single-phase motor, it is necessary to make the flux of the starting coils much greater than that of the running coils, and that it is not necessary to aim at the production of a uniform rotating field at starting. Mr. Heyland arrived at this result in quite a different manner, his method being not nearly so simple as that of Mr. Field, but it is curious that this important point should have been missed by every other designer of single-phase motors. Mr. Heyland saw some years ago that the idea of two equal fluxes at starting was fundamentally wrong, because the current in the starting coils of the single-phase motor cannot be made by any known means to have a lag of anything like 90deg. (as with the second phase of a two-phase motor), and he proved that by allowing the starting flux to be stronger than the flux of the running coils by a definite amount, it is possible to imitate the starting conditions of a two-phase motor, which is, as Mr. Field says, a radically new departure in single-phase motor design. The result has been that the Heyland motors are far and away ahead of any other single-phase motor with regard to the value of starting torque obtained with a given current consumption. Mr. Field's remarks on the Heyland speed-changing device are perfectly correct, and may serve to make that portion of the Paper referred to somewhat clearer.

Mr. Langdon Davies asks for my reasons for stating that single-phase motors above 7½ B.H.P. should be furnished with slip-rings. My own experience in this matter has led me to this conclusion chiefly on account of the better starting and greater overload capacity (particularly the former) brought about by the employment of wound rotors and a non-inductive resistance. I have found that with a given single-phase stator winding, a wound rotor used in conjunction with a non-inductive resistance will start and run up to speed with 12-20 per cent. less current than any pattern of permanently short-circuited rotor, and, moreover, owing to the better distribution of current in the bars of a wound rotor compared with that in the bars of a rotor of the squirrel-cage type, the overload capacity is considerably greater. Again, a rotor with a permanently short-circuited winding is far more likely to have dead points at starting when used in a single-phase motor, which is perhaps the reason why the current consumption is greater. Slip-rings (normally short-circuited) give so little trouble, and cost so little, that I certainly think wound rotors are preferable. I may mention in this connection that the Heyland motors have wound rotors and slip-rings in all sizes, that is, from ¼-100 B.H.P.; and, also in reply to a question of Mr. Langdon Davies, it has been found with these motors for 40, 50 and 60 cycles, that running up to speed without load, the starting current is four-fifths of the full-load current when wound rotors are used, and at least equal to the full-load current when the most carefully designed short-circuited rotors are used. In reply to the other remarks made by this speaker, I would say that the phase difference of 40-50deg. for the flux of the starting coils is caused by the great magnetic leakage this flux has, compared with the flux produced by the running coils. The large magnetic flux of the starting coils (caused by the large current in this winding of few turns) mostly leaks along a definite path, and this leakage produces the above-mentioned phase difference. At starting there is very little rotary field, the field of the motor being more of the nature of a purely oscillating field, and the result is exactly as shown by the Paper and by Mr. Field.

In reply to Mr. W. G. Rhodes on the question of the action of the Heyland motor, and also to Prof. Carus-Wilson's remarks as to this, I am aware that the explanation given in the Paper is, to a certain extent, incomplete, but it had to be curtailed as the Paper was getting unduly long. I am sure, however, that the ideas of most of those present to-night will be fairly clear on this subject, after having heard the remarks made by different speakers. The action of all single-phase motors and their starting devices can be looked at from several totally different points of view, and most of those who have gone at all deeply into the subject get perfectly clear ideas about it, which may be and generally are very difficult to put on paper in a few words. Mr. Rhodes thinks that the values for the flux-densities given by me for induction motors are somewhat high. I put it forward, however—I think for the first time—that in order to get large overload capacity with induction motors, and particularly with single-phase motors, the flux-densities in the iron parts, particularly in the stator cores and teeth, should be carried to a very high value; the increased iron losses can be counterbalanced by allowing for smaller copper losses, but, as a matter of fact, the increase in the iron loss by forcing the material in this way (and using less of it), is not very much, at any rate not enough to affect seriously the efficiency at light loads. In my opinion the two most important points in the design of induction motors are the selection of the flux-densities, and the shape of the stator and rotor teeth, and it is more important to design the teeth properly than even the air-gap. Regarding the point now under discussion, we have found by actual test on many single and polyphase induction motors of various sizes, that very much better results are obtained when the flux-densities in the teeth and cores are forced than when they are not, and you will notice in the motors shown to-night that there is wonderfully little magnetic iron in them. With these motors, the overload capacity is 50 per cent. to 60 per cent. with constant pressure at the stator terminals, and I think that those present who are used to single-phase motors of other types will agree that this large overload capacity is much more than they have been accustomed to, and that it is good enough. On the other hand, you may think that if this question of flux-density is really so very important, why do I not keep it to myself.' My reply to this is that the fact of having the right flux-density in the iron does not necessarily mean that the motor will be good; a very great deal depends upon the arrangement of the iron parts, upon the proportioning of the teeth, &c., and regarding these things every designer has to make his own experience. I am greatly interested to hear about Mr. Rhodes' recent work in single-phase motors, and look forward to seeing his motor on the market in due course. If this motor will really start with full load torque, with a current not exceeding the full-load current, as indicated, and if this result is attained without excessive complication and cost, then the Rhodes motor will certainly be a very formidable rival to the Heyland motor, as this latter stands at present. But I may say that Mr. Heyland is continually making improvements, and even better results will be obtained in the immediate future.

Prof. Ernest Wilson's curves are instructive, and with regard to them I would remark that in my opinion the curves B and E best represent good modern practice in polyphase motor building, and that the motors represented by curves D and C are unduly heavy for their output and speed. It is interesting to note from the curves that the line of direct-current motors whose weights have been plotted are heavier than the single-phase motors represented by the curve marked A.

I have already partly replied to Prof. Carus-Wilson, and with regard to his remarks on the power-factor of induction motors I thoroughly agree. Most designers of these motors are constantly striving to improve the power-factor, especially at light loads, and in this connection it would certainly appear that Mr. Steinmets has met with considerable success—at any rate in the testing room. Whether his method of shunting the windings by a condenser, which, by the way, is quite old, will ever prove of use commercially is open to question, as in my opinion a commercial way of building a condenser for continuous service has yet to be found.

Mr. Esson's criticism regarding the building-up of our stator cores has been already met; and regarding his remarks on the tooling of cores, while admitting that the difficulty of tooling stampings with open slots is a very real one, especially for the case of small motors, I must say that, in my opinion, it can be got over. Several Continental firms using this form of stamping invariably tool the stators in all sizes, without burring the teeth, the only disadvantage being, as pointed out in the Paper, a considerable increase in the iron loss. I agree with Mr. Esson's remarks on the subject of using former wound coils for stators and rotors, when the motors in question have to be shipped to places where skilled winders are at a premium, but for ordinary work I consider the employment of straight slots and former wound coils a mistake. You have to balance ease of repair and saving of labour in winding against a large magnetising current and diminished power-factor, especially at light loads, to say nothing of inferior starting, and in the great majority of cases the latter disadvantages outweigh the advantages.

With reference to Mr. Esson's remarks on the subject of permanently short-circuited rotors, I can only repeat what is stated in the Paper on this point, and what I have already stated in reply to Mr. Langdon-Davies. At the same time, I cannot agree with Mr. Esson's statement that the use of wound rotors lowers the power-factor, and that such rotors require about four times as much copper as squirrel-cage rotors. The former is directly contrary to my experience, while the latter statement requires I think, considerable qualification. With large induction motors, whose rotors are wound with a three-phase cylinder winding, the extra copper required is, at the outside, 50 per cent.

I am in complete disagreement with Mr. Esson's remarks on the subject of makers' guarantees and regarding what he states to be the latest and best Continental practice in induction-motor performance. Although I am perfectly aware that the guarantees given by certain firms are absolutely worthless, I am equally aware that those given by others are well on the right side. The figures given in my Paper are, as stated, the average of the guaranteed figures of five well-known houses—one Swiss, two German, one American, and one Belgian—and the work of three of these firms is intimately known to me. Not only do I consider the figures in the Paper perfectly reliable, but I maintain, and am prepared to prove, that better figures are obtained every day in ordinary work. Regarding

Digitized by Google

the figures Mr. Esson puts forward for the power-factor of 50-cycle two-phase motors, as representing the latest and best Continental practice, I may say that I consider the figures quoted as being distinctly bad; I should certainly reject any 100-B.H.P. 50-cycle polyphase motor having a power-factor of 80 per cent. at full load. I may, perhaps, be allowed to say in this connection that I have recently put down two 100-B.H.P. two-phase motors in this country, which have a power-factor of 91 per cent. at full load; with these motors 90 per cent. was guaranteed, and 88 per cent. would have been guaranteed under penalty. So it would appear that Mr. Esson has been somewhat unfortunate in his selection of a manufacturer.

Regarding Mr. Esson's final remark on the subject of condensers, I can only say that I believe all condensers have been complete failures up to the present, when they have been used for continuous work. The great difficulty is with the heating, and consequent rapid deterioration of the dielectric, while they are bulky, heavy, and therefore expensive. On the other hand, liquid condensers give quite good results when used intermittently, such as for starting single-phase motors, but they, in common with other types, are unmechanical, and consequently objectionable. Such liquid condensers quickly go to pieces if continuously in circuit; moreover, their capacity alters in an extraordinary way as they heat up.

I could say a great deal in reply to Mr. Addenbrooke, but will ask him to allow me to reply to his first remarks only, as the discussion of the relative merits of single-phase and polyphase hardly falls within the scope of the present Paper. Mr. Addenbrooke asks me to split up the no-load current of an induction motor into its components, indicating the relative values of the two factors. I may say that for most well-designed polyphase motors of medium and large size, the watt component of the no-load current is somewhere about 10 per cent. of the wattless component. Thus, referring to the left-hand diagram in Fig. D (the triangle), C_W, the watt current required for friction, ventilation, hysteresis, eddy currents, and the small no-load copper loss, is 10 per cent. to 15 per cent. of C_M, the wattless magnetising current of the motor. The resultant of C_W and C_M, namely, C_0, is the no-load current of the motor, and this quantity is, as stated in the Paper, 20 per cent. to 30 per cent. of the full-load

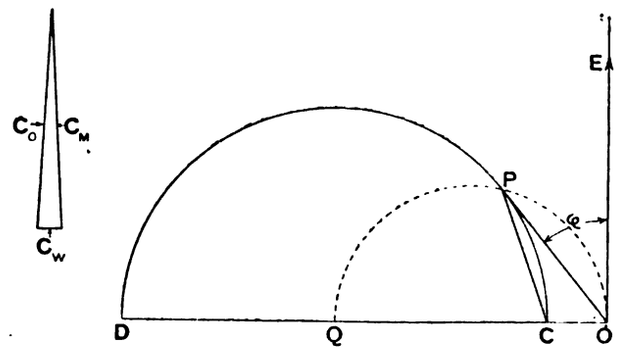

FIG. D.

current. As Mr. Addenbrooke says, knowing the magnetising current of an induction-motor (practically the no-load current), it is possible to predetermine the power-factor for any load. Fig. D illustrates any easy, graphical way of doing this, the diagram being constructed as follows:—

Let v_1 represent the stator leakage factor—that is, it is the ratio of the total magnetic flux produced by the stator ampere-turns to the flux that actually enters the rotor and cuts the winding *when the latter is open*. Similarly let v_2 be the rotor leakage flux—that is, the ratio of the total flux produced by the rotor ampere-turns to the flux actually entering the stator, and cutting its windings *when these are on open circuit*. Then write magnetic constant of the motor $= M = \frac{I}{v_1 v_2 - I} v_1$ and v_2 can be calculated, but are better found by a simple experiment. Their value lies between 1·02 and 1·07 for most makes of motor.

Referring now to Fig. D (which is the elementary diagram of the polyphase induction motor) set off the line OE to represent the phase of the applied E.M.F. per phase of the stator, draw the line OD at right angles to it, and set off along OD the magnetising current to scale, namely, OC. Now multiply this value of OC by the above constant M, and make CD equal to the value so found, the scale being of course the same as that of OC. Upon CD describe the semicircle CPD. Then all such lines as OP (that is, any point along the semicircle joined to point O) represent the stator current per phase in magnitude and phase, and all such lines as CP are proportional to the rotor current. The corresponding power-factor of the motor is given by the cosine of the angle ϕ. It will be seen that the maximum value of the power-factor occurs when the line OP is a tangent to the semicircle, as shown. For smaller and greater loads than corresponds to the value of stator current in question (OP), the power-factor diminishes, because the angle ϕ increases as the point P moves lower down or higher up the semicircle. The diagram clearly shows the effect of the magnetising current upon the power-factor of the motor, and also the effect of faulty design with regard to magnetic leakage.

With reference to Mr. Thomas's remarks, I think it would have been of interest had he told the meeting exactly what advantages are gained by building induction motors of large size with squirrel-cage rotors. Although I think with him that it is not possible to make hard and fast rules with regard to these things, particularly with regard to the relative merits of direct-current and polyphase working, still I think that after considerable experience with different conditions it is quite allowable to form and put forward an opinion. For instance, experience has conclusively proved that electric generators of any size should be direct driven, but it was not so many years ago that there was a very considerable amount of discussion on this point, and the early advocates of direct driving have now proved to be right. Regarding the point in question, it is clear to me that squirrel-cage rotors are inferior to wound rotors for all cases except those mentioned in the Paper, and I am confident that American constructors will come into line with those of the Continent before very long in this respect. It certainly seems to me that the apparent simplicity of the squirrel-cage construction (or its modifications) and the resulting advantages have been greatly overrated. There is an example of this at the Paris Exhibition, where an 800 H.P. induction motor, with permanently short-circuited rotor is being installed by one of the great American firms. This motor has to be run up to speed by a direct-current motor—a state of affairs bordering on the ridiculous.

Mr. Thomas's figures relating to the performance of induction motors confirm those I have given in the Paper, which, being guaranteed figures, of course are well on the safe side, as Mr. Thomas surmised. I would like to draw Mr. Esson's attention to the figures for these American motors, as they fully confirm what I have already said when replying to him.

[*Added, July 12, 1900.*] When replying to the discussion on the Paper I unintentionally omitted to reply to Mr. Ferranti, and therefore take this opportunity of doing so. I think if Mr. Ferranti were to reconsider his first remark, he would come to the conclusion that it is hardly fair. First, the Paper does not deal exclusively with single-phase motors, quite half being devoted to polyphase motors; and secondly, I distinctly state that the part relating to single-phase motor work is put forward simply as being of technical interest. Many men, including myself, *have* to take up the question of single-phase motors and single-phase systems, not because of any belief in their present or future possibilities, but because it is necessary to do so; but at the same time, this does not prevent the subject from being technically interesting both to them and to others. Mr. Ferranti's opinions on single-phase working are well known, and they are of the greatest value, because Mr. Ferranti has proved to be right on some of the most important points connected with alternating-current work many times before. At the same time, he does not give any reasons for his belief, and does not attempt to justify it in any way. But even with Mr. Ferranti's powerful championship of single-phase working, it is very difficult for those who have worked with single and polyphase systems to believe there is any advantage whatever in the former. Even in this country, many of the large single-phase systems are being converted into direct-current or polyphase systems, and all the most recent work of any magnitude is being carried out with either polyphase current, or a combination of this and direct current. My own opinion is that, as things are at present, continuous-current working is far preferable to any other for all large lighting schemes; and where it cannot be employed directly, it should be used, where possible, in conjunction with three-phase transmissions; or failing this, three-phase systems should be used throughout. For power work pure and simple, nothing can beat three-phase working, while for both lighting and power work, I am firmly convinced that the double-current generator (in combination with motor-generator substations) has a great future—that is, a special combination of the direct-current and three-phase systems.

THE BOILER EXPLOSION AT SYDENHAM ELECTRICITY WORKS.

A formal investigation was held at the Public Hall, Sydenham, on Aug. 30 and 31 and Sept. 3, under the Boiler Explosions Acts, 1882 and 1890, into the circumstances attending the explosion of a boiler at the Springfield Works of the Crystal Palace District Electric Supply Co. (Ltd.), on July 25 last. The investigation was held before Mr. Howard Smith, barrister-at-law, and Mr. J. H. Hallett, consulting engineer, Commissioners. Mr. Gough conducted the investigation on behalf of the Board. Dr. Kenrick appeared for Messrs. Hornsby & Sons (Ltd.), Mr. Willoughby Williams for the Crystal Palace District Electric Supply Co. (Ltd.), and Mr. Michael Longridge for the Engine, Boiler, and Employers' Liability Insurance Co. (Ltd.) and Mr. Charles A. Booth (their inspector). The boiler known at the works as No. 3 was of the locomotive type, and was made by Messrs. Hornsby & Sons in 1891 for a working pressure of 140lb. per square inch. The crown plate of the firebox was supported by seven girders, each being formed by two wrought-iron plates. At the ends of the seven girders were distance pieces with toes at their lower ends to fit on the vertical plates of the firebox. Each girder was supported by two hanging stays and the crown plate was attached to the girders by stay-bolts. The upper end plate of the shell was supported by 10 longitudinal stays, and, having regard to the position of these longitudinal stays and of the hanging stays, it was impossible to examine the fire-door or front end of the firebox without removing them. The boiler was originally insured by the National Boiler and General Insurance Co. (Ltd.), whose chief engineer's report on the inspector's examination of the boiler (dated March 8, 1898) was to the effect that externally the boiler was "in order." Of the interior condition the report stated:—

"No defects were met with, but the firebox stays prevented the inspector making closer inspection of the front part of the firebox. In the firebox the side plates are a little grooved at the edge of the firebox tube plate, also at the left side of the fire-door plate. The inspector states a test hole had been drilled at this latter place, but was plugged before his arrival. We understand the thickness was gauged by yourselves and found to be $\frac{7}{8}$in. Evidence of slight leakage was also noted

Digitized by Google

past the bottom corners of the firebox tube plate and past a small patch at the right front corner. A short fracture has developed at the left front bottom corner of firebox, and the boilermakers were repairing same. The firebox crown is generally a little bulged downwards, the deformation being more pronounced at the front end than other parts. . . . The defects in the firebox are not of serious importance, and doubtless the various leakages would be made good by the boilermakers. . . . We would suggest, if you have not already inserted the tubes (withdrawn for purposes of the examination), that you have the pins uniting the sling stays to the girders and to the double angles renewed. When all is complete we would advise that you have the boiler put under a water test pressure of, say, twice the working pressure."

The water test (but only up to the certified working pressure) was duly made by the Insurance Company's inspector who had recommended the double-pressure test, and the Insurance Company's chief engineer's report on the test was made on March 31, 1898, and was as follows:—

"The boiler was put under a water-test pressure of 140lb. per square inch. The firebox crown plate deflected under this pressure from about $\frac{1}{16}$in. to $\frac{3}{16}$in. Several slight leakages were also noted in the firebox. The test pressure applied is inadequate to enable us to form an opinion as to the value or tightness of the sling stays attached to the firebox girder stays, but so far as the test went it would appear that the sling stays or pins in their holes have become worn, and that they do not take up their full share of the load until material deflection of the firebox crown plate has occurred. We note that the deflection of the crown plate was only temporary, and that the crown plate returned to its original position when pressure was removed."

The evidence showed that the Crystal Palace District Electric Supply Co.'s chief engineer was held responsible for the upkeep of the plant, machinery, and boilers, a fitter being regularly employed to examine the boilers when cleaned out, about every five weeks. Some time after the date of the reports above set out the insurance of the Electric Light Company's boilers was transferred to the Engine, Boiler, and Employers' Liability Insurance Co. (Ltd.). The latter company, knowing that the boilers had previously been insured and annually inspected by the National Company, accepted the risk, stipulating for thorough examinations as opportunity offered. In April, 1899, the boiler was examined by Mr. Booth, inspector in the employment of the Engine, Boiler, and Employers' Liability Insurance Co., and as a result of that examination the company issued a certificate, available for 15 months, to the effect that the boiler was fit for a safe working pressure of 140lbs. per square inch. The boiler was subsequently examined by the fitter in the employ of the Electric Supply Co., who reported that it was in good working order. On July 25 the fire was lighted about 6:30 a.m. At 9:30 a.m. the steam was turned on to the engine, the pressure by the steam-gauge registering about 86lb. At 10 a.m. the pressure was 96lb., at 10:30 105lb., at 11 130lb., at 11:30 120lb., at noon 120lb., at 12:30 p.m. 125lb., at 1 136lb. at 1:30 124lb., and at about 2:15 132lb. At about 2:40 p.m. the boiler exploded. The crown of the firebox was blown out, the boiler was swung round and upwards through the roof of the boiler-house,* which, together with the upper portion of the outer side wall, was demolished, and, passing across the roof of the engine house, in an oblique line, fell into the garden of an adjoining cottage. William H. J. Philbrook was killed; Frank Elliston was so seriously injured that he died the same evening, and Charles Barker, Frank Chamberlain, Frank Tranter, Ernest Page, and Joseph Adcock were all more or less seriously injured. (The inquest upon the bodies of the men who were killed by the explosion was reported in *The Electrician*, Aug. 24, p. 681.)

DECISION OF THE COURT.

The finding of the Court of Inquiry was given on Monday. The Court held that the explosion was caused by the cast-iron toes of the distance pieces at the front end of the boiler having broken off, the load which should have been borne by the vertical end-plate being thus transmitted to the flange of that plate, causing the crown plate to deflect, and in doing so to increase the weight of the hanging stays, several of which had broken, and several were partly broken before the explosion. The Court were of opinion that the toes of the distance pieces were never properly bedded on to the plate, that the hanging stays were not properly constructed, and that they had been severely punished when fitted. That the boiler when new was not properly constructed, and it was not then fit for a safe working pressure of 140lbs. per square inch.

The Court found that the Crystal Palace District Electric Supply Co. had not appointed competent persons to attend to the up-keep of their boilers, their chief engineer being an electrical and not a mechanical engineer, but that if the company had followed the advice of the National Boiler Assurance Co. they would have taken reasonable precautions to ensure that the boiler was being worked under safe conditions.

The Court found that the examinations by the fitter in the employment of the Electric Supply Company were not thorough examinations, and that the fitter was not competent to make such examinations.

The Court found that the examination by Mr. Booth, in April, 1899, was not a thorough and complete one, that it was incumbent upon him to make a most careful examination, particularly having regard to the difficulty of examining the front end of the firebox. They were of opinion that if he had used a straight-edge he would have discovered the deflection in the crown of the firebox which existed in March, 1898, and that his failure contributed to the explosion.

The Court found that the explosion was caused by the electrical engineer failing to carry out the recommendations made by the National Boiler Insurance Co. as to the double-pressure hydraulic test in March, 1898, and in their opinion it was imperative that this test should have been made, having regard to the difficulty of examination.

The Court held the Crystal Palace District Electric Supply Co. (Ltd.) responsible for the neglect of their chief engineer, and the Engine, Boiler, and Employers' Liability Insurance Co. (Ltd.) responsible for the neglect of their inspector.

The Commissioners pointed out that the boiler was constructed nine years ago, and that if it had been thoroughly examined periodically, as it should have been, the explosion would have been prevented.

At the conclusion of the investigation Mr. Gough applied to the Commissioners to order the costs and expenses of the investigation to be paid by Messrs. Hornsby & Sons, the Crystal Palace District Electric Supply Co. (Ltd.) and the Engine, Boiler and Employers' Liability Insurance Co. (Ltd.) and in reply to Mr. Howard Smith, he said that they would amount to about £230.

No order as to costs was made against Messrs. Richard Hornsby & Sons, but the Crystal Palace District Electric Supply Co. were ordered to pay £150, and the Engine, Boiler and Employers' Liability Insurance Co. were ordered to pay £50 towards the costs and expenses of the investigation.

* See *The Electrician*, Aug. 10, 1900, page 590.

LEGAL INTELLIGENCE.

Taff Vale Railway Co. v. Amalgamated Society of Railway Servants and Others.

Mr. Justice Farwell on Tuesday gave his reserved judgment in the motion for an injunction against the defendant society and their officers, Richard Bell and James Holmes, from watching or besetting, or causing to be watched or beset, the Great Western Railway station at Cardiff or the works of the plaintiffs or any of them, or the approaches thereto, or the places of residence, or any place where they may happen to be, of any workmen employed by or proposing to work for the plaintiff company for the purpose of persuading or otherwise preventing persons from working for plaintiffs, or for any purpose except merely to obtain or communicate information, and from procuring any persons who may have or may enter into contracts with the plaintiffs to commit a breach of such contracts. An interim injunction was granted last week against the defendants Bell (general secretary) and Holmes (organising secretary), it being submitted, however, that the defendant society was not a real person, nor a corporate person. It was pleaded that by the Trade Union Act, 1871, the Legislature for some purposes recognised trade unions, but did not recognise them or give them an entity except for particular purposes defined in that act. For the plaintiffs it was urged that under the 1871 Act a trade union can be proceeded against for penalties. The society had asked by summons that their name be removed from the motion as defendants, on the ground that they were not proper parties to the action.

Mr. Justice FARWELL said the defendant society pleaded that they were neither a corporation nor an individual and therefore could not be sued in a quasi-corporate or any other capacity. It was undoubtedly true that a trade union was neither a corporation nor an individual, nor a partnership between a number of individuals; but this did not conclude the case. A trade union was an association of men which almost invariably owed its legal validity to the Trade Union Acts, 1871-1876. The question he had to consider was what, according to the true construction of the Trade Union Acts, had the Legislature enabled trade unions to do, and what, if any, liability did a trade union incur for wrongs done to others in the exercise of its authorised powers. The Legislature in giving a trade union the capacity to own properly and the capacity to act by agents had, without incorporating it, given it two of the essential qualities of a corporation, essential in respect of liability for tort, for a corporation could only act by its agents and could only be made to pay by means of its property. The principle on which corporations had been held liable in respect of wrongs committed by the servants or agents in the course of their service and for the benefit of the employer, was as applicable to the case of a trade union as to that of a corporation. If the contention of the defendant society were well founded, the Legislature has authorised the creation of numerous bodies of men capable of owning great wealth and of acting by agents with absolutely no responsibility for the wrongs that they may do to other persons by the use of that wealth and the employment of those agents. They would be at liberty, for instance, to disseminate libels broadcast, or to hire men to reproduce the rattening methods that disgraced Sheffield 30 years ago, and their victims would have nothing to look to for damages but the pockets of the individuals, usually men of small means, who acted as their agents. It would require very clear and express words of enactment to induce him (the learned judge) to hold that the Legislature had in fact legalised the existence of such irresponsible bodies with such wide capacity for evil, nor did he see any reason for saying that the society could not be sued in tort in their registered name. Secs. 8 and 9 of the Act of 1871 expressly provided for actions in respect of property being brought by and against the trustees, and this express intention impliedly excludes such trustees from being sued in tort. If, therefore, he was right in concluding that the society were liable in tort, the action must be against them in their registered name. The acts complained of were the acts of the association. They were acts done by their agents in the course of the management and direction of a strike; the undertaking such management and direction was one of the main objects of the defendant society, and was perfectly lawful; but the society, in undertaking such management and direction, undertook also the responsibility for the manner in which the strike was carried out. It was not a question of the rights of members of the society, but of wrong done to persons outside the society. For such wrongs, arising, as they did, from the wrongful conduct of the agents of the society in the course of managing a strike which was a lawful

Digitized by Google

object of the society, the defendant society was, in his opinion, liable. He therefore dismissed the society's summons to have their name struck out as parties to the motion, with costs. As to whether an injunction should be granted against the society in addition to that granted last week against Bell and Holmes, he was of opinion that it should. The objects of the society comprised the settlement of disputes between masters and men by arbitration, or other lawful means; the general management of the society was vested in an executive committee with power to represent the members in disputes about hours and wages; a protection fund was set apart out of the funds of the society for the more effectual protection of the labour and rights of members and for the better carrying on of any movement having that end in view, and in pursuance of its objects and powers. The society, by their letter of Aug. 20, signed by Bell, informed plaintiffs that they had decided to support the men in their action, and had instructed Bell to take charge of the movement, with a view to bringing it to a conclusion, and that all further negotiations were to be dealt with through him. Bell was the general secretary and Holmes the local organising secretary of the society. They, as agents for the society and on their instructions and for their benefit, put themselves in charge of the strike, and, on the evidence that was read before him last week, illegally watched and beset men to prevent them from working for the plaintiff company, and illegally induced men to break their contracts. He had already held that the society were liable for the acts of their agents to the same extent as they would be if they were a corporation, and it was abundantly clear that a corporation under the circumstances of this case would be liable. It was not a question of acting ultra vires, but of improper acts in carrying out one of the lawful purposes of the defendant society. In such cases the principal, whether an individual or a corporation, or an unincorporated body was answerable for every such wrong of the servant or agent as was committed in the course of the service and for the master's benefit though no express command or privity of the master be proved. Granted that the principal had not authorised the particular act, but he had put the agent in his place to do that class of acts, and he was answerable for the manner in which the agent has conducted himself in doing the business with which the principal had entrusted him.

An injunction was therefore granted against the defendant society in the terms of the order of the Court last week against the defendants Bell and Holmes (see *The Electrician* for August 31, p. 717).

MUNICIPAL, FOREIGN & GENERAL NOTES.

Aberdeen.—The accounts of the electricity department for the year ended July 31 have been issued. The total revenue was £14,211. 3s. 10d., and the expenditure £6,062. 0s. 10d., leaving £8,149. 3s. to be carried to net revenue account. From this £2,343. 15s. 11d. was paid as interest on mortgages and other loans, £2,438. 15s. 4d. for depreciation, £1,336 to sinking fund, and £2,487. 18s. 11d. to reserve, which now stands at £2,609. 17s. During the year 1,005,505 units were sold, against 279,950 for seven months in 1899. There are 76 public arc and 80 incandescent lamps. The amount of capital authorised to be borrowed is £82,000, and the amount actually borrowed is £81,953.

African Telegraphs.—It is announced that the African overland telegraph system is complete from the Indian Ocean to the sources of the Nile, and that messages from Lake Victoria are now brought by steamer to Zanzibar over a distance which formerly occupied seven months.

Bangor.—Hitherto the demand for electric current has exceeded the most sanguine expectations, and already the electricity department has orders for the equivalent of 1,000 8 c.p. lamps more than it was originally calculated would be required in three years. The works have not yet been started, but it is likely that current will be available in two or three weeks. The question of extensions has already become pressing, and a third unit of plant will shortly be ordered. The proposal to engage in municipal electricity supply encountered long and determined opposition from the gas interest, which was strongly represented on the Bangor Council, and the success already achieved is locally considered the more gratifying on that account.

Batley.—The electric lighting estimates are to be increased by £2,000.

Birkenhead.—The Gas, Water and Electricity committee are to consider the question of reducing the price of electric current to 4d. per unit. The subject was introduced by Mr. Dodds at the Council meeting on Wednesday when he said that, although they had the monopoly of electric lighting, with the exception of a favoured few the public were debarred from utilising the light. There were in Birkenhead 248 electricity meters, against 15,600 gas meters, showing that the needs of the general public were not met by the committee, and as there was no other competitor, the public had to suffer. The time had surely come when the Gas, Water, and Electrical committee should be split up, and a committee appointed which would see that the public needs in respect to electric current were met at a reasonable price.

Blackpool.—Owing to the non-delivery of machinery which has been on order for several months, the traction plant at the generating station has been overloaded for some time, and there was a breakdown in connection with the electrical tramway system on Tuesday. The present machinery is only intended to generate sufficient current to operate 18 cars, but since the Claremont-park extension was opened it has been called upon to provide motive power for 25, the result being that on Tuesday night one of the 100 H.P. turbo-generators broke down, and the tramway traffic on the Promenade was disorganised. As quickly as possible the engineer (Mr. R. C. Quin) made arrangements with Mr. J. Cameron, manager of the Blackpool and Fleetwood Tramroad Co., for an emergency supply. The company had fortunately some reserve plant which they were able to place at Mr. Quin's disposal, and it was arranged that the whole of the electricity required on the Promenade line from the Gynn to the Central Pier should be supplied from the company's works, while the other 100 H.P. turbo-generator at the Corporation works would provide for the supply from the Central Pier southwards. The electric lighting plant is also, it is stated, running at its top load just now. Considerable extensions are to be made during the winter.

Brighton.—At the Corporation meeting yesterday (Thursday) that body had under discussion a report from the Tramways committee recommending that tenders be invited for the supply of tramcars in connection with the proposed electric tramway scheme. At the outset it is proposed to invite tenders for only 30 double-decked cars, similar to those at present in use at Liverpool and Sheffield. The estimated cost of each car complete has been put at £750. The report and its recommendations were adopted by the Council.

Carnarvonshire.—The Gwyrfai District Council and the Llanrug and Llanberis Parish Councils have decided to support Mr. E. W. J. Paterson's scheme for the construction of a light (electric) railway from Carnarvon to Dinas Dinlle. It is also proposed to supply electric current for lighting in the various districts.

Cheltenham.—There is at present the equivalent of 24,970 8 c.p. lamps connected to the mains. Extensions, estimated to cost about £6,000, are to be made, and sanction to borrow this sum has been applied for.

Devonport.—The Council have adopted the electric lighting scheme referred to in our last issue, and in addition six arc lamps are to be erected in the Albert-row, at an estimated additional cost of £100.

Dungannon (Ireland).—A provisional electric lighting order is to be obtained by the Council.

"Engineering Magazine."—The September issue contains articles on "Electric Mining Machinery in the British Collieries," "The Continuous Recording of Steam Engine Practice," "Commercial Organisation of the Machine Shop," "Commercial Requirements of Water Power Governing," and "Heavy Motor vehicles for Road Service."

Fire.—Owing to the overheating of a cable at the Bank station on the City and South London Railway early on Thursday morning a small fire occurred, which was speedily overcome by the Fire Brigade. Had the fire originated at a busy time of the day the only inconvenience that would have resulted would have been the temporary putting out of use of one of the lifts at this station. No interruption with the regular working of the line would have occurred.

Hawthorn (Victoria).—After various discussions on electric lighting matters the Municipal Council has resolved to transfer its electric lighting order to the Electric Lighting and Traction Co. of Australia for £150.

Ithaca (Queensland).—The streets are to be lighted electrically, current being obtained from the Brisbane Tramways Co.

Leeds.—Electricity meter rentals are to be abolished from Oct. 1. The Corporation resolved, on Wednesday, to promote a bill to authorise the construction of six additional tramway routes.

Leith.—The Burgh Electrical Engineer (Mr. J. Gray Scott) has reported that the cost of a new feeder to Newhaven-road would be £5,375. Interest and sinking fund would amount to £429, and the probable revenue would be £440 per annum. On account of the increasing demand for current a new feeder to Bernard-street was also absolutely necessary. This would cost £1,217, and Mr. Scott strongly recommended the work be carried out without further delay. The capital expenditure on electric lighting to date is £43,011. 1s. 8d., and in order to carry out further extensions it will be necessary to obtain further permission from the Secretary for Scotland to borrow. The entire question was remitted, on Tuesday, to the Executive sub-committee for report.

Light Railways.—The Light Railway Commissioners will hold an inquiry on 17th inst. into the application to construct the Kidderminster and Bewdley light (electric) railway.

An inquiry will be held at Wigan on 26th inst. by the Light Railway Commissioners into the application to construct a light electric railway in the district.

The Elland District Council have approved the proposal to construct a light railway in the Deanhead Valley, Yorks.

Digitized by Google

Liverpool.—The Seaforth, Waterloo, Crosby and Blundell Sands electric tramway was opened on Saturday. The new line, between 2 miles and 3 miles in length, has been constructed by the Liverpool Overhead Railway Co., and is intended to form a continuation of their electric railway from Dingle to Seaforth.

Long Eaton.—The Council, who are considering the question of erecting gas-driven electricity works, have sent a deputation to Northwich to inspect the Mond system of gas production.

Market Harborough.—The Gas committee is investigating the desirability of obtaining electric lighting powers and has been authorised to engage an electrical expert to prepare a report.

Mexborough.—The Council, who are advertising for electricity generating plant, propose to light the leading thoroughfares electrically. Application has been made to the Local Government Board for sanction to a loan.

Municipal Telephony.—At the meeting of the Grantham Council on Wednesday the Telephone committee reported that they considered a municipal telephone system could be successfully worked, and promised to lay detailed estimates before the Council at its next meeting.

Merchant Venturers' Technical College Calendar.—The calendar of this college for the Session 1900-1901 is now published, and gives full particulars of the course of technical instruction. An excellent set of photographic illustrations of the engineering and physical laboratories and workshops, dynamo and testing rooms are included. Day and evening classes in all branches of electrical and mechanical engineering, telegraphy and telephony form a conspicuous feature of the syllabus.

Northampton Institute Calendar.—The calendar of the educational and social announcements of this Institute for the Session 1900-1901 is just issued, and contains full particulars of the tuition given in (1) engineering and metal trades, (2) artistic crafts, (3) electrical engineering and applied physics, and (4) technical chemistry, in addition to special instruction in the trades with which the district of Clerkenwell is intimately associated. The Institute is well endowed with laboratories and workshops, and illustrations of these are given in the calendar. On pp. 10 to 31 particulars are published of the chief new feature for this Session—the engineering day courses, to which the special attention of students is called.

Paisley.—At a recent meeting of ratepayers it was resolved to invite the promoters of the Glasgow and District tramway scheme, which was rejected in the last session of Parliament, to again promote a bill.

Paris Exhibition—Messrs. Boot and Son, of 24, Old Bailey, London, E.C., announce that the demand for the "Anglo-Saxon Guide" to the Paris Exhibition has necessitated a second edition. A copy of the new edition has been forwarded to us, and includes a list of the British awards. It is difficult to see how a visitor to Paris for the exhibition can do without this guide, and even those who are compelled to stay at home may spend a shilling much more wastefully than in purchasing a copy of the "Anglo-Saxon Guide to the 1900 Paris Exhibition."

Peterborough.—£8,118. 3s. 7d. has already been expended in connection with the electricity supply scheme, and the amount incurred in contracts and not yet paid is £8,450. 0s. 10d., making a total of £16,568. 4s. 5d. The engineer (Mr. J. C. Gill) estimates that £2,056. 16s. is necessary to complete the equipment of the works. There is a net excess expenditure to date of £2,660, but this is partly accounted for by the change of site for the generating station.

Penang (Straits Settlements).—The municipality have considered and adopted a scheme for the electric lighting of the town which has been prepared by Mr. O. V. Thomas. In the course of the discussion on the scheme, Mr. Bromhead Matthews said the town was at present inadequately lighted by 746 9 c.p. oil lamps, which each cost $2 per month. Including maintenance the total cost was $17,904 a year, and the increase in the price of oil made it impossible to renew the contract except at from 40 per cent. to 50 per cent. above the present rate. In his scheme Mr. Thomas proposes to light the public streets, roads, markets, quays, &c., by 40 arcs of 2,000 c.p. each, and 950 16 c.p. incandescents. The latter will be placed 50yds. apart, and the arcs 100yds. The estimated capital cost of the public lighting is put at $160,000, and the maintenance at $29,000 per annum. The generating plant will cost about $280,000. It is intended to make provision for supplying current to the equivalent of 7,500 8 c.p. lamps for private houses. The annual cost of maintenance of the entire project would be about $60,800, or $30,800 more than is being paid for oil. The scheme was adopted unanimously.

Ripon.—The Council have resolved to apply for a provisional electric lighting order, and Messrs. G. Harrison & Co. have been appointed consulting engineers.

St. Pancras (London).—At the Vestry meeting on Wednesday the chairman of the Electricity committee (Dr. W. Smith) presented a report setting out the net profit on the electricity undertaking since its inauguration in 1892. This profit amounted to £18,288, and admitted of a contribution in relief of rates of £3,000, a reserve fund of £12,000, and the carrying forward of £1,134. Dr. Smith explained that the Vestry would hand over to its successors, the new borough council, property worth £300,000, which had not, and would not cost the ratepayers a penny. Had their undertaking been a joint-stock concern, it would have paid a dividend at the rate of 6 per cent.

Saltburn.—The Cleveland and South Durham Assets Co. offer to sell their electricity supply undertaking to the District Council for £10,000.

Sheffield.—Ever since the appointment of Mr. S. E. Fedden to the important post of general manager of the electric light department at Sheffield that gentleman has been exercised as to the best means of dealing with the problem of adequately providing for the rapidly-increasing demand for electric current, more especially for motor driving. Mr. Fedden has presented a report (dated 24th August) to the Electric Light committee of the Corporation to guide them in purchasing additional generating plant. Mr. Fedden says:—

For some years it has been conclusively proved that the business of electricity supply, if properly managed, is one of the most profitable upon which a municipality can embark, and one in which a bold and liberal policy is not only the safest, but also the cheapest in the end. It is remarkable how enormous the demand for electric light and power has been when an efficient supply of energy has been available at a moderate cost, even though it may be somewhat dearer than gas. In consequence of this large demand (not yet felt by Sheffield) many electric supply works have required extensions in a very short time, on account of their having been originally laid out on too small a scale. The site chosen has in many instances been most unsuitable, or it has been impossible to extend the buildings, and therefore extensions have taken the form of entirely new works designed with more consideration for the district's requirements. By alterations such as these the waste of a large amount of capital is involved and the future cost of production thereby increased. In Sheffield very large provision must be made for the future, because not only are the suburbs extending rapidly (and these suburbs should be electrically lighted), but the central portion of the city, with its workshops and small power users, may be expected to make an unprecedented demand on the electric supply department as soon as you are able to supply electric energy suitable for power, heating, &c., at a reasonable charge (say, 1½d. to 1d. per unit). You are doubtless aware that in the present session of Parliament several very large power schemes have been sanctioned, and that intimation of intention to apply for one for this district has been received. If, therefore, Sheffield desires to preserve its monopoly of supply it can only be by looking forward to the future, and so designing the works as to cope with any demands that may be made. The cost of mains is, no doubt, considerable, but the advantage of a large and well-covered area of supply cannot be over-estimated, for it must not be forgotten that the applications of electricity will become increasingly varied. An electricity works is not laid down for the supply of light only, but also for the supply of power, which, in Sheffield, will almost certainly form a large proportion of your future demand.

In dealing with the future supply of the district one is hampered by what has already been done. If I had to design a completely new system for Sheffield I should, for numerous technical reasons, certainly propose to distribute on the continuous-current system in the central area, although I should generate and transmit my electrical energy from one large power station by polyphase alternating currents to different points in the city, and there transform it into continuous currents by means of rotary converters. You have, however, an extensive alternating system already laid down, for which a very large sum of money has been paid, and without further heavy expenditure the introduction of the system just described is impossible. I am glad, however, to be able to report that, with certain modifications, your existing system can be brought up to date, and this being so, I certainly do not feel justified in making so radical a change as that to continuous current supply, which would involve a very heavy, and, in the circumstances, unnecessary expenditure.

In considering the question of the best means of dealing with the future supply of the city, I have naturally carefully perused the reports that were last year laid before you by my predecessor, and by Mr. Robert Hammond. I specially bear in mind the five conclusions appended to Mr. Hammond's report of Oct. 31, 1899. With these conclusions I am in accord, except No. 3 as follows:—

(3) That the direction in which future economies can be effected is in the cessation of expenditure on further alternating plant, and the feeding of the central district by low-pressure continuous current.

With regard to this suggestion (3), I am convinced that the economies which were in view can be better effected by other means. I may remark, in passing, that I cannot help thinking that at the time Mr. Hammond made his report he had not the full data laid before him as to the method of feeding and distributing the electricity in the central area. Since I have been in charge of the undertaking I have, of course, made myself thoroughly acquainted with these matters, and I am glad to be able to say that I find the loss due to the magnetising watts of transformers, referred to by Mr. Hammond as an incubus on the undertaking, can be very considerably reduced by a change in the system of feeding. In support of the modification of the existing system rather than change to a new one, I may mention that the continuous-current low-pressure feeders alone to deal with the central area would cost not less than £30,000, the interest and sinking fund on which would far outweigh the economies which would ensue, from the avoidance of loss due to the magnetising watts above mentioned. The system of sub-stations hardly exists in Sheffield, but as you are aware, I am already inaugurating it, and suggest that the system should be gradually intro-

Digitized by Google

duced, the result being that our magnetising watts, or in other words, wasted current, will be largely minimised.

I, therefore, conclude that the development of the undertaking, as far as principle is concerned, must be on the lines of extending the system already in existence, modified as indicated below. To make the system more suitable for motive power, I strongly recommend the reduction of the periodicities from 100 to 50. In connection with this recommendation I may point to Frankfort as a city where the single-phase alternating current, being the same as the Sheffield system, is in use. The motors upon the circuit amount to as much as 5,000 H.P., 2,800 H P. of which is distributed throughout the city to users in various small industries, the balance (2,200 H.P.) being applied in the form of motor generators for driving the tramways which belong to the municipality. Similar conditions, though in a smaller degree, also obtain at Derby, Huddersfield, Leeds, and numerous other towns in this country. Another advantage of changing our present plant from 100 periods to 50 periods would be that the plant would then be suitable for running in parallel with the large power station which Sheffield must shortly possess. I may add that the quality of the lighting would not be prejudicially affected by the change.

If you sanction the suggested change from 100 periods to 50 periods, the sets of plant would have to be changed one by one, as opportunity occurred, and, of course, during the change each particular set would be unavailable for service on the load. To enable the alteration being carried it will be necessary to order two sets of plant (alternating 50 period), say each of 100kw., to be delivered, if possible, before March, 1901, and when these are installed to gradually transform the present sets set by set. The cost of altering the present system to 50 periods will be about £9,400 (this includes alternators, motors, meters, and arc lamps). To carry out the above recommendations I estimate the following further expenditure for 1901 :—

Additions and alterations in boiler house	£3,500
200kw, of new plant complete.....	22,000
Additional feeders	5,000
Contingencies, say 5 per cent.....	1,995

This, if carried out, will completely fill up your present station, and the position will then be that your existing space will be all occupied and the machinery therein put on a footing to give the best possible results as a system. It will further have been put into a position to fit in and harmonise with the station to be designed and constructed on more extensive lines. As to this larger station, it should, in my opinion, be taken in hand without delay, so that it may be steadily proceeded with concurrently with the recommendations above made. I have already instituted inquiries as to a suitable site, and am now engaged in maturing the details of the subject and preparing estimate of cost, with a view of presenting to you a full report at an early date.

This report has been fully discussed by the Electric Light committee, and has been referred to Mr. R. Hammond for his views. In connection with this matter, a deputation consisting of Ald. Styring, Mr. W. W. Harrison (or, failing him, Mr. John Maxfield) and Mr. Fedden are visiting the Paris Exhibition in order to inspect and examine the latest machinery there on view. The deputation may possibly go to Frankfort to inspect the Brown-Boveri single-phase plant there installed.

Stalybridge.—The Council have approved the joint electric lighting and tramway scheme for Stalybridge, Hyde, Mossley, and Dukinfield, and the Mayor (Ald. Simpson), and Alds. Fentem, Norman and Ridyard, and Messrs. Thompson and Wood, have been appointed Stalybridge representatives, with full power to take all proceedings for promoting the necessary bill. On Tuesday the Mayor said the proposed scheme would entail an expenditure of something like £400,000, and the proposed tramways would cover an area of about 26 miles.

Standish (Lancs.).—A provisional electric lighting order is to be obtained by the District Council.

Tramway Provisional Orders in 1900.—The Board of Trade have issued a report on the manner in which the applications for tramway provisional orders were dealt with last session. The number of applications was 36, the largest since 1881, and 35 of these included power to construct new or extend existing tramways, the remaining one (that of the British Electric Traction Co. for Rothesay) was for authority to employ mechanical power on existing lines. Twenty-seven of the applications were by local authorities. The aggregate length of the proposed tramways was 59 miles 4 chains of double line and 99 miles 49 chains of single line, and the cost of construction was £1,626,307. Four applications were not proceeded with—viz. : Ealing (Council), Hemel Hempstead (British Electric Traction Co.), Surbiton (Council) and Walthamstow (Council). The first was withdrawn, the second refused in the absence of consent of the local authority, and the other two were rejected on account of non-compliance with the terms of the Tramways Act, 1870 ; 32 provisional orders were granted, and although considerable opposition was offered to the confirmation of some of the orders by Parliament, all the confirmatory bills were passed and received the Royal assent on Aug. 6. The list of the orders confirmed is identical with that which appeared in our issue of Jan. 5 last, with the exception of Ealing, Hemel Hempstead and Walthamstow, which should be omitted.

Tunbridge Wells.—As will be seen from the list of tenders accepted, set out in another column, the Council have definitely committed themselves to a municipal telephone scheme. Tunbridge Wells thus becomes the second local authority in the kingdom to embark upon municipal telephone enterprise, Glasgow having the honour of premier place. The Council anticipate being able to provide a system which will cost subscribers less by £2. 10s. than they are now paying the National Company. To meet the threatened competition the company has lately been advertising reduced rates, but still the Corporation maintain they can provide a better and cheaper service without trenching upon the borough rates to any extent. As the result of a canvass upwards of 300 subscribers have already been obtained, the majority of whom are at present customers of the National Company. The scheme also provides for a service to the surrounding villages, where the proposal has, it is said, already been regarded with approval. It is estimated that the initial cost of the installation will be £9,000, and the annual cost of working about £1,000.

Warrington.—The charge for electric current for motive power has been fixed at 2d. per unit for the first 3,000 units per quarter and 2d. after.

Worcester.—The charge for electric current to private consumers has been increased from 6d. per unit for the first two hours' maximum demand and 2½d. after to 6½d. and 3d. respectively. For waterworks motors, the charge will be 1¾d. per unit ; for the public arc lamps, an additional £2. 2s. for each all-night lamp, and £1. 1s. for a half-night lamp, and for the public incandescent lamps 5s. each per annum will be charged.

Workhouse Lighting.—Bradford Workhouse is to be lighted electrically, and the Local Government Board have sanctioned a loan of £6,500 for the work, to be repaid within 10 years.

Worthing.—The Council have received a number of tenders for the supply of electricity generating plant, and on Monday these were referred to the consulting engineers (Messrs. Burstall and Monkhouse) for analysis and report.

Wrexham.—The Council are making progress with their electric lighting scheme, and it has been decided to charge 6d. per unit for current for lighting and 3d. for power.

The undertaking of the Wrexham Tramways Co. has been acquired by the Drake and Gorham Electric Power and Traction Co., and the lines are being converted to electric traction.

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers, or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London :—

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free. The author treats fully both the theoretical principles of the art of electrolytic separation of metals and the practical rules and details of technical application on a commercial scale. The work is adapted to the use of the manufacturer as well as the student.

"ELECTROMAGNETIC THEORY."—By Oliver Heaviside. *Vol. I.*, 12s. 6d. *Vol. II.*, 12s. 6d.

"DRUM ARMATURES AND COMMUTATORS," by Mr. F. Marten Weymouth. also ready. Price 7s. 6d., post free. Prospectus on application. This is a complete treatise on the theory and construction of drum winding, and of commutators for closed coil-armatures, together with a *résumé* of the principal points involved in their design, and an exposition of armature reactions and sparking.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket book, by Messrs. W. Geipel and H. M. Kilgour; price 7s. 6d. ; by post, 7s. 9d. ; abroad, 8s. *New Edition nearly ready.*

"BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH."—A valuable compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of general as well as special information bearing upon the whole subject of electrical discharge research. Edited by C. E. S. Phillips. Price 5s., post free.

"THE MANUFACTURE OF ELECTRIC LIGHT CARBONS."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated, price 1s 6d. ; post free, 1s. 9d. In this work the author gives useful hints as to the manufacture of electric light carbons, including the preparation of material, firing, saturating, and coring, together with a description and estimate of cost of the plant required.

"THE ELECTRICIAN" READING CASE.—To hold four numbers of the journal. Strongly bound, 1s. net; post free, 1s. 4d.

"LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS."—By F. C. Raphael. Price 5s., post free. The book deals with the important subject of localising faults in electric light and power cables; and the various methods of insulation testing are here collected and discussed.

"WIRELESS TELEGRAPHY : SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES." A Review of the Work of Hertz and his Successors.—By Dr. O. J. Lodge, with a large number of illustrations, bringing this latest application of electrical science quite up to date. New and Enlarged Edition, 5s. nett. *Now ready.*

"THE CENTENARY OF THE ELECTRIC CURRENT, 1799-1899."—By Dr. J. A. Fleming. Price, paper covers, 1s. net, post free 1s. 3d.; strong cloth, s. 6d., post free.

"THE MANUFACTURE OF CARBONS FOR ALL ELECTRICAL PURPOSES."—by Francis Jehl. 10s. 6d., post free. This is a practical handbook, giving a complete description of the art of making carbons for electric lighting, electrodes, &c., with particulars of the various gas generators and furnaces used in carbonising. The work also contains particulars of the cost, &c. of erecting and working carbon works, and plans of a model factory.

Digitized by Google

"MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY."—By E. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free. In this comprehensive work an account is given of the scientific principles and modern practice in the use of engines for dynamo driving, not only for isolated power plants, but also for public electric lighting and power stations. The various forms of gearing in the power station and for electric motors are also dealt with; and the book contains, in addition, numerous tables giving exact data of the equipment and working of electric power stations.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. *New and Cheaper Edition*, 6s., post free.

"THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING."—A new edition of this book, by Messrs. H. K. C. Fisher and J. C. H. Darby, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated.

"ELECTRO-CHEMISTRY."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—By Gilbert S. Ram. Price 7s. 6d., post free. The principles underlying the manufacture of the incandescent lamp are carefully and fully dealt with in this volume.

"MAGNETIC INDUCTION IN IRON AND OTHER METALS."—By Prof. J. A. Ewing. Price 10s. 6d. net. *New Edition (Third) now ready.*

"ELECTRIC MOTIVE POWER," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. Price 10s. 6d., post free; abroad, 11s.

"ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. Demy 8vo, fully illustrated. 10s. 6d., post free.

"SUBMARINE CABLE-LAYING AND REPAIRING."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d. This work gives a detailed technical summary of modern practice in manufacturing, laying, testing, and repairing submarine telegraph cables.

"THE ALTERNATE CURRENT TRANSFORMER."—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. Vol. I.—*New Edition.* Price 12s. 6d., post free, Vol. II., price 12s. 6d., post free, is also ready.

"ARMATURE WINDING OF ELECTRIC MACHINES."—By H. F. Parshall and H. M. Hobart. This work has been compiled from notes made by Mr. Parshall in his capacity as Chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables, 30s. post free.

"LABORATORY NOTES AND FORMS."—We have ready a set of 40 Elementary and Advanced Exercises for use with Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of the series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net; in sets of any three, 1s. net; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net; or in handy portfolio, price 12s. net; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnics and other Science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper, and with less space for tabulated records, are issued at half the price of the original set.

"THE POTENTIOMETER AND ITS ADJUNCTS": A Universal System of Electrical Measurement.—By W. C. Fisher. Fully illustrated. Price 6s., post free.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office no later than first post Thursday morning. New Catalogues, Price Lists and similar matter should be sent early in the week.*]

TENDERS INVITED.

Walthamstow District Council invite tenders for the supply and erection of electric lighting plant and apparatus, including gas plant, gas engines, dynamos, switchboard, boosters, balancer and measuring instruments. Specifications may be obtained from the consulting engineer (Mr. James Enright), 47, Victoria-street, London, S.W., after Sept. 4. Further particulars are given in an advertisement, and tenders must be delivered to the town clerk (Mr. E. J. Gowen), Town Hall, Walthamstow, by 5 p.m., Sept. 25.

Sunderland Corporation invite tenders for triple expansion high-speed direct-current steam dynamos, Lancashire boilers, and feed pumps. Specifications may be obtained from the borough electrical engineer (Mr. J. F. C. Snell), Dunning-street, Sunderland, and tenders (addressed to the chairman of the Electric Lighting committee) must be sent to the town clerk (Mr. Francis M. Bowey) by noon of Sept. 21. An advertisement gives further particulars.

Dublin Electric Lighting committee invite tenders for the supply and laying of electricity supply mains and accessories. Specification may be inspected at the office of the city engineer (Mr. Spencer Harty), City Hall, Dublin, and may be seen at and obtained from the offices of the consulting engineer (Mr. Robert Hammond, 64, Victoria-street, London, S.W.), after Sept. 3. Further particulars are given in an advertisement, and tenders, addressed to the town clerk (Mr. Henry Campbell), City Hall, Dublin, must be in by 4 p.m. of Oct. 4.

Dublin Corporation also invite tenders for supply and erection of power machinery at Ringsend, including pumping engines and pumps, boilers, electric motors and pumps. Specification, &c., may be obtained from the city engineer (Mr. Spencer Harty), or from the consulting engineer (Mr. G. Chatterton), 6, Sanctuary, Westminster, London, S.W. Further particulars are given in an advertisement, and tenders must be sent to the town clerk (Mr. Henry Campbell), City Hall, Dublin, by noon, Oct. 3.

Dundalk District Council invite offers for the transfer of their provisional electric lighting order. Some particulars are set out in an advertisement, and any further information can be obtained at the office of the borough surveyor. Tenders to the town clerk (Mr. Mathew Comerford), Town Hall, Dundalk, before 1 p.m. Sept. 18.

Mexborough District Council invite tenders for electricity generating plant, particulars of which are set out in an advertisement. Copies of the specification, &c., can be obtained from the electrical engineer to the Council (Mr. H. Waring), 18, Berkeley-road, Crouch End, London, N., and tenders must be delivered to the clerk (Mr. J. W. Hattersley), Mexborough, before Sept. 15.

Manchester Tramways committee invite tenders for two steel boilers, cast-iron pipes, rubber rings, bolts and nuts, steel stanchions, &c., and 100 car trucks. An advertisement gives further particulars, and specifications may be obtained from the general manager, Tramways Department (Mr. J. M. M'Elroy). Tenders (addressed Chairman of Committee), to the town clerk (Mr. W. H. Talbot), by 18th inst.

Eastbourne Corporation invite tenders for the supply and erection of water-tube boilers, with fittings, feed pumps, &c.; 400kw. steam alternator, with exciter (vertical enclosed high-speed engine); and main switchboard and connections. Further particulars are given in an advertisement, and specification may be obtained at the offices of the town clerk (Mr. H. West Fovargue), Town Hall, Eastbourne. The works are to be carried out to the plans and specification of the consulting engineer (Mr. W. C. C. Hawtayne), 9, Queen-street-place, London, E.C., from whom further information may be obtained. Tenders to the town clerk before noon Oct. 4.

The Vestry of St. John, *Hampstead* (London) invite tenders for eight dry-back marine boilers, steam and water pipes, feed pumps, &c., feed-water heater (or feed-water detartariser), fuel economiser, cast-iron water tank, and two blow-off tanks. Tenders to vestry clerk, Vestry Hall, Hampstead, N.W., by 4 p.m., Sept. 27.

Salford Corporation invite tenders for twelve months' supply of high and low-tension single and concentric cables, house fuse boxes, meters and meter boards. Tenders to town clerk before Sept. 10.

Oldham Electric Light committee invite tenders for dry-back marine boilers, with mountings, gangways, feed and drain pipes, &c., complete, and also for mechanical stokers with shafting and gearing for driving; or water-tube boilers as an alternative to the dry-back marine boilers, including mountings, &c. Tenders to superintendent (Mr. A. Andrew), Gas and Water Office, before Sept. 11.

London County Council invite tenders for mains for the electric lighting of Victoria Embankment and Westminster Bridge. Tenders to clerk (Mr. C. J. Stewart) before noon Sept. 24.

London County Council Asylums committee invite tenders for boilers, engines, dynamos, &c., at Horton Estate, Epsom, Surrey. Tenders to committee, 6, Waterloo-place, S.W., by 10 a.m. of Sept. 22.

Aberdeen Electric Lighting committee invite tenders for two 200kw. direct-coupled continuous-current generators and one 120kw. balancing set; also for one 420kw. direct-coupled continuous generator. Willans engines are specified in both cases. Tenders to city electrical engineer by Sept. 29.

Hackney (London) Electric Lighting committee invite tenders for condensing plant, cooling apparatus, pipework and valves, feed pumps, switchboard and boosters, arc lamps, meters, crane, and workshop equipment. Tenders to vestry clerk by 4 p.m., Sept. 12.

Hammersmith (London) Vestry require tenders for the supply, delivery and erection of two single-phase alternate-current motors, coupled to two centrifugal pumps, with accessories. Tenders to clerk before 5 p.m., Sept. 12.

The managers of the *Poplar* and *Stepney* Sick Asylum District invite tenders for sundry work in connection with a telephonic installation at their sick asylum. Tender to clerk, Bromley, Middlesex, by 5 p.m., Sept. 17.

Digitized by Google

Hull Electric Lighting committee invite tenders for steam and water pipes, feed-pumps, water-softener, &c., for their Sculcoates-lane generating station. Tenders (addressed chairman of committee) to town clerk's office by noon, Sept. 27.

British Electric Traction Co. invite tenders for constructing about 7 miles of light railway in Middleton and Castleton. Tenders to secretary, Donington House, Norfolk-street, London, W.C., by 15th inst.

Tenders are invited for the electric lighting of the new drill hall, *Portsmouth*. Tenders must be sent to the Col.-Commandant (A. R. Holbrook), Drill Hall, Alfred-road, Portsmouth, by 5 p.m. Sept. 10.

Blackpool Tramway committee require tenders for constructing tramways equivalent to 5 miles single track. Tenders to chairman of committee by 17th inst.

Perth Commissioners require tenders for direct-current electricity meters and cutouts. Tenders to clerk by 15th inst.

Glasgow Corporation invite tenders for the power station piping required at Pinkston. Tenders to town clerk by 5 p.m. Sept. 28.

Tunbridge Wells Corporation invite tenders for high and low-tension cables. Tenders to town clerk by Sept. 29.

Nelson Corporation invite tenders for a 200kw. steam dynamo. Tenders to town clerk by Sept. 8.

Southampton Harbour Board invite tenders for a 30-cwt. portable electric wharf crane. Tenders by Sept 17.

Luton Town Council require tenders for watt and demand meters. Tenders to town clerk by Sept. 14.

The Government of *South Australia* invites tenders for 400 miles of galvanised wire netting (200 miles 36in. wide, 1½in. mesh, 18 S.W.G.; and 200 miles 42in. wide, 1½in. mesh, 18 S.W.G, delivered in lots of not less than 100 miles of each size and in rolls of 100 yards each). Forms of tender, conditions, and all further information can be obtained at the office of the Agent-General for South Australia, 1, Crosby-square, London, E.C.

TENDERS RECEIVED AND ACCEPTED.

Hanley Town Council have received the following tenders for boiler house requirements for their electricity supply works :—

Two Lancashire Boilers.

E. Danks & Co. (*accepted*)	£1,660 0	Tinkers Limited	£2,010 0
Wm. Arnott & Co.	2,260 0	J. and J. Horsfield	1,935 0
R. Taylor & Sons	2,029 0	W. R. Renshaw & Co.	1,895 0

Water Tank and Pumps.

T. Shore & Sons (*accepted*)	£323 0	Edwin Danks & Co.	£387 10
Davie and Horne	585 0	Geo. Fletcher & Co.	386 0
Hunt Brothers	395 0	W. R. Renshaw & Co.	384 10
Wheeler Condenser Co.	393 10	J. Whitley & Co.	374 0
Phœnix Foundry Co.	387 10		

Fuel Economiser.

	Engine.	Economiser.	Total.
E. Green & Son (*accepted*)	£25 0	£473 18	£498 18
Phœnix Foundry Co.	35 0	676 10	711 10
Edwin Danks & Co.	—	—	550 0
Clay Cross Co.	26 0	489 0	515 0
W. R. Renshaw & Co.	25 0	459 0	484 0
J. Carter & Sons	36 10	434 2	470 12
Arthur Lowcock (Ltd.)	24 0	417 12	441 12

Smoke Fans and Engines.

	Fans.	Engines.	Total.
Davidson & Co. (*accepted*)	£165 0	£164 0	£329 0
W. R. Renshaw & Co.	177 0	176 0	353 0

Feed-Water Heater.

T. Shore & Sons (*accepted*)	£219 10 0	W. R. Renshaw & Co.	£275 18 5
Davie and Horne	527 0 0	Edwards and Barnes	249 15 0
Ditto	250 0 0	Isaac Storey & Sons	210 0 0
Phœnix Foundry Co.	365 0 0	Ditto	196 0 0
Edwin Danks & Co.	327 10 0	Wheeler Condenser Co.	196 0 0
Joseph Wright & Co.	293 0 0	G. Fletcher & Co.	171 0 0

Forced-Draught Furnaces.

Wilton Furnace Co (*accepted*)	£252 10 0	W. R. Renshaw & Co.	£290 0 0
W. A. Grainger	356 0 0	Meldrum Bros.	275 0 0
Horsfall Destructor Co.	305 0 0	A. Pillatt & Co.	231 0 0

Coal Conveyor.

New Conveyor Co. (push plate) (*accepted*)	£258	Spencer & Co. (spiral)	£340
Graham and Morton (push plate)	492	E. Bennis & Co.	359
Spencer & Co.	476	S. S. Stott & Co. (spiral)	166
		Barry Henry & Co. (spiral)	145

Mechanical Stokers.

Wilton Furnace Co. (*accepted*)	£190	J. Proctor	£303
E. Bennis & Co.	480	Meldrum Bros. (stokers alone)	285
Ditto	320	Ditto (with furnaces)	560

Grease Separator.

Joseph Wright & Co. (*accepted*) £160

The building works contract has been given to Messrs. C. Cornes & Sons at £649. 10s.

On Wednesday Tunbridge Wells Town Council accepted the following tenders in connection with their proposed municipal telephone exchange :—

W. T. Henley's Telegraph Works Co. (supplying, laying, and jointing armoured telephone cable)	£2,373 10 0
General Electric Co. (telephone instruments)	843 0 0
Ditto (insulators)	216 19 8
Wade & Co. (creosoted poles)	702 2 3
Bolton & Sons (hard copper wire)	518 0 0
Ditto (soft ditto)	21 11 8
Telegraph Manufacturing Co. (switchboards)	282 15 6
Ditto (insulated wire)	218 10 0
International Electric Co. (lightning and high-tension guards)	102 1 0
Bullers Limited (miscellaneous ironwork)	92 2 2
Apsden & Co. (oak arms)	64 9 2
W. F. Dennis & Co. (iron and steel stay wire)	37 15 0
Indiarubber Co. (batteries)	35 5 0
Potter & Co. (arm-bolts, nuts and washers)	10 0 0

The contracts for fixing subscribers' instruments and for supplying erecting and staying poles, wires, arms, insulators, &c., have not yet been let.

Limerick Town Council had before them last week the report of their consulting engineer (Mr. J. Enright) on the tenders recently submitted for the supply and erection of electricity generating plant. Nine tenders were received for the plant, the figures ranging from £12,157 (Alliance Electrical Co.) to £14,050 (British Schuckert Co.). Eleven tenders were received for the cables, the lowest being from Messrs. Porte, Sykes & Co., at £4,226, and the highest from Messrs. Johnson and Phillips, at £6,349. 5s. 2d. Mr. Enright stated that he had written to Messrs. Porte, Sykes & Co. asking for an explanation of their quoting £1,000 less for Glover cables than that at which Messrs. W. T. Glover & Co. themselves offer. The report states that from the small differences in the totals of the different contractors it would be seen that the competition had been particularly keen. Two tenders for cables differed only by a few pounds. The whole of the work could be done for £16,797. 10s. if the Council wished to have three separate contractors. Messrs. Porte, Sykes & Co. offered to do the whole work for £17,000, and Messrs. Crompton & Co. for £17,498. 15s. 2d. The report is at present under consideratiion.

The following tenders have been received by the Darlington Town Council for the supply of arc lamp posts and brackets :—

Maxim Electrical and Engineering Export Co.	£1,181 5 0	J. Allan & Son	£485 12 6
W. A. Baker & Co.	767 7 6	Rowland Carr & Co.	477 15 0
F. E. Kershaw	490 0 0	J. and A. Law	428 15 0
		Mackenzie Bros.	378 17 6

Torquay Town Council have accepted the following tenders for additional plant for their electricity works :—

Babcock and Wilcox (two water-tube boilers and superheaters, without brickwork)	£1,380
Ditto (pipework, condenser, tank, &c.)	2,653
Rosling, Appleby and Fynn (one 250kw. and one 40kw. steam alternator)	3,635
S. Z. de Ferranti, Ltd. (switchboard extension)	220
General Electric Co. (meters)	60
British Electric Transformer Manufacturing Co. (four transformers)	258
S. Blatchford (foundations)	144

Fulham (London) Vestry have received the following tenders for wiring the town hall :—

Cecil Cooper & Co. (*accepted*)	£493 10	F. Troy & Co.	£695 0
W. Douglas & Sons	1,249 6	G. E. Taylor & Co.	671 10
J. Bolding & Sons	899 10	National Electric Wiring Co.	649 0
D. Hulett & Co.	750 0	Concentric and General Contract Co.	637 0
T. L. Hellyar	725 4		

The Bradford Guardians have accepted the following tenders for electric lighting plant :—

Messrs. C. A. Parsons & Co. (generating plant, &c.)	£920
Electrical Power Storage Co. (storage battery)	1,025
Mr. G. A. Steinthal (wiring, &c.)	308
G. F. Cook & Co. (building)	613

The Hart Accumulator Co., Marshgate-lane, Stratford, have obtained the contract for the supply of the storage battery required in connection with the extension of the Blackpool Corporation electric tramway system.

Accrington Corporation have accepted the tender of Messrs. Maund and Seed, of Southport, for wiring the electricity works at £245. Tenders were also submitted by the following :—National Electric Wiring Co., Thomas Barton, Simpson Bros., G. H. Woods & Co, Alliance Electrical Co., H. A. Jackson & Co.

Liverpool Tramways committee have ordered from Messrs. Dick, Kerr & Co. 100 additional electric tramcars of similar type to those at present being supplied under the existing contract, and at the price specified therein. The firm have already supplied 300 cars to the entire satisfaction of the committee.

Digitized by Google

Cardiff Electric committee recommend the acceptance of the tender of Messrs. Lace & Son for the supply and erection of steam pipes, feed-water heater, and pump for the electricity works in Eldon-road at £1,379. Six tenders, varying from £1,379 to £2,500 (by Messrs. Danks & Co.) were received. The committee have also accepted the tender of the British Insulated Wire Co. for street cables.

Newcastle-on-Tyne Corporation have accepted the tender of Messrs. Mather and Platt for pumping plant at the tramway power house at £1,470. Contracts for laying the east section of the tram lines (for £26,072) and the west section (for £24,405) have been let to Mr. E. Nuttall and Mr. J. J. Robson respectively.

Salford Electric Light committee are reported to have recommended the Corporation to place an order with Messrs. W. T. Glover & Co. for supplying and laying electric lighting cables, tramway feeders, &c., for £159,648. 12s. 8d.

Aberdeen Town Council has accepted the tender of Mr. Alexander Spark for the supply of house main fuse boxes for twelve months, that of Messrs. S. Z. de Ferranti (Ltd.) for electricity meters, and that of the British Insulated Wire Co. for cables. There were 6 tenders for the fuse boxes, 6 for the meters, and 8 for the cables.

The tender of Messrs. Wilkinson and Houghton has been accepted for the erection of a power station for the Great Grimsby Tramways Co. at £6,310, and for the erection of a depôt at £5,003.

The tender of Mr. G. L. Adamson has been accepted by the Rochdale Council for wiring the town hall.

Chelmsford Council have accepted the tender of Mr. T. H. P. Dennis for keeping the fire alarm system in order for three years at £15. 15s. per annum.

Gloucester Corporation has ordered 30 more electricity meters from Messrs. Chamberlain and Hookham.

APPOINTMENTS VACANT AND FILLED.

Messrs. Preece and Cardew, 13, Queen Anne's-gate, London, S.W., inform us that, notwithstanding that a considerable number of telegraph operators have been sent out to South Africa on behalf of the Cape Government during the present year there are still openings for a large number of good sounder clerks at salaries commencing at £120 to £145 per annum. The appointments are of a permanent nature, although they arise from changes consequent on the war. Clerks have to sign on for two years, and the salary is payable from the time of embarkation. The age limit is 19 to 25 years and candidates must be single. Second class passage is paid, out and home, promotion is fairly rapid, overtime is paid for, and a pension scheme is in operation. Altogether the prospects for these operators in South Africa are good.

An instructor in electrotyping and stereotyping, also an electrical laboratory demonstrator (two evenings per week), are required for the Northampton Institute, Clerkenwell, London, E.C. Particulars from and applications to the principal (Dr. R. Mullineux Walmsley).

Eccles Corporation require a consulting electrical engineer to advise on the extension of the electricity supply undertaking. Applications to town clerk (Mr. Wm. Henry Hickson), Town Hall, Eccles, by 17th inst. See advertisement.

Lowestoft Corporation invite applications for the position of resident electrical engineer. An advertisement contains further particulars, and applications must be sent to the town clerk (Mr. R. Beattie Nicholson) before 21st inst.

County of London and Brush Provincial Co. require an assistant engineer for one of their London stations. Applications to chief engineer (Mr. C. P. Sparks), Moorgate-court, Moorgate-place, London, E.C., by Sept. 12. See advertisement.

A practical works manager is required for an electrical accessories manufactory in the Midlands. See advertisement.

Partick Commissioners require a resident electrical engineer. Applications to town clerk, Burgh-chambers, Partick, by Sept. 24.

Belfast Gas and Electric Committee require an assistant electrical engineer. Applications to city electrical engineer by noon Sept. 10.

Accrington Corporation require an assistant electrical engineer, a fitter driver, cable jointer and switchboard attendant. Applications to town clerk by 15th inst.

Swansea Electric Lighting committee recommend the appointment of Mr. James H. Cawthra, chief assistant at Leeds, as borough electrical engineer at £300 per annum. There were 75 applications, and these were referred to the consulting engineer (Mr. E. Manville) for report. The number was eventually reduced to the following: Mr. Horace Boot, chief engineer at Tunbridge Wells (who, however, expected £400 a year); Mr. S. E. Britton, chief engineer at Barking, Essex; Mr. James H. Cawthra, chief assistant engineer at Leeds; Mr. H. Coles, of Swansea (manager to Messrs. J. C. Howell, Ltd.); Mr. P. N. Hooper, resident engineer, King's-road station, St. Pancras (London); Mr. J. D. Knight, chief engineer at Ealing; Mr. H. R. Forbes McKay, chief assistant engineer, Edinburgh; Mr. D. J. Brindle, of the Brush Company; and Mr. R. W. L. Phillips, chief assistant engineer, Bristol. The committee made the selection on Wednesday, and on the first ballot Messrs. Coles, Hooper and Boot fell out; on the second Messrs. Knight, McKay and Phillips; on the third Mr. Britton; and on the final round Mr. Cawthra was selected by 25 votes to 5.

Liverpool Electric Power and Lighting committee have made the following promotions:—Mr. A. Clough, works manager, with a present salary of £460, increasing to £500, to be assistant electrical engineer at £550, to be increased in twelve months to £600; Mr. R. S. Downe, assistant engineer, to be first assistant engineer, at £390, increasing £40 per annum to £400 (present salary £250, increasing to £300); Mr. C. H. Smith, engineer's secretary, to be office superintendent, at £150 (present salary £120); Mr. J. Stirrup, meter inspector, to be superintendent meter department, at £130 (present salary £110).

Mr. P. M'Cullough, works superintendent and general assistant of the Liverpool Tramways department, has been appointed assistant manager at £500 per annum.

Mr. H. Eady, manager at Bournemouth of the National Telephone Co., has been appointed district manager of the company for the Channel Islands.

Mr. E. Stanley Harpham has been appointed assistant in the distributing department of the Charing Cross and City Electric Co. (Ltd.)

Mr. J. F. M. Bennett has been appointed engineering clerk of works at the Reigate electricity works.

BUSINESS NOTICES.

Owing to ill-health, Mr. S. A. Parkes is retiring from the business carried on under the style of Prestwich and Burt, electrical engineers, Kingston-on-Thames. The business will be continued by Messrs. E. E. Prestwich and Leslie N. Burt at the works, South-lane, Kingston-on-Thames.

The offices of the City and South London Railway have now been removed to 71, Finsbury-pavement, E.C., over the company's Moorgate-street station.

BANKRUPTCIES, LIQUIDATIONS, &c.

The trustee (Mr. J. A. Binns, O.R., Bradford) in the bankruptcy of Arthur Blackburn (Marriott-street, Dewsbury) and James Walker (88, Dale-street, Batley Carr), trading as Blackburn, Walker & Co., electrical and mechanical engineers, Upper Lane Mills, Cleckheaton, Yorks., has been released.

Claims against B. Symmons (trading as B. Symmons & Co.), electrical engineer, 2, North-street, Quadrant, Brighton, and 14, Highland-road, Hove, Brighton, must be in by Sept. 15. Mr. R. J. Ward, 17, North-street, Brighton, is trustee.

Application for the discharge of W. J. Green, electrician, &c., 45, Birchfield-road, Aston, will be heard on Oct. 11, at the Birmingham County Court.

A second and final dividend is payable at Messrs. Carstairs, Hunter and Campbell's, 196, St. Vincent-street, Glasgow, on Nov. 1 in the estate of Wilks, Sloan & Co., electrical and consulting engineers, and J. L. Sloan, sole partner.

A meeting of the Eastbourne Electric Light Co. (Ltd.) will be held at Eastbourne on Oct. 8 to receive an account of the winding-up. Mr. H. Towner is liquidator.

Electrical Engineering Business for Sale.—The business of P. C. Middleton & Co. (Ltd.), electric light and power engineers, of Aberdeen, Edinburgh, Inverness, &c., is for sale as a going concern. Further particulars are given in an advertisement. The business includes the electricity supply plant and mains at Cults, Aberdeen. The liquidators offer the business for sale as a whole, but are prepared to consider separate tenders for the various branches. Offers to either Mr. W. R. Reid, advocate, 46A, Union-street, Aberdeen, or to Mr. S. Easton Simmers, C.A., 58, Bath-street, Glasgow, joint liquidators; or to their law agents, Messrs. Wilsone and Duffus, advocates, 146, Union-street, Aberdeen, who will supply all further information.

Plant for Sale.—Leeds Corporation invite tenders for the purchase of plant at present in use in connection with their system of electric tramways. Further particulars are set out in an advertisement. The plant, which is in excellent condition, can be inspected on application to the engineer-in-charge at the Corporation generating station. The consulting engineers (Messrs. Hopkinsons and Talbot), 26, Victoria-street, London, S.W., will supply additional information; and tenders (addressed to Tramways Committee) should be sent to town clerk's office, Town Hall, Leeds.

Messrs. Fuller, Horsey, Sons and Cassell will sell by auction at the Old Mill Works, Cowley Mill House, near West Drayton, Middlesex, on Thursday, Sept. 20, at 12 noon precisely, a quantity of engineering and electrical plant and machinery, some particulars of which are set out in an advertisement. Catalogues can be had of Messrs. Pond & Sons, 6, Butter Market, Ipswich, and of the auctioneers, 11, Billiter-street, London, E.C.

Digitized by Google

Messrs. Fuller, Horsey, Sons and Cassell will also sell by auction at 65, High-street, Kingston-on-Thames, on Sept. 26, at noon, some modern plant, machinery and stock. Additional particulars are given in an advertisement. Catalogues can be obtained from the auctioneers, 11, Billiter-square, London, E.C.

Works Premises for Sale.—Factory buildings are advertised on another page for sale or to let of large dimensions, fitted with chimney stack, hoists, combined condensing engine, &c., with canal frontage. Particulars can be obtained of Messrs. Milne, Gaff and Stirling, 63, Old Broad-street, London, E.C.

Electric Light and Power Regulators.—The Electrical Development Syndicate of Halifax has issued a new catalogue, describing and illustrating electric regulating apparatus made under the patents of Mr. Walter Emmott and others. Included in the catalogue are a number of curves of tests made on the syndicate's regulators at various installations.

"A.B.P." Accumulators.—Messrs. Ashmore, Benson, Pease & Co., of Stockton-on-Tees, forward a new price list of "Invicta" storage batteries for electric ignition and portable cells, for which advantages are claimed over dry batteries for electric ignition. The new list is accompanied by a number of testimonials from users of these batteries, supplied by the affiliated company in France.

Brown-Boveri Plant.—An interesting report is issued by Messrs. Brown, Boveri & Co. (Ltd.) on the more important installations carried out by the firm during the eight short years of the firm's existence. It is a good showing. The illustrations include several excellent views of supply works interiors, including those at Frankfort, St. Petersburg, Porta Volta (Milan), Chevres (near Geneva), Olten-Aarberg and Rathausen (near Lucerne), as well as of individual examples of generating machinery for lighting, traction, and power transmission. Some good views are also shown of interiors of the extensive works at Baden. The extent of the company's operations is indicated in some measure by the number and importance of many of the installations briefly detailed in the report.

Paris Exhibition Awards.—Elmore's German and Austro-Hungarian Metal Co. have been awarded a gold medal for their exhibit at Paris.

The Schuckert Co. was represented in four sections (No. 23, Electrical Machinery and Motors; No. 25, Electric Lighting Plant; No. 29, General Plant; and No. 118, Electrical Apparatus for Marine and Naval Purposes), and was awarded in all four sections the Grand Prix. The engineers and representatives of the firm received nine gold medals and eight silver and bronze medals.

Messrs. Ruston, Proctor and Co. received one Grand Prix, two gold medals and one silver medal; and the managing director of the company (Mr. A. Borneman) and the director and engineer (Mr. F. H. Livens) were each awarded a silver medal.

"Notes on Electric Tramways" is the title of a pamphlet issued by Mr. W. E. Kenway, 17, Burlington-chambers, New-street, Birmingham, chiefly with a view to show the advantages of the "Victor" joint and bond in tramway working.

Building Trades' Gift to the Nation.—A list of members of the electrical section of this gift who have, up to Aug. 29, promised contributions in kind or in cash to the Bisley Homes of Rest for Disabled Soldiers can be obtained from the hon. sec., Mr. W. G. McMillan, Institution of Electrical Engineers, 28, Victoria-street, London, S.W. It is pointed out that at present the response to the appeal is somewhat disappointing.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Aug. 29 to Sept. 4, with the ports of destination:—

Africa—Cape Town, £417; Durban, £174; East London, £167; Port Elizabeth, £519. *Argentina*—Buenos Ayres, £1,021 (including £296 telegraph material). *Australasia*—Auckland, £714; Fremantle, £2,342; Melbourne, £3,755 (including £903 telegraph material); Port Chalmers, £41; Sydney, £1,701 (including £404 telegraph material); Wellington, £100 (including £60 telegraph material). *Brazil*—Rio Janeiro, £196 (telegraph wire). *Canada*—Halifax, £122 (including £102 telegraph apparatus); St. John's (N.F.), £13. *Denmark*—Copenhagen, £184 (telegraph wire). *France*—Bordeaux, £30; Boulogne, £150. *Germany*—Cologne, £12; Hamburg, £980 (including £800 telegraph material). *Holland*—Amsterdam, £35; Rotterdam, £207 (telegraph material). *Hong Kong*—£37. *India*—Bombay, £68; Calcutta, £621 (including £98 telegraph wire); Madras, £42. *Japan*—Hiogo, £257 (telegraph material); Nagasaki, £169; Tokio, £135 (telegraph cable); Yokohama, £12,581 (including £11,946 telegraph apparatus). *Russia*—St. Petersburg, £352 (including £343 telegraph material). *Spain*—Seville, £280. *Straits Settlements*—Singapore, £111. *Sweden*—Gothenburg, £19 (telegraph wire); Stockholm, £269 (telegraph material). *United States*—New York, £18. *West Indies*—Jamaica, £59 (telegraph material); Trinidad, £37. Total £27,935, against £11,102 in the corresponding week last year (Aug. 30 to Sept. 5.)

PATENT RECORD.

The following list of Applications for Patents and Specifications published has been compiled for this journal by Messrs. J. C. Chapman and Co., *Chartered Patent Agents, of 70, Chancery-lane, W.C., from whom any available information in connection with Patents, Designs, and Trade Marks may be obtained.*

APPLICATIONS FOR PATENTS.

Note.—*The undermentioned Applications are not open to public inspection until after the acceptance of the complete Specification. The names within parentheses are those of communicators of inventions. When complete specification accompanies application, an asterisk is affixed.*

June 26, 1900.

11,571. H. Blumenberg, jun. London. Improvements in battery compounds.*

11,584. C. Pauthonier. London. Improvements relating to incandescent electric lamps. (Date applied for under Patents, &c., Act, 1883, sec. 103, March 30, 1900, being date of application in France.)

11,588. G. E. Kent. London. Improvements in electric railway systems.

11,597. H. G. Osburn. London. Improvements in flexible conduits for electrical conductors.*

11,609. P. H. Thomas. London. Improvements in means for protecting electrical apparatus from abrupt changes in static potential. (Date applied for under Patents, &c., Act, 1883, sec. 103, Nov. 27, 1899, being date of application in United States.)

11,610. (Exactly the same as 11,609.)

11,620. H. F. Joel, senior. Essex. Improvements in dynamo electric machines and electric motors.

June 27, 1900.

11,659. M. Haase and E. Röder. London. An improved cutout plug.*

11,677. H. C. Leake. London. Improvements in apparatus relating to the parallel running of alternate current machinery.

11,692. H. G. Nicholson. London. Improvements in or connected with electrical tramways or railways.

11,695. W. L. Wise. London. Improvements in alternating-current watt-meters. (The Union Elektricitäts-Gesellschaft, Germany.)

June 28, 1900.

11,704. W. E. Burnand. Sheffield. New or improved electric brush-holder.

11,709. Hardy and Padmore (Ltd.) and J. Southall. Worcester. Improvements in the construction of electric lamp pillars.

11,720. H. T. Dawson and H. A. Dawson. Coventry. Improvements in or relating to electrical ignition apparatus for exploding the charges in internal combustion motors, and for other similar purposes.

11,727. W. Kingsland. London. Improvements in or connected with electric switches having intermittent or step by step motions.

11,768. J. F. Cornuand. London. Improvements in electric light brackets or fittings.

June 29, 1900.

11,787. A. H. Hickley. Liverpool. Improvements in electrical starting and regulating switches.

11,797. The British Thomson-Houston Co. (Ltd.). London. Improvements in regulating devices for alternating electric current circuits. (E. Thomson, United States.)*

11,808. L. Cerebotani and C. Moradelli. London. Improvements in automatic switches for telegraph and telephone circuits.*

11,812. A. M. Hart. London. An improved method of fixing the china or other insulator and also conducting wire in sparking plug for ignition by electricity for gas or other explosive vapour or oil engines.

11,819. Siemens Bros. & Co. (Ltd.). London. An instrument for measuring rotary field currents. (Siemens and Halske Aktien Gesellschaft, Germany.)

11,825. J. F. Smith. Birmingham. Improvements relating to electrical installation and distribution.

11,835. E. R. Hill. London. Improvements in electro-pneumatic controlling apparatus. (Date applied for under Patents, &c., Act, 1883, sec. 103, Jan. 13, 1900, being date of application in United States.)

11,840. J. V. Sherrin. London. Improvements in means for preventing sparking in electric switches, commutators, current conductor contacts, contact breakers, and other electric devices.

June 30, 1900.

11,853. J. K. Grindred. Rochdale. Improvements in and relating to flag or banner poles or for use in connection with arc lamps or for other like purposes.

11,861. R. Kennedy. London. Improvements in or connected with secondary batteries.

11,869. H. V. Weyde. London. Electric generators for military and other cycles.

11,891. A. Baisieux. London. Improvements relating to electric traction for tramway and other similar vehicles.

July 2, 1900.

11,897. J. T. Pearson. Burnley. Improvements in trolleys for overhead electrically driven tramcars.

11,907. J. Bolton. London. An improved block or mounting for electrical gas and like fittings.

11,914. J. C. Richardson. London. Improvements in the manufacture of electrodes for secondary batteries.

11,915. G. R. Tomb. London. Improvements in and in connection with trolleys for overhead cable railways or tramways.*

Digitized by Google

11,929. F. C. F. KNAAK and J. S. CAMPBELL. London. Improvements in or relating to production of type by means of electric current.
11,933. R. LUNDELL. London. Improvements relating to the regulation of electric motors.*
11,937. F. B. STAFSING and C. EGNER. London. Improvements in telephone systems.
11,941. W. H. SCOIT. London. Improvements in electric motors and regulating appliances for turret turning, gun training, and analogous purposes.
11,944. V. F. FEENY. London. Switching arrangement for Nernst and vacuum incandescence lamps. (Allgemeine Elektricitäts Gesellschaft, Germany.)*

July 3, 1900.

11,965. A. BARR, W. STROUD and L. BECKER. Glasgow. Improvements in electric receivers and electric clocks.
11,970. J. MILNES. Manchester. Improvements in or relating to the construction of electric switches and contact makers used for electric tramways and the like.
11,991. THE BRITISH THOMSON-HOUSTON CO. (LTD.). London. Improvements in rheostats for electric motors. (J. L. Hall, United States.)*
11,997. R. RODRIAN. London. An improvement in accumulators or secondary batteries.
12,002. E. P. BARFIELD. London. Improvement for providing an automatic lock for the purpose of securing electric and other lamps in lamp holders, electric and other shades in holders, and locking couplings of a like nature.
12,003. J. WETTER. London. Improvements relating to dynamo-electric mine-exploders or apparatus for firing explosives. (L. C. Gomant, France.)*
12,016. T. J. RYAN. London. Improvements relating to electrically-propelled motor vehicles.*

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1899.

9,436. CANTONO. Electric telegraphic apparatus. (Date applied for under International Convention, Jan. 12, 1899.)
9,437. CANTONO. Electric telegraphic apparatus. (Date applied for under International Convention, April 13, 1899.)
12,249. THOMSON and WARNFORD-DAVIS. Telephone systems and apparatus therefor.
13,773. THOMPSON and WALKER. Electric traction on a road-contact or like system.
13,930. F. BRYAN and A. H. BAYLEY. Magneto-electric and dynamo-electric generators.
14,250. HUDSON and WIGHTMAN. Casings for electric light and similar cables.
14,265. WEHNER and LAUBE. Automatic signalling apparatus for electric tramways.
14,489. GILL. Coin-controlled call recording device for telephone systems.
14,501. HILLS and MATTHEWS. Electrical accumulators.
14,736. HURRELL. Winding for dynamos.
15,166. LANGDON. Form of electrically-actuated railway signal.
15,551. DAVIDSON. Means for supporting electric incandescent lamps.
15,581. JEVONS and LLOYD. Switch and ceiling rose or other like fitting for electric lighting purposes.
15,599. PARTRIDGE and ELPHINSTONE. Electric switches and like apparatus for making and breaking electric circuits.
15,744. LUCAS. Electric regulating switches.
15,807. WRIGHT. Terminals of electric batteries and the like.
15,967. KAMM. Electric arc projecting lanterns.
15,973. DAVIDSON. Direct coupling or connection of rotary fans or pumps with electric or other motors or engines driving same.
16,094. ECKSTEIN and COATES. Watchman's electric tell-tale system or apparatus.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since July 19, 1900). Price of silver 28⅝d. per oz. (Sept. 6). Consols (2¾ per cent.) 98⅜ – 98½ for money, 98⅝—99⅛ for account; 2½ per cent. 97—97½ (Sept. 6). Stocks and Shares Continuation Days, Sept. 12 and 26; Ticket Days, Sept. 13 and 27; Pay Days, Sept. 14 and 28; Mining Share Carry-over Days, Sept. 11 and 25.

AN AMERICAN COMBINE.—It is now definitely announced in the American electrical papers that a combination has been effected between the Stanley Electrical Manufacturing Co. of Pittsburg and the Northern Electrical Manufacturing Co. of Madison.

CHLORIDE ELECTRICAL STORAGE SYNDICATE (LTD.)—The annual general meeting of this syndicate was held at Clifton Junction on 28th ult., the chairman of the company (Mr. F. H. Bowman, D.Sc., F.R.S.E.) presiding. The directors' report for the year to June 30, stated that the business of the syndicate had continued to increase in a very satisfactory manner, the amount of orders received and goods manufactured being considerably greater than in any previous year. The capability of production at the works had been taxed to the utmost, and a large volume of orders had either gone by or been refused owing to inability to execute them within a reasonable period. To meet the continually increasing demand considerable extension of the works and plant is becoming an imperative necessity, as also the provision of additional working capital. Negotiations have been entered upon for acquiring additional land adjoining the present works. The profits for the year, after providing for debenture interest, amounted to £8,649. 15s. 5d., which the directors considered satisfactory, when the large increase in the cost of raw material and the conditions of production which obtained during the year are taken into consideration. Those, together with the execution of contracts arranged in 1897 and 1898, previous to the advance in prices, had seriously militated against the year's profit. After writing off from several accounts £4,391. 2s. 1d., there remained a balance of £4,258. 13s. 4d., and £7,026. 10s. 5d. brought forward, making £11,285. 3s. 9d. The directors proposed to carry forward the balance, out of which a dividend may be paid at their discretion. The report and accounts were adopted, the retiring director (Mr. J. S. Baker) and the auditors re-elected, and votes of thanks to the chairman and directors, and to Mr. Grindle (the general manager), the secretary and the staff, terminated the proceedings.

CLONTARF AND HILL OF HOWTH TRAMROAD CO.—The annual meeting was held in Dublin last week. The report stated that the opening of the line, which was delayed owing to the difficulty of getting rolling stock delivered, took place on July 26 last. The traffic had been satisfactory, and promised well for the future of the undertaking. The chairman (Sir F. Brady) said the receipts up to the present (for four weeks and five days) amounted to £1,078, and they carried 95,000 passengers. They had now their full supply of cars delivered, and hoped to be able to handle any traffic that might arise. The Howth line had to depend chiefly on summer traffic, but as the capital of the company was small and the working expenses comparatively low, the shareholders might look forward to satisfactory dividends out of the summer traffic alone. Under their special act the tramroad was the company's property for ever and not for a period of years, which made their property more than usually valuable. The whole of the share capital of £50,000 and £21,000 out of £25,000 debentures were issued. £45,000 had been called up on the shares. The Great Northern Railway Co. were constructing an electric tramroad round the Hill of Howth, which it was expected would be opened for next season's traffic. This line would greatly increase the attraction of the district, and consequently improve the traffic on their line, which in turn would assist the Great Northern Company's line. The report was adopted.

COMMERCIAL CABLE CO.—A quarterly dividend of 1¾ per cent. has been declared payable on Oct. 1.

HONG KONG ELECTRIC CO.—The annual meeting was held at Hong Kong in July. The chairman (Mr. C. S. Sharp) moved the adoption of the report and accounts, which showed steady progress during the year. The principal increase had been from the incandescent lighting service, the arc lighting remaining almost stationary. Expenses had increased, but coals did not show any material advance. The capital of the company had been increased to $600,000, in 60,000 shares of $10 each. Of the 30,000 new shares offered to shareholders 25,896 were taken up, and $2 per share had been called up and paid on them. That had provided sufficient capital for their present purposes, but it might be necessary to provide for further financial requirements later in the year by calling up a further amount on the issued shares, and disposing of the 4,104 shares not then taken up. Several additions had been made to the company's plant during the year. The profit on working account amounted to $43,596.62, and the balance at credit of profit and loss account was $18,216.36. It was proposed to appropriate this as follows: Dividend of 7 per cent. per annum ($22,812.72), depreciation $24,354.23, and to carry forward $1,049.41.

MARCONI'S WIRELESS TELEGRAPH CO. (LTD.)—An extraordinary meeting of this company was held on Wednesday to receive the directors' statement on the present position of the company, and regarding a proposed issue of further capital. Major S. Flood Page presided, and said the directors had resolved to issue 25,000 shares, and, in acordance with the promise given at the meeting in 1898, they were prepared to issue 25,000 shares pro rata to the shareholders at £3 per share. They had entered into a provisional agreement with an important London financial firm who were prepared to guarantee 12,500 of the 25,000 shares at £3 each, and to take at that price such of the 12,500 shares as were not applied for by the shareholders, in consideration of their being paid a commission of 5s. per share on the 12,500 shares, and in further consideration of their having a call at £3. 10s. each up to March 31, 1901, on such of the remaining 12,500 shares as were not taken up by the shareholders. The directors regarded the proposal as beneficial to the company, and the present meeting had been called to discuss it. He pointed out that it was not the directors' estimate of the value of the shares, but a bona fide offer from a firm of considerable financial eminence and very great financial strength, and he thought this estimate of the cash value of the business was in itself a testimonial to the company. Many inaccurate statements had been made by newspaper correspondents as to what the company were going to do in the Navy. They had contracted for the fitting up of the apparatus on 28 ships and four land stations. An officer in the Navy, who had been experimenting, could not get beyond 25 miles, but the Admiralty required the company to supply instruments to work at a distance of 90 miles. There would soon be other land stations which would enable the Admiralty, practically, to talk from Dover to the Scilly Islands (about one-fourth of the coast line), and no doubt they would soon wish it extended along the whole coast, and he thought the mercantile marine would soon have to follow suit. It had been stated that it was easy to tap the wireless telegraph, but their previous experience had proved that the instruments could be so tuned that this would be impossible. They were also in treaty with a foreign government for the application of the company's system to its navy. That business, if carried to a successful issue, would be very profitable to them.

MATHER AND PLATT (LTD.)—The ordinary general meeting was held on Friday last. The directors' report stated that the net profit for the

Digitized by Google

year ended June 30, after allowing for depreciation and directors' remuneration, was £71,655. Adding £4,523 brought forward there was an available total of £76,178. The preference dividend for the half-year to Dec. 31 absorbed £8,126. Out of the balance (£68,052) the directors recommended dividends at the rate of 5 per cent. per annum on the preference shares (£8,126), and 7 per cent. on the ordinary shares for the year to June 30 (£28,000). £25,000 has been transferred to reserve and £6,925 carried forward. The report and accounts were adopted, and the payment of the dividends authorised. The chairman (Mr. W. Mather, M.P.) said most engineering firms had been caught by the rise in prices of materials during the past year or 18 months. Up to the present the company had not to any great extent been able, nor had they been inclined, to make demands upon their customers to share the burden of such increase, being of opinion that it was unwise to disturb the relations between themselves and their old customers in particular unless there was the best ground for believing that the rise would be more than temporary. They looked forward to the future with confidence, and had consequently acquired an additional 50 acres of land eligible for the development of large engineering works, being bounded by railways on one side and possessing water communication on the other. Seeing the advantages now possessed by the youth of the nation in the public elementary schools, and in the secondary and high-class technical schools, the directors looked forward to the time when the engineering trades of England would command the services of quite an army of young men who were not only highly trained for the carrying on of a great technical industry, but were men of character, devoted to duty, earnestness of purpose, and animated by the noblest ambition to make their country greater in the future than it had been in the past.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee has appointed 10th inst. a special settling day for the further issue of £125,000 3½ per cent. Mortgage debenture stock of the *Metropolitan Electric Supply Co.* (*Ltd.*), and has ordered the same, as well as the further issue of 21,902 £3 fully-paid shares (Nos. 32,099 to 54,000) of *Crompton & Co.* (*Ltd.*) to be quoted in the official list. Application has also been made to the committee to appoint a special settling day in, and to grant a quotation to, the further issue of 50,000 £10 shares of the *Eastern Extension, Australia and China Telegraph Co.* (*Ltd.*), and to allow the 4 per cent. debenture stock of the *Western Telegraph Co.* (*Ltd.*) to be quoted in the official list.

TELEGRAPH MANUFACTURING CO. (LTD.)—The transfer books of the preference shares will be closed from 15th to 29th inst. inclusive, for the payment of the dividend due Oct. 1.

NOTES.

As we go to press, the highly successful meeting of the British Association at Bradford is being brought to a conclusion, though, indeed, the practical business of reading and discussing Papers came to an end on Wednesday. Favoured by delightful weather, the members have had abundant opportunity to combine pleasure with business, this recreation being greatly assisted by new and decidedly improved arrangements for the various excursions. As regards the electrical Papers, these appear to have been quite as numerous as in previous years, especially in Section A; and on the whole they may be considered quite up to the usual standard. We shall comment in detail on several of these Papers simultaneously with reprinting them in our columns. This week we publish a short summary of the electrical proceedings, together with reprints in full or in abstract of some of the communications. The Paper by Prof. J. CHUNDER BOSE, of which we commence a reprint, and on which we comment in our leading article, is worthy of careful study; and there is a useful Paper descriptive of a new standard resistance which is deserving of attention from our scientific readers.

YEARS ago, experiments were made in telegraphing across rivers and streams without crossing them with wires. Earth plates were sunk at a considerable distance apart on one side of the river, and facing them were similar plates on the other side. Some of the lines, when a current flow was made to pass between the earth plates on one side, traversed the river, and noticeable currents could be obtained by connecting the two earth plates on the other side through a sensitive instrument. As the telephone is the most sensitive means of detecting minute currents, it has been employed as the receiver in this method, and vibratory currents have been sent at the transmitting end. Sir WILLIAM PREECE's so-called electromagnetic system of wireless telegraphy consists of extending two lengths of wire parallel to one another on each side of a channel, earthing these at both ends, and connecting in circuit with one a source of vibratory current, and in circuit with the other a telephone. On comparison, however, it is seen that the two systems really employ identical means (parallel lines terminating in earth plates) to the same end, and it is probable that the result is due to a combination of conduction and induction effects. Whether inductive or conductive, it is also apparent that if a sufficiently large proportion of the transmitted current can be obtained in the receiving circuit, articulate speech instead of mere musical (or unmusical) notes might be transmitted by this method. The experiments made by Sir WILLIAM PREECE and Mr. GAVEY (described in a Paper read by Sir WILLIAM at the British Association, an abstract of which is given in another column of this issue) have proved that telephonic communication is possible by this means, provided the length of the lines or the distance between the two earthing points which are on the same side of the channel, is sufficiently great.

THIS result adds to the importance of a well-known problem in telephony—viz., that of designing a microphone for a larger current than that suitable for the instruments now in vogue. The employment of larger currents would, in ordinary telephony, permit of the reduction of the sectional area of the line wires, or, what is perhaps more important, enable less sensitive receivers to be employed and so diminish the disturbing effects due to induction from telegraph, lighting and power circuits. In wireless telephony, according to the

Digitized by Google

system described, the possible employment of larger currents is of still greater moment, since only a certain small fraction of the original current reaches the receiving instruments in each case.

Several attempts have already been made in the direction required, but none appear to have met with sufficient success to have led to the adoption of a new class of instrument by the large telephone users in various countries. Many carbon microphones in multiple have been tried, as also the effect of placing the microphonic contacts in vacuo, which is said to do away with the sparking that otherwise sets in when a certain current has been attained. There appears room for experiment with other substances than carbon—say, for instance, granules of a non-arcing metal such as zinc. Some "loud-speaking" telephones are exhibited at the Paris Exhibition, which probably are based on the principle of using large currents; but these are disappointing, as the voice is undoubtedly distorted, and in all of them is frequently most indistinct. This may be due in a large measure to the megaphone employed for making the receivers speak out, but no provision was made at the exhibition for testing the instruments with shunted receivers, and we were unable to obtain any useful particulars of the construction of the microphones.

Of the proceedings at the Bradford meeeting, outside the purely electrical sections, we may note in particular the presidential address of Sir George S. Robertson to the Geographical Section. An abstract of this address appears on another page. Sir George took for his theme "The British Empire," and started by emphasising the necessity for patriotism before true cosmopolitanism can be attained by the geographer. To this teaching no exception can be taken, but when Sir George expanded his theory and applied it to submarine cable enterprise, he seems to have wandered wide of the mark. Referring to the immense importance of the great submarine lines of telegraphs in relation to the bringing together of the scattered portions of our empire, we are pleased to see that an ungrudging meed of praise was bestowed upon the great part played in the extension of submarine telegraphy by the late Sir John Pender, whose untiring and unselfish efforts to advance our imperial interests will, we predict, be more fully and generously recognised when the inside history of our national advance during the latter half of the nineteenth century comes to be written. We, however, take strong exception to the "lessons of the past" as depicted by Sir George Robertson. It is grossly untrue, and far from patriotic, to aver that "the power of the great telegraph corporations enables them to treat public opinion with indifference," or that "boldness and foresight in finance are naturally less prominent features in the management than contentment with a high rate of interest on invested capital." And what can be said for the statement: "If it were a question of the added security or the close coupling up of the empire on the one hand and a loss of profit (however splendid the dividends might still remain) on the other, we know what would be the result of the deliberations of the companies." Sir George wished his hearers to believe that the imperial would be sacrificed to the purely commercial aspect of such a question, but in doing so he cast an absolutely unwarranted insult upon the men who have engineered the great British submarine cable industry. We emphatically deny that these men, or the shareholders who have trusted them, have reaped such rewards of their boldness and farsightedness, and of their faith in the success of their enterprise, in spite of the great disappointments of the early days, as would justify such an expression of opinion as Sir George S. Robertson has chosen to publish.

If patriotism means, as is generally understood, the placing of the interests of your country before all things, the pioneers of the telegraph have done their country yeoman service. They have made the telegraph cable industry for half a century a purely British industry; have placed at the service of the State the most perfect system of intercommunication the world has ever known: have, in fact, provided the grand and glorious British Empire with a telegraph service which is the admiration of the whole world, whatever its self-constituted critics and those who have a particular axe to grind may say to the contrary. It is, in truth, the main complaint of foreigners that the service is too patriotic. It is surely not to the discredit of those who have accomplished this great work that such results have been secured without ruining those who have provided the financial support necessary for so vast an undertaking. It is quite untrue, as was shown in the statement presented to the shareholders of the Eastern Telegraph Company, in July last, by the Marquis of Tweeddale, to assert that an unusually high rate of interest is earned or paid on the capital of the Associated Companies, who are obviously the target for Sir George Robertson's remarks. We commend the speech of the Marquis of Tweeddale, here referred to, to the attention of Sir George Robertson and those who think with him, and especially so far as it deals with the Indian rates. It is, further, demonstrably untrue to say that increased profits have invariably followed reduction in cable rates. We have by no means exhausted the erroneous statements—to put it mildly—to which Sir George has given publicity, and it is time these haphazard and misleading statements were laid by the heels.

It is passing strange that it should be necessary, but so it seems to be when discussing the future of oversea telegraphs, to spread broadcast against the existing owners of these lines the most glaring untruths. We can only assume that the statements are made "for effect." But surely the question of the purchase of the telegraphs by the State, the price to be paid, and other matters connected with the future position of ocean telegraphs can be discussed without calling in question the patriotic *bona fides* of those who have for many years ably conducted a difficult enterprise, requiring skill and tact of a high order. We, therefore, much regret that a British Association meeting should also be made the occasion for a most unmerited attack upon many honoured names in science: for it must be remembered that not a few of those who have shared in the prosperity of these commercial undertakings are numbered among the best known members of the scientific professions. Sir George S. Robertson owes a public apology to the men who represent the most patriotic industry of this country.

With a rapidity comforting indeed to advocates of electric traction the old order changeth and is giving place to the new as regards passenger traffic between the City and the western suburbs along the line of the "Tuppenny Tube." We daily note the enormous volume of traffic pouring into and out of the stations, and the ample accommodation left unused in the disconsolate-looking 'busses, and are convinced. But the figures published last Wednesday in the *Financial News* are not less convincing, for they indicate the falling off in omnibus receipts which has taken place. In the week ended August 16, for example, the decrease in receipts for the two principal omnibus companies, as compared with the corresponding week last year, amounted to over £4,600. We are sorry for the omnibus companies; but the march of civilisation is inevitable—and the London omnibus is *not* a civilised vehicle.

Erratum.—In the title of our reprint of Dr. Larmors' Presidental address last week, p. 732, for "A Section" read "Section A."

British Association Meeting for 1901.—Prof. A. W. Rücker, Secretary of the Royal Society, has been nominated President of the British Association for next year, when the meeting will be held at Glasgow.

Underground Railway for Buenos Ayres.—A New York contemporary states that a concession has been granted for an underground electric line in Buenos Ayres to Carlos Bright, an American engineer.

Cable Interruptions:—	Date of Interruption.
Latakia—Cyprus	June 21, 1899
Cayenne—Pinhieros	Oct. 11, 1899
Tangier—Tarifa	Jan. 3, 1900
Ceara—Maranham	Feb. 20, 1900
Pará—Maranham	Mar. 2, 1900
Môle-St. Nicolas—Cap Haitien	Mar. 7, 1900

The Society of Model Engineers.—A monthly meeting of the Liverpool branch of the Society of Model Engineers was held at the Balfour Institute on September 5th, when a collection of models and also a large number of detail drawings of model locomotives were on view. The next meeting of the Society will be held in the recreation room at the Balfour Institute, Smithdown-road, Liverpool, on Wednesday, October 3rd, at 7:45 p.m.

The Galveston Disaster.—A notice issued by the Berne Bureau intimates that, owing to the terrible hurricane which has visited Galveston (Texas) and district, messages over the Mexican Telegraph Co.'s lines are subject to delay, and the traffic to Mexico and beyond will go by the land lines of the Mexican Government. The cables of the Mexican Telegraph Co. are worked in conjunction with those of the Central and South American Telegraph Co.

Telephone Time Service.—A new arrangement has been inaugurated in connection with the Berlin telephone service, by means of which a subscriber can obtain a time signal every morning at nine o'clock. Subscribers wishing to receive the benefits of this system must pay an extra subscription of 10s. per annum, and must see that their telephone is not in use at about the time the signal is expected. The signal is given to all subscribers precisely at nine o'clock by their bells ringing, and continuing to do so for about one minute.

Proposed Tramway Subways at Chicago.—Plans have been drawn up for a system of tramway subways underneath some of the principal streets in Chicago. The cost of the construction is estimated at approximately £400,000 per mile. It is proposed that the subways should be built by the city, and that arrangements should be made for the tramway companies to run their cars through them rather than on the roadway overhead. Provision is to be made in the subways for water and gas pipes and all kinds of underground wires, conductors, &c. The arrangement of the subways is in the form of six loops, so constructed that passengers can easily transfer from one loop to another at definite points. The cars would circle continuously in these loops. The estimated depth of the subway, viz., from the road level to the drain pipe beneath the subway, is 32 ft., and electric pumping plant would be erected for draining the subways into the Chicago River.

Tramway Exhibition Humour.—The following story of an incident which took place at the recent International Tramways and Light Railways Exhibition, in London, is told by an American contemporary:—

Mr. Harold P. Brown, of New York, gave away as a souvenir a little leather purse, and enclosed therein was what looked like a $1,000 bank bond, but on examination turned out to be an advertisement for plastic bonds. The chairman of the —— City Council visited Mr. Brown's exhibit, and was much interested in the explanation of the bonding process. He had an armful of catalogues and pamphlets that he had previously collected, and Mr. Brown, noticing this, remarked that he would give him a little remembrance that he would be likely to retain when the mass of printed matter had been mislaid, and thereupon presented him with a purse, which was accepted with many thanks; but when it was opened and the folded bond inside came in view great was the chairman's indignation. "You have fallen very low in my estimation, sir," he exclaimed. "You cannot influence my vote by giving me a purse of money, sir; such proceedings may prevail in your land, sir, but not here, sir. I will have nothing more to do with you, sir." And with that he started away. Mr. Brown, however, after considerable talk, convinced him that the gift was not a bribe, and that the enclosed bond was not negotiable, and the chairman departed with the purse and his bond, with the laugh against him.

Electromotive Force of a Moving Charge.—In a note on M. Cremieu's experiment, read by Prof. G. F. FitzGerald, F.R.S., before Section A of the British Association at Bradford, it was stated that M. Cremieu has shown that, if his experimental methods can bear criticism as well as they seem to do, there is no induced electromotive force on a coil of wire surrounding a rotating disc when the strength of an electric charge on the disc is changing. He has deduced from this the conclusion that there is no magnetic induction through the disc due to the moving charge, such as Rowland's experiments showed. Prof. FitzGerald's note was intended to point out that too little is known of the theory of the ethereal effects of a charge of electricity force to move by mechanical actions for us to be quite sure that both M. Cremieu's and Rowland's observations may not be true, *i.e.*, that it is possible that a charge of electricity, while it is being accelerated by moving matter, may produce such an action on the surrounding ether as to neutralise the electric force that would otherwise be produced by the changing magnetic induction due to the moving charge.

University College, London.—In conjunction with the Technical Education Board of the London County Council, classes have been arranged by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., to be held during the ensuing winter in the Pender Electrical Laboratories, University College, Gower-street, W.C. These classes are intended for students practically engaged in the electrical trades or allied industries during the daytime, and not for the ordinary student who can attend day classes. (i.) A course of ten lectures, followed by laboratory practice in advanced electrical measurements, by Prof. J. A. Fleming. These lectures will comprise a theoretical and practical treatment of advanced methods in electrotechnical measurements, of the character required in electrical works and factories, in connection with electric lighting and electric power transmission. The treatment of the subject will be adapted for those who have already made some progress in practical electrical knowledge, but not for those who are entirely ignorant of electrical theory. The lectures will be given from 7:15 p.m. to 8:15 p.m. on Wednesdays from Oct. 17 to Dec. 19, 1900, inclusive. Each lecture will be followed by 1½ hours' practical work in the laboratory. (ii.) A course of lectures on the Electric Motor and its Application in Electric Traction, by Prof. C. A. Carus Wilson, M.A. This course will comprise ten lectures given on successive Wednesdays from Jan. 23 to March 20, 1901, inclusive. The lecture hour will be from 7:30 p.m. to 8:30 p.m. Each lecture will be followed by an experimental demonstration or by a class for the practical working of numerical examples in connection with the subject.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Lightning Photographs.—It is well known that when a flash of lightning is photographed by a camera kept in a constant state of motion the photograph usually shows the flash broadened out or made multiple. Three different explanations of this effect are conceivable. The motion of the camera, held in the hand or against the chest of the observer, may render the image of the flash diffuse owing to the discharge not being instantaneous. That is, however, not likely. A more probable explanation is that a large number of successive discharges take place along the same path, and this would in effect lengthen the time of the discharge. Lastly, we know from Toepler's researches on globe lightning that the conducting path created by a lightning flash may be carried forward and distorted by the wind. C. Forch has examined some photographs in the light of these various hypotheses. The photographs were taken at dusk, and show the outlines of houses as well as the flashes. One of the photographs show the path of the flash broadened, and the outlines of the buildings broadened in the same direction and to the same amount. This would testify to the permanence of the path, as well as the finite duration of the flash. The other photographs are not so conclusive. It appears certain, however, that distortion by wind plays no part in the phenomena.

[C. Forch, *Physikal. Zeitschrift*, Sept. 1, 1900.]

Non-Permanence of Weight.—The whole system of modern chemistry is based upon the axiom of the indestructibility of matter, and that indestructibility is proved by the permanence of the weight of a given substance through all the physical or chemical changes it is made to undergo. Any experiments, therefore, which shake our belief in that primary property of matter must have a far-reaching effect. Landolt's classical researches in 1893 (for which see the *Zeitschrift für Physikalische Chemie* of that year) embodied the first work done with all the modern instruments of precision. Certain minute changes of weight were then placed in evidence, and these have since been confirmed. A. Heydweiller has endeavoured to trace some connection between the change of weight and the changes in other physical properties, such as magnetic permeability, electrolytic dissociation, and material or optical density. He has failed to trace any such connection, though he has distinctly established a diminution of weight of about 1 part in 50 million in a number of reactions, such as the mixture of copper sulphate with water, where a loss of weight of 1 milligramme was observed. Researches such as these take place in the extreme borderland of science, but the logical outcome of the results would be nothing less than the destruction of matter.

[A. Heydweiller, *Physikal. Zeitschrift*, August 25, 1900.]

Hall Effect in Gases.—According to the modern ionic theory, the Hall effect may be calculated from the difference between the positive and negative ionic velocities, and such a calculation, carried out in the case of electrolytes, indicates that no appreciable effect can be expected in them. In gases the electromagnetic transverse and longitudinal effects are very appreciable, but no quantitative results can be as yet obtained owing to the many complications which arise. One case of gaseous conduction, that of flame gases, is, however, sufficiently simple and well known to yield results of theoretical importance. In flame gases the transport of electricity is carried out by electrolytically dissociated ions, whose velocity is about a million times greater than in electrolytes, and shows a considerable difference in the positive and negative ions. E. Marx has therefore studied this case experimentally and has succeeded in finding a Hall effect which is distinctly appreciable, though necessarily small. He used a flat Bunsen flame, into which a fine spray of the solution of some alkaline salt was blown. He found that as the atomic weight of the metallic base of the salt increased, so did the velocity of the ions, and the cæsium ions had therefore the greatest velocity. The Hall effect in electrolytes will probably remain too small for measurement.

[E. Marx, *Ann. der Physik*, No. 8, 1900.]

Production of Röntgen Rays.—When a spark-gap is introduced in a Röntgen-ray circuit, the maximum gaseous pressure at which X-rays can be produced is increased. According to A. Winkelmann, the maximum pressure attainable depends upon the length and position of the spark-gap, the nature of the gas, and the dimensions of the tube. At the highest pressures, Röntgen rays are only seen when the spark-gap lies between the cathode and the induction coil. As the pressure decreases, rays begin to appear also when the spark-gap is next the anode; but they are feebler than in the other arrangement. At low pressures the influence of the position of the spark-gap becomes less pronounced, and finally disappears. Hydrogen yields Röntgen rays at greater pressures than air or carbonic acid. The latter allows the least pressure, but its difference from air in this respect is not great. The admissible pressure may be considerably increased by making the tube narrow. Thus in a tube only 5mm. in diameter it was found possible to increase the pressure of the air contained in it to 10mm. of mercury, and yet obtain effective X-rays. But a further narrowing has the contrary effect, and in hydrogen the maximum pressure of 30mm. is already reached in a tube 1cm. in diameter.

[A. Winkelmann, *Ann. der Physik*, No. 8, 1900.]

Magnetic Behaviour of Liquid Crystals.—When O. Lehmann announced his discovery of liquid crystals, 10 years ago, he was greeted with a chorus of doubt and disapproval, but he has since succeeded in proving that all the characteristics of crystallisation which his liquid crystals do not possess cannot logically be made part of the definition of a crystal. The only general characteristics of crystals are that they are not isotropic, and that they possess a molecular directive force which governs their shape and the distribution of accretions. The directive force is preserved by means of the surface tension, and crystals may therefore be liquid or solid, but they cannot be gaseous. Liquid crystals may be produced by depositing solid crystals from a mother liquor on the cover glass of a microscope and gently heating the latter until the fusing point is exceeded. Their optical properties can then be conveniently studied. Their double refraction and dichroism indicate a difference in the dielectric constant and the electric conductivity respectively in different directions, but these differences cannot be placed in evidence owing to the electrostatic rotations which free crystals immersed in a liquid undergo in an electrostatic field. In a magnetic field, however, the crystals show a distinct tendency to place their axes of symmetry normal to the lines of force. The author expects to obtain valuable results by applying this discovery to living cells.

[O. Lehmann, *Ann. der Physik*, No. 8, 1900.]

Cold Light.—The most economical light is that whose spectrum is confined to the visible rays, and which does not involve the simultaneous emission of either infra-red or ultra-violet rays. Electric light marks in this respect a distinct advance on the older methods of lighting, and electric luminescence decidedly so. But no form of light hitherto produced equals that of the glow-worm in efficiency. The light of luminous organisms only contains an infinitesimal amount of heat. R. Dubois has been exhibiting some "photo-bacterial" products at the Paris Exhibition, and he now gives some particulars of the liquid medium which best suits their development. The liquid exhibited at the Palais de l'Optique consists of water containing sea salt, glycerine or mannite, and either peptone or asparagine, with an addition of some phosphorated compound like nucleine, phosphorated lecythine, or potassium phosphate. The author gives no information concerning the species of bacteria used. He says that the permanence of the light varies with the purity of the ingredients and the ventilation and agitation of the liquid. It may last six months. A room may be lighted up with a luminosity like that of the full moon. It may be that these photo-bacteria will acquire the industrial importance of the yeast fungus, but that will probably be eclipsed by some purely physical method of generating cold light.

[R. Dubois, *Comptes Rendus*, August 27, 1900.]

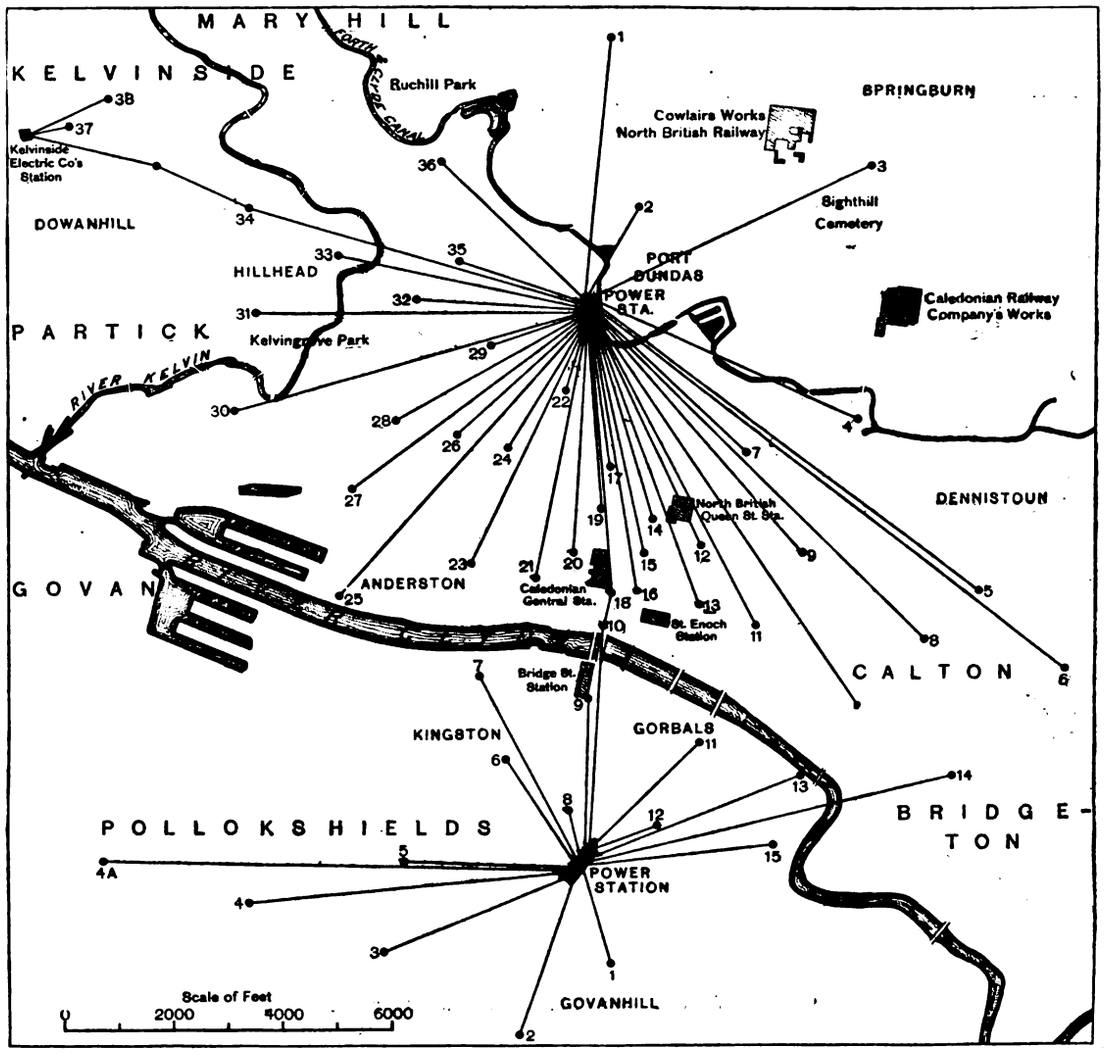
THE NEW ELECTRICITY WORKS OF THE GLASGOW CORPORATION.

Yesterday the two new electricity works of the Glasgow Corporation were opened with all the pomp and ceremony of a civic function. A large company assembled at the municipal buildings at 11 o'clock and then drove to the Port Dundas station, which was declared open by the Lord Provost (Mr. Samuel Chisholm), a gold key being presented him by the contractors. After an inspection of these works a similar ceremony took place at the South Side works, Bailie McLay being this time the wielder of the golden key. The programme also included a luncheon in the banqueting hall of the municipal building, a number of congratulatory speeches, and a presentation made to Bailie Willcox, Convener of the Works committee, by the cable contractors, the British Insulated Wire Co. and the Callender Co.



MAP OF GLASGOW, SHOWING POSITION OF SUPPLY STATIONS AND FEEDERS.

The Corporation had prepared a brochure for the occasion, describing the undertaking from its earliest days. As far back as 1882, in a Corporation gas bill, it was proposed to take statutory powers to supply electricity; but the clauses were struck out before the bill came before any of the Parliamentary committees for consideration. Three years or so before this, however, the first practical attempts towards a public supply were made almost simultaneously by the British Electric Co., at the St. Enoch's Station of the Glasgow and South Western Railway, where they laid down Gramme dynamos to light the station, and by Messrs. Crompton & Co., at the Queen-street station of the North British Railway, for a similar purpose. The stations were lighted at a fixed rate, but the expectation that a general supply business would grow up was not fulfilled, and the respective railway companies finally took over the plant for their own use entirely. In connection with St. Enoch's Station, it is an interesting fact that after various lots of new plant and different arrangements, the directors of the company have just entered into an arrangement with the Corporation whereby they take the whole of their electrical energy from the Corporation mains.

The next attempt at a public supply was made by Messrs. Muir and Mavor (the pioneers of the firm which is now known as Mavor and Coulson), who laid down a plant to supply the General Post Office in George-square. The plant was first put down on the site where the municipal buildings now stand, was then removed to the basement of the post office, and later, in 1884, permanent plant was put down in Miller-street, and the current was carried by overhead cables across the intervening buildings. This was the first post office in the United Kingdom to be lighted by electricty.

The supply from the Miller-street station was on the low-tension continuous-current at 100-volts, but at John-street, for public supply purposes, it was decided to lay down high-tension plant, so a Ferranti alternating-current plant was erected, generating and distributing at 2,400 volts, and transforming down to 100 volts on the consumer's own premises, the supply being conveyed by overhead wires. The company in 1890 applied for a provisional order to supply Glasgow generally, but the Corporation having awakened to the fact that electricity promised to be a rival to their gas supply, also applied for a provisional order, and in view of this the company withdrew their application in favour of the Corporation. The Corporation's order was granted, and subsequently the Corporation agreed to purchase the company's undertaking for £15,000.

Digitized by Google

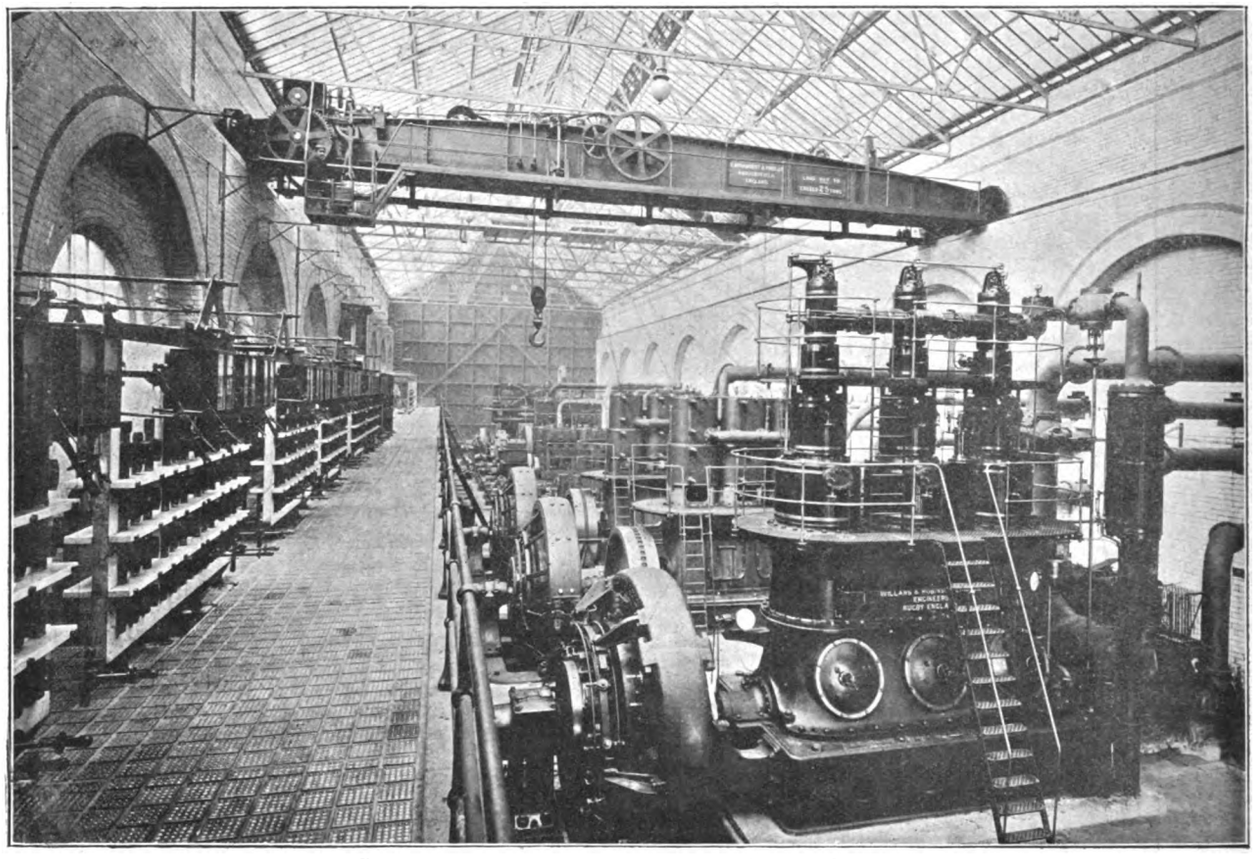
The capacity of the plant at the time was 297kw., and the number of consumers 87. A very interesting feature of this early installation is the fact that it was the first time that energy was charged on the maximum demand system. The system as used by Messrs. Muir, Mavor and Coulson differed from the Wright system, there being a fixed charge for the current with a scale of discounts increasing according as the consumption was equivalent to 301, 501, 1,001, or 1,501 hours per annum of the calculated maximum demand.

It was on March 1, 1892, that the Corporation took over the company's business. As the Board of Trade had only sanctioned the overhead system of high-tension supply until August, 1893, it was necessary to push on with the re-modelling of the system as quickly as possible. On the advice of Lord Kelvin, Prof. A. B. W. Kennedy was appointed consulting engineer to prepare the scheme for the general supply. The Corporation purchased ground at 75, Waterloo-street for the sum of £8,000, and the erection of the present Waterloo-street electricity station was commenced in the spring of 1892. The low-tension three-wire continuous-current system was adopted at the then Board of Trade limit of 200volts. Already, on Feb. 25, 1893, Lord Provost Bell was able to inaugurate the street lighting, and the supply was switched on to the consumers' mains on April 22 following. At this time the plant for the low-tension supply consisted of seven Willans units of a gross total of 1,400 H.P. to 1,500 H.P., with two Brush arc lighters, driven by two Easton, Anderson, and Goolden engines for the street lamps. The latter at first consisted of 77 Brush arc lamps, being afterwards increased to 112. The mains laid down at first were entirely on the Kennedy bare copper system. So great was the demand for current that extensions were required the following year, and two 225kw. Willans-Siemens sets were laid down. In order to make room for these plants the arc lighters were removed to the then disused John-street station, which station we may here note was, after various changes, finally closed some two or three years ago, and is now used as a store and workshop. In 1895, and again in 1896, it was found necessary to increase the capacity of the station, and in each of these years two 225kw. plants were added, after which there was no room for more. The increase of the boiler plant followed on the same lines as the engines, the original plant consisting of five marine type boilers of 300 H.P. each, another similar one being added in 1894, two 700 H.P. Babcock and Wilcox in 1895, and another of the same size in 1896.

Table showing Development of Electrical Supply in Glasgow.

Year ending May 31.	Total max. supply dem'd.	Total capacity of plant.	Maximum load.	Quantity sold.	Quantity generated.	Number of consum'rs	Revenue.			No. of public lamps.
	kw.	kw.	kw.	B.T. units.	B.T. units.		£	s.	d.	
1893	790	800	570	287,712	408,529	108	7,784	5	4	71
1894	1,684	1,250	894	702,248	854,766	378	18,015	19	2	102
1895	2,090	1,700	1,140	901,287	1,022,730	586	21,196	11	4	103
1896	2,638	1,700	1,440	1,090,959	1,279,687	855	25,862	8	6	112
1897	3,366	2,150	1,776	1,497,842	1,729,483	1,090	30,474	16	1	112
1898	4,800	2,150	2,232	2,114,036	2,619,019	1,437	36,360	14	10	119
1899	6,114	2,600	3,096	2,824,350	3,401,731	1,858	44,141	4	7	227
1900	7,732	6,402	4,258	4,250,669	5,226,818	2,852	59,762	2	0	265

A glance at the table reproduced above, from the brochure mentioned, will show at once the very rapid growth of the undertaking, and it will be noticed that with the exception of the first year not only was the maximum demand well in excess of the capacity of the plant, but the actual maximum load had in 1896 approached very closely the total capacity of the plant. To meet, therefore, the increased demand for the following year, and to cope with the peak, two large Tudor batteries were put down, each of 2,000 ampere-hours capacity and capable of being discharged in an hour if necessary, one being placed about a mile to the east of the central station, and the other about a mile to the west.



General View of Engine Room in Port Dundas Station.

When, in 1896, the electricity department was removed from the control of the Gas committee and placed under the care of a separate committee, the total inadequacy of the existing station to supply the needs of a city like Glasgow was realised. In 1896 therefore, the Corporation purchased ground at Port Dundas, an area containing 21,026 sq. yds., and bounded on the north by the Forth and Clyde Canal. At the same time ground with an area of 8,926 sq. yd. was purchased in Pollokshaws-road, and bounded at the rear by the Glasgow, Barrhead and Kilmarnock joint railway.

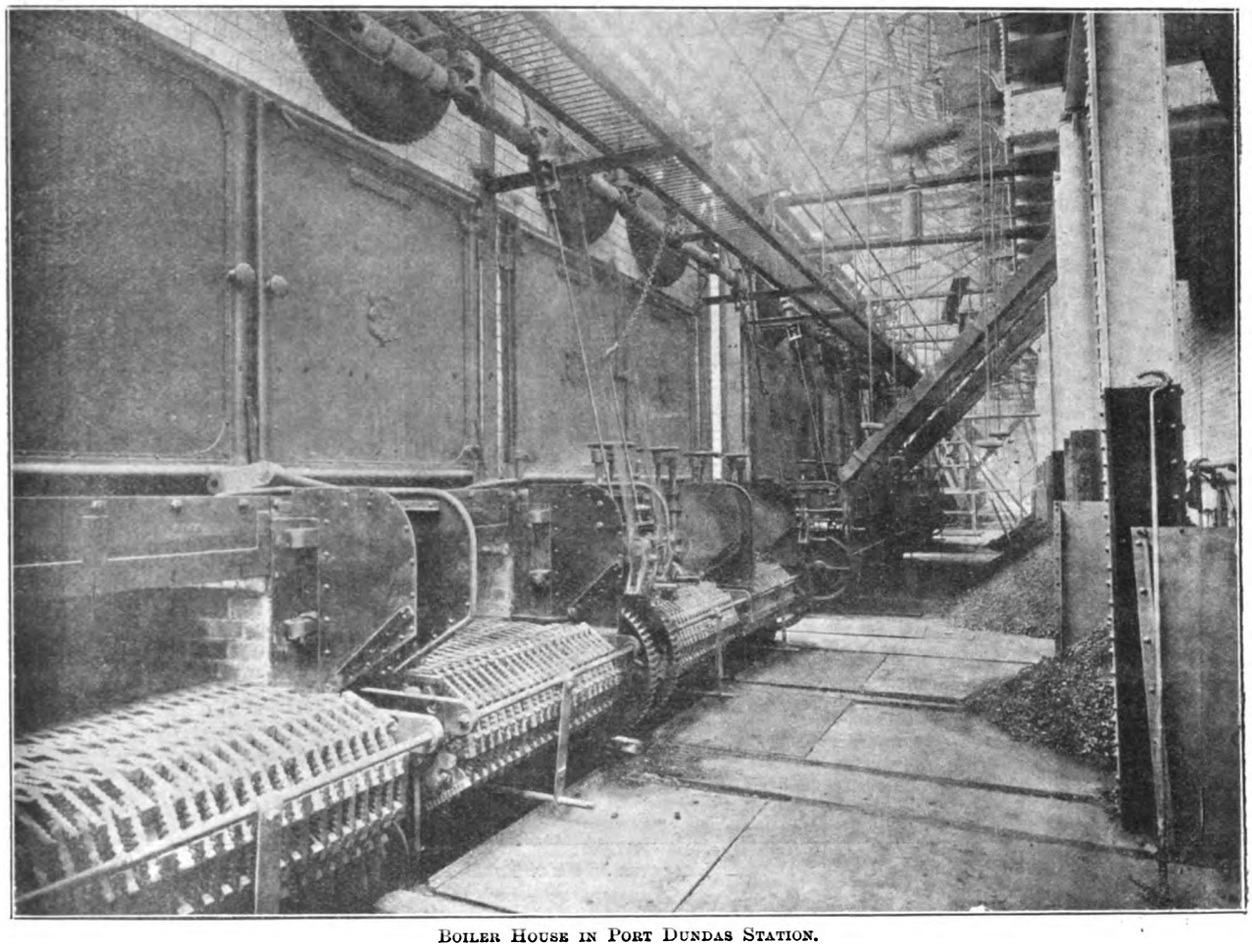
Digitized by Google

A trouble arose about this time with regard to the supply of power to the tramway department for running their cars. One cause of the friction was doubtless due to the electricity department itself, as a very animated internal discussion arose with regard to the system to be adopted in the new stations, a strong party advocating a high-tension alternating system. Had such a system been adopted it would, of course, not have been suitable for tramway purposes, and the Tramway committee contended that if the Electricity committee would have to put down special plant for tramway purposes, the Tramway committee could do it themselves equally well. However, the matter was compromised by an arrangement that for the experimental line the tramway department should lay down its own power plant; and so was inserted the thin end of the wedge which ultimately resulted in two distinct electricity departments being worked under the same Corporation. Just at this time, also, Mr. William Arnot, who had been resident engineer since the opening of the Waterloo-street works, resigned to take up a consulting practice, and the committee appointed a successor to him in the person of Mr. W. A. Chamen, who was engaged to act both as consulting and resident engineer. Mr. Chamen entered upon his duties on January 28, 1898, and immediately set about formulating his scheme for the new works, which were to embrace the whole of the city, and under his direction the Port Dundas station was planned and the erection was immediately pushed forward.

As will be noticed from the table already referred to, the winter of 1897–98 was a very serious time, principally owing to an extended period of fog which occurred in December and caused a demand beyond the capacity of the whole of the plant, including the accumulator sub-stations. It was obvious to the engineer, as the demand continued to increase by leaps and bounds, that it would be impossible to wait for the delivery of plant and the completion of the station in the ordinary course, and that therefore something had to be done to meet the load of the winter 1898–99. Advertisements were therefore issued for such plant as manufacturers might be able to deliver quickly, and as a result the first instalment of plant described further on in this article was purchased for immediate delivery. Owing to disputes in the building trade and other causes, it was quite impossible to get the permanent building completed in time, so it was decided to put down the plant on permanent foundations and erect a temporary wooden shed over it, an part of this plant was put into use in December, 1898.

While the station was being proceeded with, sight was not lost of the state of the distributing system. At the time Mr. Arnot resigned, the system was half the original three-wire system with 100 volts on either side of the middle, and half a two-wire system using the outer to supply lamps at 200 volts; this, of course, being done with the idea of introducing a three-wire 400-volt system. However, Mr. Chamen advised his committee to increase the pressure across the outer of the three-wire network to 500 volts instead of 400 volts. The difficulties in making this change from 100 volts and 200 volts consumers' pressure to 250 volts were not slight.

In August, 1899, the undertaking of the Kelvinside Electricity Co., which had previously been running with only moderate success, was purchased by the Corporation. Although this company's mains were laid for a three-wire system, the supply was only on a two-wire 100-volt system.



Boiler House in Port Dundas Station.

During the past spring and summer it has been gradually changed over to the 250-volt supply, and at the present time it is entirely supplied from Port Dundas, the Kelvinside works having been shut down to facilitate putting down new plant for the coming winter.

At present the Port Dundas works are supplying current from Bridgeton Cross on the east to Whittinghame Drux, Kelvinside, on the west; and from Springburn Park on the north to Eglinton Toll on the south. The supply at Eglinton Toll, however, is only of a temporary nature, it being used to furnish power to the overhead electric crane now in use for erecting plant at the Pollokshaws electric station. These latter works when completed, probably during the coming month, will meet all requirements on the south side of the river, and will also help to supply certain streets on the north side by feeders laid across Glasgow bridge, and also Bridgeton through a feeder laid across the new bridge. We will next proceed to descriptions of the new stations in greater detail.

(To be continued.)

THE PARIS EXHIBITION.—VI.*

(BY OUR SPECIAL CORRESPONDENT.)

Another combined continuous-current and three-phase set for the light and power supply within the exhibition is the one exhibited by the Lahmeyer Company in conjunction with the Augsburg-Nuremberg Company, and shown in Fig. 30. The two dynamos are placed on either side of the engine, which is compound, with 865mm. and 1,350mm. cylinders and 1,100mm. stroke, and runs at 94 revs. per min. The three-phase machine is of the flywheel type, the magnet wheel having a diameter of 5,800mm., and weighing about 54 tons. Figs. 30 and 31 show the general design of the machine. It is seen that the armature, which is stationary, is held in a well-designed casting, supported by cast-iron arms. The outside diameter of the armature casting is 6,920mm. (22ft. 8in.), and the whole machine weighs 115 tons. The frequency being 50 ∼ per sec., there are 64 poles bolted on to the fly wheel. These are wound with flat copper strip, placed on edge, and insulated with "presspahn." Exciting current is furnished by a small continuous-current machine carried on a bracket fixed to the outside bearing of the alternator, its armature being overhung. In order to be suitable for 500 volts pressure, the armature windings of the three-phase machine are insulated with great care, being laid in closed micanite tubes.

A peculiar method of connection is employed for the measuring instruments. Part of the winding of each phase of the alternator armature is not connected up to the remainder, but is connected instead to the primary of a transformer, whose secondary is in series with the main part of the armature winding, and thus takes the place of the disconnected coils. The voltmeter, however, is connected between the terminals of this smaller section of the winding, and the ammeter is in series with these coils in the primary circuit of the transformer. No high pressure fuses or cut-outs are employed on this switchboard, the makers trusting to the self-induction of the dynamo and the cut-outs on the exhibition distributing switchboard to prevent damage by short-circuit.

The continuous-current machine has a capacity of 350kw. (400 on overload) at 550 volts. As will be seen in Fig. 32, its most noticeable feature is the width of the armature compared with that of the pole-pieces. The armature is drum-wound with rectangular copper bars, and its diameter is 2,400mm. Each winding is bent from a single bar, so as to have as few joints as possible. The armature core is slotted to receive the windings, and lined with mica and "presspahn," and brass segments (which are screwed on and are easily removable) hold the bars in place against the action of centrifugal force. As seen in Fig. 32, there are 12 pole-pieces radiating inwards from the main casting. These poles are of steel. The armature weighs 12 tons, and the whole dynamo 25 tons.

The fourth generating unit for the exhibition supply is the Borsig—Siemens & Halske set shown in Figs. 33 and 34. The triple-expansion engine is a vertical two-crank one, with two low-pressure cylinders, the cranks being set at 180deg. Its main dimensions are: H.P. cylinder 760mm., intermediate cylinder 1,180mm., L.P. cylinders both 1,340mm., stroke 1,200mm., speed 90 revs. per min., and output about 2,500 H.P. when running condensing and with steam at 14 atmospheres pressure. The crank-shaft is in two parts, and at one end of it is a crank disc driving two coupled single-acting air pumps under the floor, for the jet condenser. At the other end of the crank-shaft is the dynamo, whose armature is supported by two large bearings (with ring lubrication), which can be moved along their bed-plates. The exciter is also coupled to the crank-shaft, and is placed beyond the outside bearing of the alternator.

The bedplate of the engine is in two parts, joined together by flanges and bolts; and, between the two main bearings on each portion, the casting is made slightly concave to catch waste oil. Two small rotary pumps, driven through spiral springs of steel wire from the crank shaft, convey the oil to a filter, whence it is again distributed. Between the bedplate and the larger dynamo bearing, a 41-ton flywheel is hung on the crank-shaft, and its rim is toothed for barring, which is

Digitized by Google

done by a motor. The two massive standards holding the slide bars are bolted to the bedplate both internally and externally, and are stiffened by the two forged steel pillars seen in front in Fig. 33. On these standards are placed the two low-

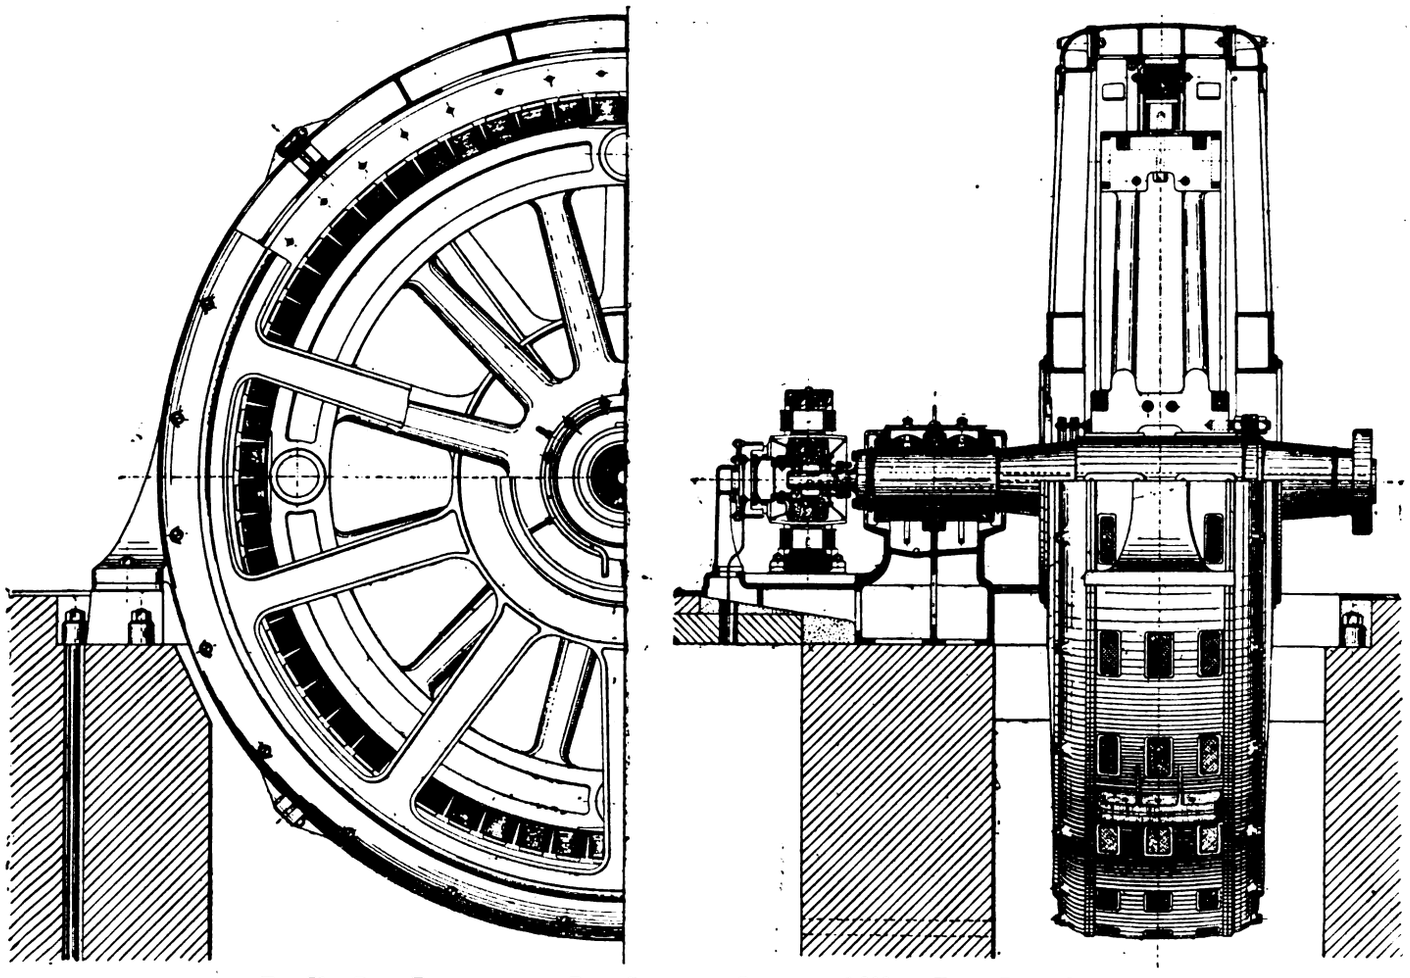

FIG. 31.—PART ELEVATIONS AND PART SECTION OF LAHMEYER 1,000KW. THREE-PHASE DYNAMO.

pressure cylinders, which are securely bolted together. Each of these cylinders is jacketed with low-pressure steam, and the

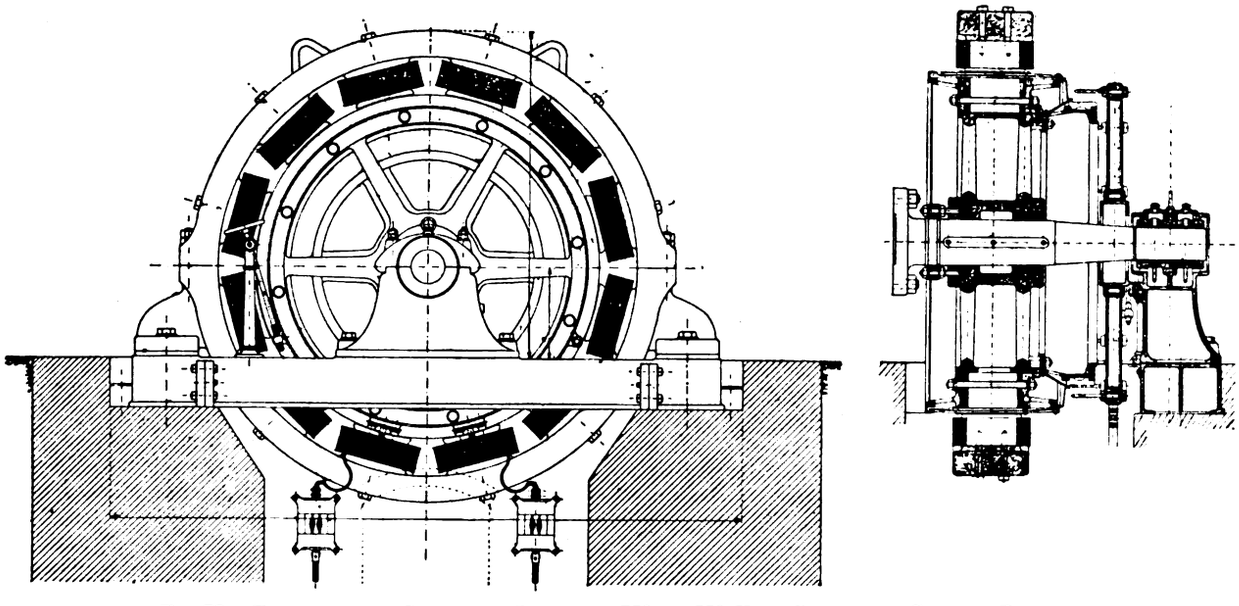

FIG. 32.—ELEVATION AND SECTION OF LAHMEYER 350KW. 550 VOLT CONTINUOUS CURRENT DYNAMO.

intermediate and high-pressure cylinders with steam at the intermediate and high pressures respectively. The high-pressure piston has Ramsbottom cast-iron rings, and the pistons of the other cylinders Buckley rings of the newest design. The pistons themselves are of steel.

Double-seated valves, constructed according to a recent patent of Collmann's, Fig. 35, are employed for all the cylinders. They are fitted on extensions of the cylinder castings at the side of the L.P. cylinders and on the hinder side of the other cylinders. To actuate the valves a horizontal shaft, supported in six bracket bearings behind the L.P. cylinders, is driven by bevel gearing from the crank shaft

Digitized by Google

through the intermediary of an inclined spindle on which also the governor is fixed. The admission and exhaust valves of all four cylinders are moved by trip gear driven by eccentrics on the above-mentioned horizontal shaft. The governor acts on the trip gear of the admission valve of the H.P. cylinder in more or less the usual manner, and the other valves can be adjusted by hand. One eccentric suffices for each admission valve and the corresponding exhaust valve, on the H.P. and intermediate cylinders; while each of the valves of the L.P. cylinder is driven by its own eccentric. The speed of the engine can be adjusted while the engine is running by means of a supplementary spring in the governor, controlled by a hand-wheel.

The rotating masses of the connecting rods, &c., are balanced by counterweights bolted on to the crank shaft. Marine types of connecting rods and crossheads are employed, and the piston rods for the pair of cylinders on each side of the machine are in one piece. Oil is led under pressure to all the stuffing boxes, and for the remaining parts of the engine, oil is pumped up from below to a reservoir on the

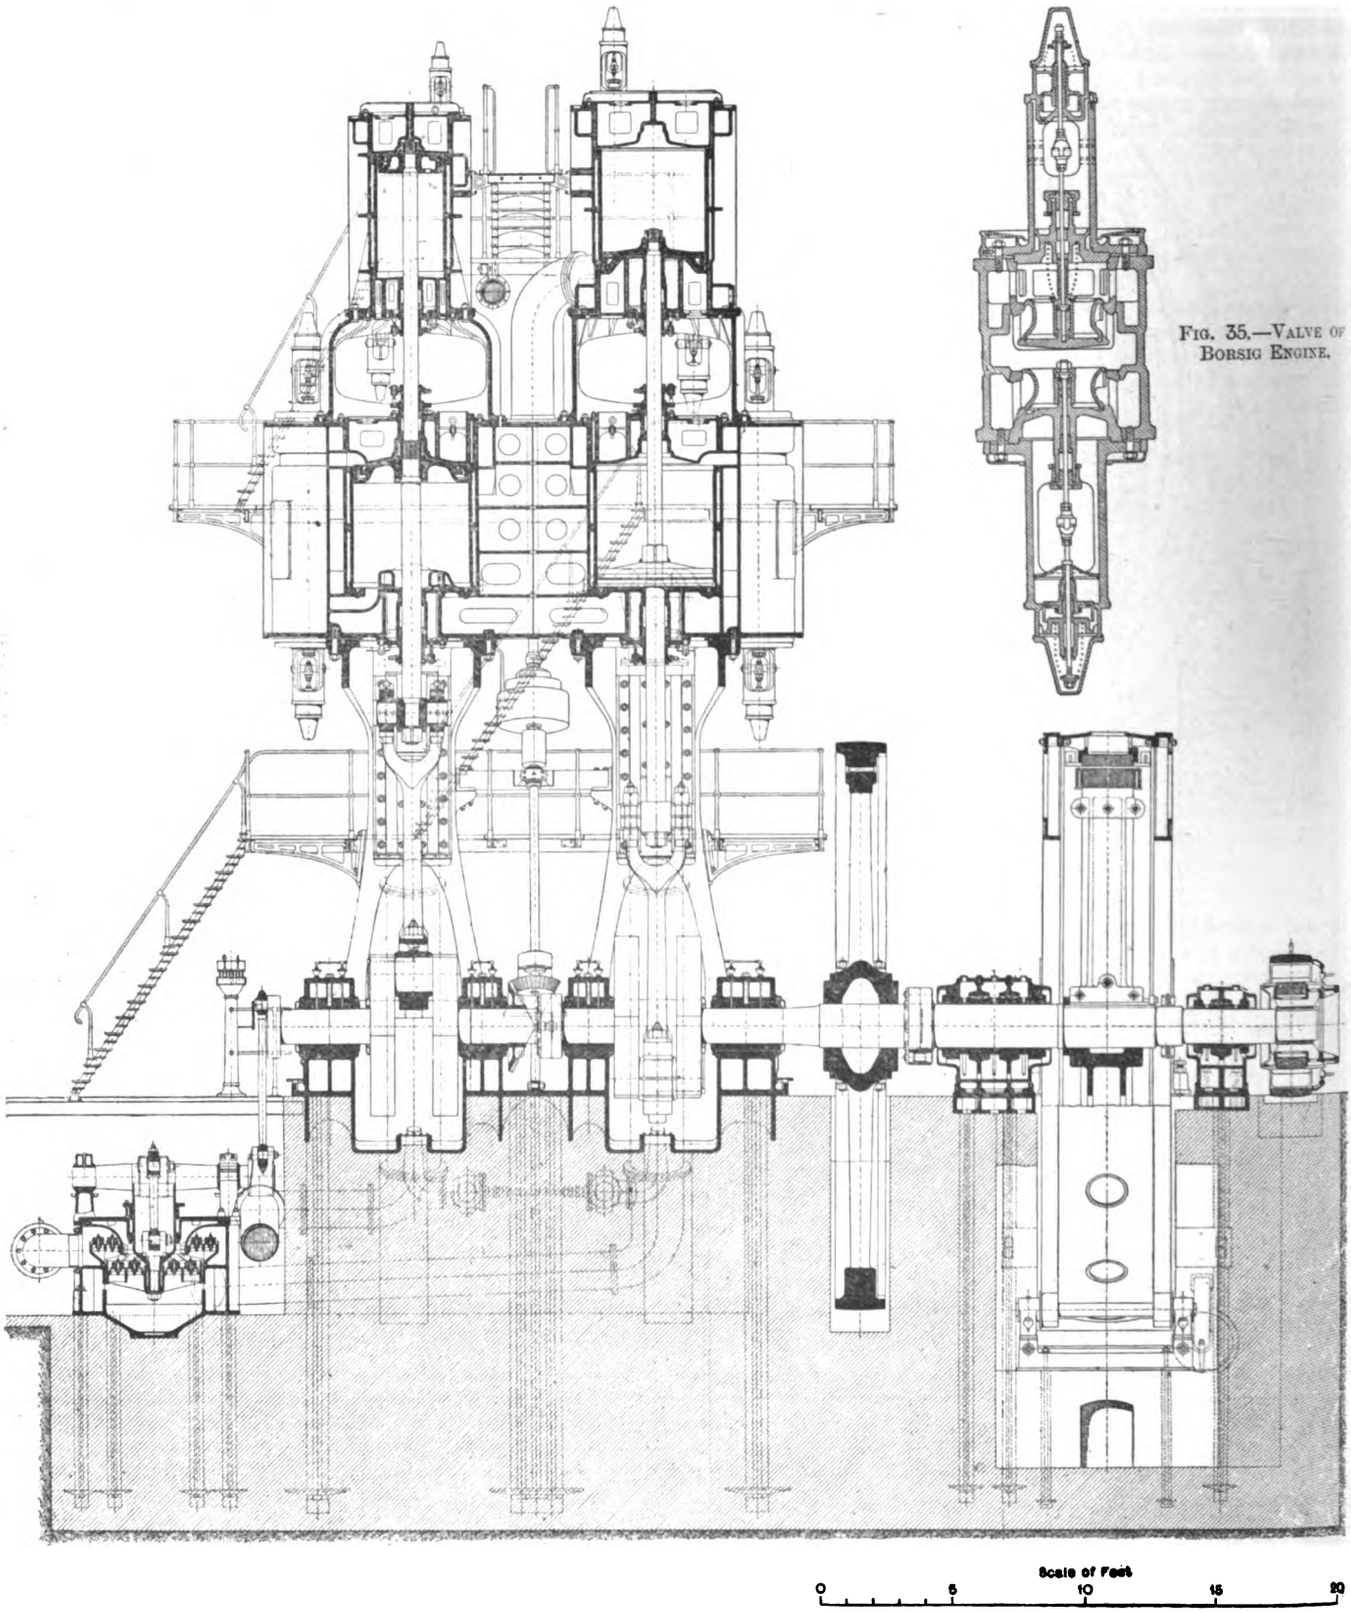

FIG. 34.—SECTIONAL ELEVATION OF BORSIG-SIEMENS 2,000KW. SET.

FIG. 35.—VALVE OF BORSIG ENGINE.

Digitized by Google

top of the engine, from which it flows down by gravity through a complete system of pipes controlled by cocks at the upper platform. At the exhibition, the engine is supplied with steam at 9·5 atmospheres pressure instead of 14, and runs at a speed of 83½ revs. instead of 90 revs. per min.

The Siemens and Halske three-phase machine is designed to generate 2,000kw. on a non-inductive load at 2,000 volts to 2,200 volts and 50 ∿ per sec. As the engine only develops 2,000 H.P. instead of 2,500 H.P. when running under

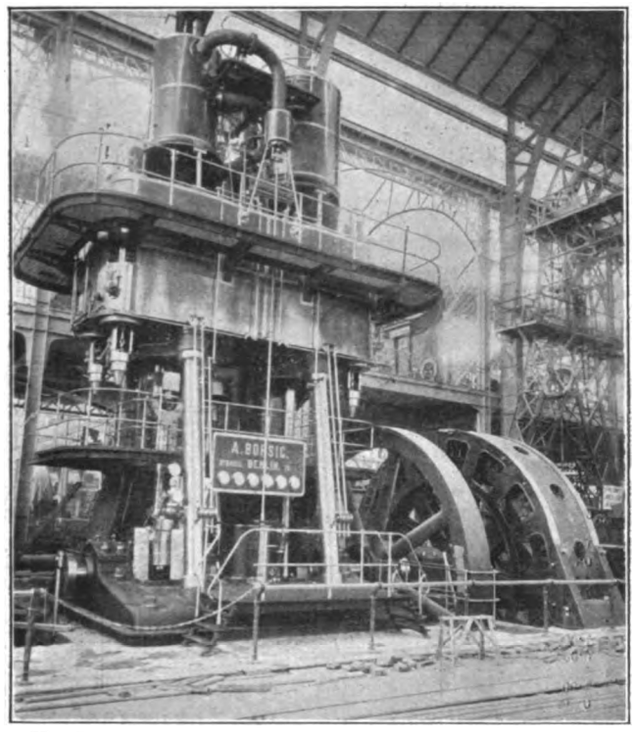

FIG. 33.—BORSIG 2,500 H.P. TRIPLE EXPANSION ENGINE, DRIVING SIEMENS AND HALSKE 2,000KW. THREE-PHASE DYNAMO.

the above conditions, the dynamo is able to supply 2,000 kilo-volt-amperes at a power factor of 0·7. The revolving field-magnet consists of a two-part cast-iron wheel, on which are 72 poles of elliptical section. The latter are laminated, the discs being held by a steel prism of square section and three bolts. The prism is threaded to take the bolts which hold the poles to the rim of the wheel. To take up the tangential stresses there is a rectangular projection from the botttom of

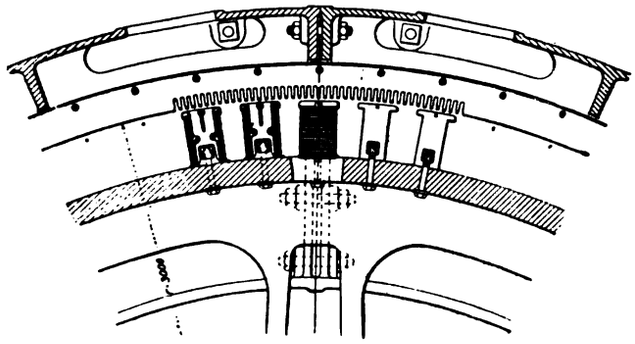

FIG. 36.—DETAILS OF MAGNETS AND ARMATURE OF SIEMENS THREE-PHASE DYNAMO.

the pole which fits into a groove in the rim of the wheel. Each pole has 40 turns of copper strip, 4mm. × 28mm. cross-section, wound on edge. At the two ends, this strip is wound on hollow bronze castings, which allow the air to pass through in a radial direction when the magnet is revolving. To assist ventilation still further a slot is cut in the middle of the pole itself. These details are seen in Fig. 36. The winding alone weighs 5 tons, and its resistance hot is about 1 ohm. A pressure of 210 volts is employed for the excitation, the mean energy required being 28kw., and the maximum 42·5kw. The exciter is a series machine generating 45kw. at 210 volts when running at the speed of the engine.

The armature of the alternator is supported between two annular castings, which are perfectly symmetrical to allow of the armature being turned for repairs. These castings are lightened by 16 holes, or each may be considered as two rings held togeher by 16 radial arms. Each is in four parts, bolted together. The armature core is made up of sheets 0·5mm. thick. The whole armature frame rests on two pairs of rollers beneath the floor, the height of each of which can be adjusted. Thus the whole frame can be lifted by raising both pairs of rollers, or by raising one and lowering the other it can be shifted sideways. Moreover, the armature can be revolved by turning the rollers. The armature casting is further secured by two floor-plates, which must, of course, be removed to turn the armature. There are 648 slots in the armature core, 13mm. wide and 55mm. deep, and the copper bar

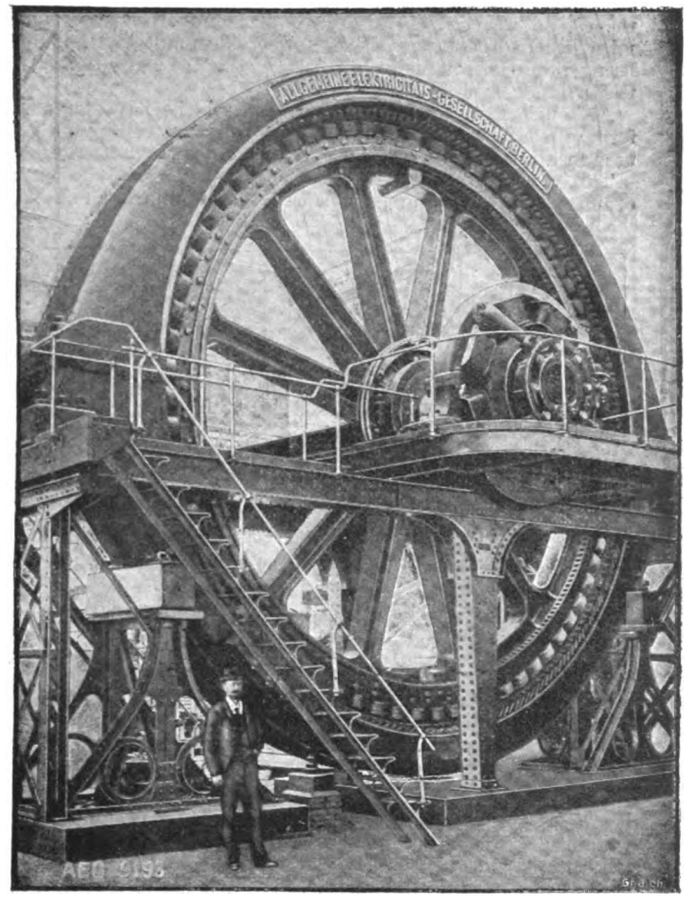

FIG. 37.—3,000KW. 3-PHASE DYNAMO EXHIBITED BY THE ALLGEMEINE ELEKTRICITÄTS GESELLSCHAFT.

windings have a section of 7mm. × 44mm. The bars are insulated with mica, which is pressed around them, and when the bar is in position the slot is closed by an insulating piece. The 216 bars joining the winding of each phase are in series, and the windings are star-connected. The weight of copper on the armature is about 2·4 tons, and its C^2R loss is about 15kw.

The enormous dynamo exhibited by the Allgemeine Electricitäts Gesellschaft in the German "annexe" (a building by itself at the Avenue de Suffren end of the electricity palace) may be mentioned here, although the machine is an exhibit pure and simple and does not generate current at the exhibition. This machine is illustrated in Fig. 37. It is designed to furnish 8,000kw. three-phase at 50 ∿ per sec. when running at 83 revs. per min., and is one of eight similar machines that are being erected in the Berlin electricity supply works. Ten others are proposed for projected extensions. Three-phase current will be distributed in some of the

Digitized by Google

suburbs, but in Berlin itself it will be converted into continuous current for the existing network. In order to show the machine in rotation at the exhibition, a small continuous current motor is coupled to it. The 72-pole flywheel field-magnet has a diameter of 7·4 metres (24ft. 3in.), and the armature frame a diameter of 8·6 metres (28ft. 9in.). It is interesting to note that the whole machine weighs 160 tons, made up as follows: Armature frame 80 tons, field-magnet 70 tons, bedplates 10 tons; and yet the whole was successfully erected without the assistance of a crane.

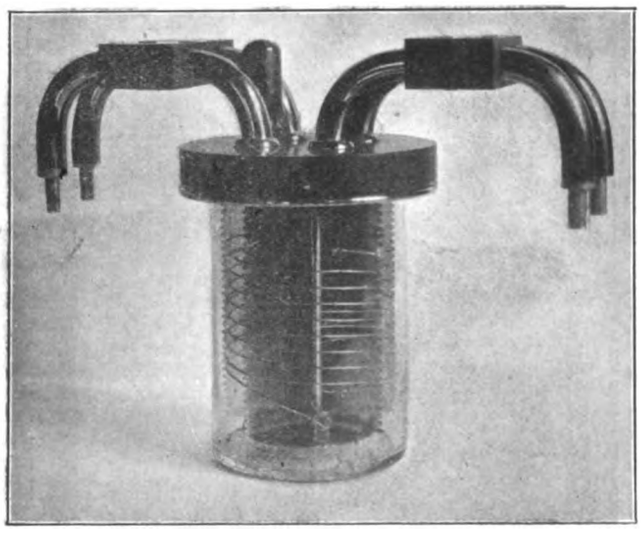
NOTE ON AN IMPROVED STANDARD RESISTANCE COIL.*

BY ROBERT S. WHIPPLE.

In June, 1896, Prof. Burstall read a Paper before the Physical Society "On the Use of Bare Wire for Resistance Coils."—*Phil. Mag.*, September, 1896 pp. 209–224—in which he described a resistance box, the coils of which consisted of bare platinum-silver wire, wound on mica frames, the frames being immersed in an oil with high insulating properties, a method of constructing the coils originally due to Mr. E. H. Griffiths, F.R.S.

Although Prof. Burstall's Paper showed the advantages of this form of resistance coil, it has not, until comparatively recently, been used for standard coils, and only in a few cases for resistance boxes.

This form of coil possesses the following advantage over the ordinary resistance coil: (1) The coils can be annealed to a dull red

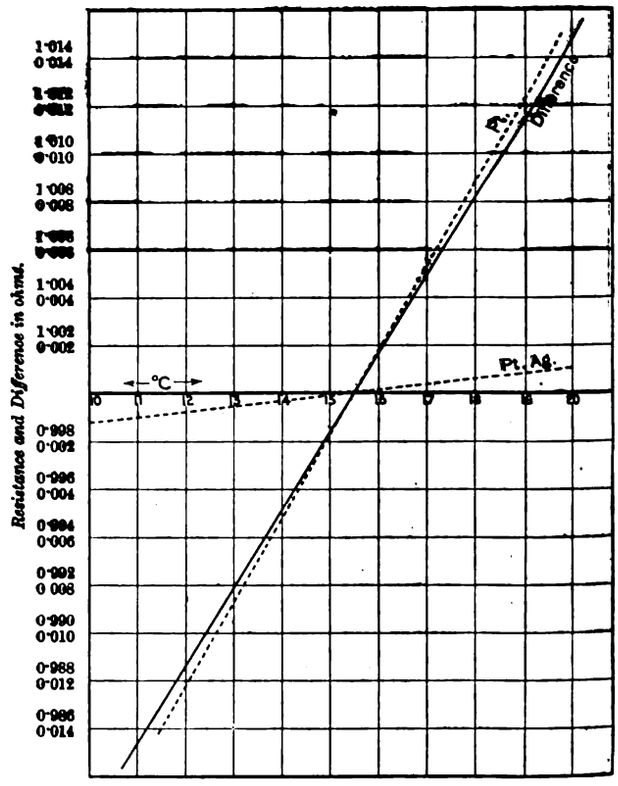


heat *in situ*, thus relieving the wire of any strain caused by the winding. (2) The heating of a wire immersed in oil is less than one silk-covered and varnished. (3) The temperature of the wire can be accurately determined by means of a thermometer placed in the oil surrounding the wire. German physicists have adopted a form of coil in which the wire is silk-covered and varnished and then placed in a metal case perforated with holes. The whole coil is placed in an oil bath when in use. This form of coil is open to the objection that it cannot be annealed above 140°C. without causing injury to the silk covering on the wire, and there is a certain amount of lag in the oil obtaining the temperature of the coil.

By request of the Electrical Standards Department of the Board of Trade the Scientific Instrument Co., Ltd., Cambridge, have designed and made two standard 1 ohm coils, the wires of which are bare and immersed in oil; a modification suggested by Mr. Horace Darwin was also fitted for obtaining the temperature of the coils. The coils proper consist of 0·035in. PtAg wire wound on mica frames, the ends of the wires being attached to stout copper terminals in the usual manner. A 0·008in. platinum wire is wound alternately with the platinum-silver wire, and is attached similarly to stout copper leads. The illustration clearly shows the method of winding. Both coils are adjusted to a resistance of 1 ohm at 15·5°C. Owing to the difference in the temperature coefficient of the two wires (PtAg 0·00024, Pt 0·00350) a small change in the temperature of the coil causes a comparatively large difference between the resistances of the two coils. This difference being known, the temperature in degrees Centigrade is given by the adjoined table. The table is calculated from the difference in the temperature coefficients of the two wires 0·00350 − 0·00024 = 0·00326 for 1°C. The table of differences, together with the values of the Pt and PtAg coils at different temperatures is also shown diagramatically:—

Temperature of Standard Coil.	Difference in resistance of the coils.	
10·0°C.	−0·01793	Platinum coil having a lower resistance than the platinum-silver coil.
11·0	0·01467	
11·9	0·01141	
13·0	0·00815	
14·0	0·00489	
15·0	−0·00163	
15·6	0·00000	
16·0	+0·00163	Platinum coil having a higher resistance than the platinum-silver coil.
17·0	0·00489	
18·0	0·00815	
19·0	0·01141	
20·0	+0·01467	

As the temperature coefficient of platinum is about 15 times as great as that of platinum-silver the resistance of this coil may be measured to one significant figure less than the standard coil without affecting the value for the temperature of this coil. In measuring small resistances the determination of the last figure to 0·00001 ohm requires considerable care, and the advantage of not being compelled to measure to such a high degree of accuracy is apparent. The two



wires being wound on the same frame alternately with each other and immersed in oil are at the same mean temperature. Any temperature gradient in the oil influences both wires similarly, thus doing away with the necessity of a stirrer. The platinum wire is also useful for testing the insulation of the windings of the PtAg coil one from the other. The coils are placed in a glass vessel in order that the behaviour of the insulating oil with time may be studied.

Coal versus Oil Fuel.—Crude petroleum oil has been used extensively in some parts of the United States as fuel for stationary boilers, and efforts have been made to introduce it generally into this country. As our readers are aware, it has already been used here in certain electric supply stations as well as on one or two locomotives on the Great Eastern Railway. A reversal of the situation, however, has taken place in Chicago where, owing to the great rise in the price of crude oil, the Chicago Union Traction Co. has been compelled to convert its originally oil-fired boiler plant to coal firing.

WIRELESS TELEPHONY.*

BY SIR WILLIAM H. PREECE, K.C.B.

The first experiments in this direction were made in the month of February, 1894, across Loch Ness, in the Highlands. On that occasion, trials were made to determine the laws governing the transmission of Morse signals by my electromagnetic method to wireless telegraphy, which has formed the subject of frequent reports to this section since 1884. Two parallel wires well earthed were taken, one on each side of the lake, and arrangements were made by means of which the wires could be systematically shortened, with a view of ascertaining the minimum length necessary to record satisfactory signals. It occurred to Mr. Gavey, who was experimenting, to compare telephonic with telegraphic signals, *i.e.*, to ascertain whether articulate speech could be maintained under the same conditions as Morse signalling. The trials showed that it was then possible to exchange speech across the loch at an average distance of 1½ miles between the parallel wires, when the length of the wires themselves was reduced to 4 miles on each side of the water. What led to this train of thought was the fact that, although the volume of a telegraphic current was immensely greater than that of a telephonic current, whenever, through want of balance in a loop, disturbance was evident, then telephonic cross talk was also manifest. In other words, a weak telephonic current was apparently as powerful a disturber as a strong telegraphic one. The sensation created in 1897 by Mr. Marconi's application of Hertzian waves distracted attention from the more practical, simpler, and older method. Mr. Evershed and Principal Oliver Lodge had in the meantime much advanced the system by introducing admirable call systems.

In 1899, I conducted some careful experiments on the Menai Straits, which determined the fact that the maximum effects are produced when the parallel wires are terminated by earth plates in the sea itself. It became quite evident that the ordinary inductive effects are much enhanced by conductive effects through the water and that in consequence shorter wires are practical. No special apparatus seems necessary. The ordinary telephonic transmitters and receivers were used. It became desirable to establish communication between the islands or rocks known as the Skerries and the mainland of Anglesey, and it was determined to do this by means of wireless telephony. The lighthouse at the Skerries was wanted to be in communication with the coast-guard station at Cemlyn, which is connected with the Post Office system. The bottom of the Channel is too rough and the currents too violent for a cable. A wire 750 yards in length was, therefore, erected along the Skerries, and on the mainland one of 3½ miles from a point opposite the Skerries to Cemlyn. Each line terminates by an earth plate in the sea. The average distance between the parallel portions of the two wires is 2·8 miles. Telephonic communication is readily maintained, and the service is a good one. Lodge's call system will be used.

Further experiments with wireless telephony have recently been made between Rathlin Island, on the north coast of Ireland, and the mainland. The east and west portion of the island of Rathlin is about 8 miles from the mainland, but a tongue of land projects southward to within a distance of 4 miles. Communication was required between the lighthouse near the north-eastern corner of the island and the mainland, and the question for solution was whether an overhead line running the whole length of the island from east to west was necessary to obtain good communication, or whether a shorter line across the neck of the southern peninsula would serve. The preliminary experiments that have been made proved conclusively that communication, both telegraphic and telephonic, has been readily maintained by means of temporary wires established across the neck of the peninsula along the shorter line. Wireless telephony across the sea is now a practical and commercial system.

No experiments have yet been made with ships, but it would appear simple to speak by telephone between ship and ship, or between ship and shore, to considerable distances across space, by means of a circuit formed of copper wire terminating at each end of the ship in the sea, passing over the topmast and using simple telephones.

* Abstract of a Paper read before Section A of the British Association at Bradford.

ON THE APPARENT EMISSION OF CATHODE RAYS FROM AN ELECTRODE AT ZERO POTENTIAL.*

BY CHARLES E. S. PHILLIPS.

It has been noticed by many people who work with X-ray or other vacuum bulbs that numerous bright green patches occasionally appear upon the inner surface of the glass walls of a bulb while a discharge is passing, especially during the process of exhaustion. These green flecks vary considerably from time to time both in shape as well as in position, and efforts have been made to connect their existence either with want of uniformity in the composition of the glass or with irregularities in the surface of the negative electrode.

I have already, in another place,* given some account of an experiment made with the object of clearing up this uncertainty, and now beg to supplement that work with the following observations as to the cause of the phenomenon. The experiment just referred to consisted in using a pivoted disc of aluminium as the negative electrode in a bulb containing rarefied air, so that when green patches appeared a rotational movement of the disc (actuated by means of an external magnet) would show whether the patches of green moved in a corresponding manner or not. It was seen that they did so move. A distinct feature of the experiment, however, consisted in ascertaining whether those flecks which persisted after the discharge had ceased were still sensitive to movements of the cathode. This also was found to be the case. The proof therefore that the green patches were associated with an emission from the cathode appeared complete. But it was further noticed that subsequent to the passage of a discharge, and even when either or both of the electrodes were connected to earth, still the green flecks were easily visible upon the glass walls of the bulb, and continued to move as before when the cathode was rotated. This was apparently a case in which cathode rays were emitted from an electrode at zero potential.

I do not know that any explanation of this effect has so far been offered, and I therefore venture to bring forward the following suggestions, supported by further experiments. When a piece of metal is placed in a rarefied atmosphere and made the negative pole for an electrical discharge passing across the attenuated gas, innumerable small bright specks of light appear over the surface of the metal. It was found convenient in my particular case to use an *iron* electrode for observations of this effect, because it had the advantage of being readily magnetisable from without. The addition of a similar iron electrode to act as the anode determined the shape of the magnetic field. With such an apparatus it could be seen that the bright spots appeared principally upon the *cathode* while the discharge passed, and that the creation of a magnetic field between the electrodes made visible the individual luminous streams of gas emanating from those tiny points of light. The paths of these luminous streams, becoming bent by the action of the magnetic field, followed the direction of the lines of magnetic force and exhibited a tendency to become spiral in accordance with well-known laws. In this way a fine layer of sodium upon the anode was caused to fluoresce through the action of the negatively electrified particles beating down upon it. One was able, in fact, by this means to cast shadows of objects placed in the paths of the bent streams, and at a pressure considerably higher than that necessary for the production of the well-known cathode shadow effects. In the above case, however, the method served to clearly establish the fact that the bright points of light upon the surface of the cathode indicated the places from which the jets of gas originated. The number of these jets became less as the exhaustion was continued, and individual streams were very clearly seen owing to the action of the magnetic field. When the discharge began to cause fluorescence in the glass of the bulb some green patches made their appearance, and, in some cases, when the cathode was magnetised a bright spot, which was previously judged to indicate the origin of a green patch upon the glass, would shift to a new position upon the electrode. In all such cases the corresponding patch also moved in a similar manner upon the glass. At sufficiently high exhaustions the bright spots upon the electrode disappeared entirely, although green flecks were still visible upon the glass. But a movement as before of the electrode as well as its magnetisation gave results consistent with previous observations. Under these conditions, when the discharge through the bulb was stopped, green flecks were still visible for about ten seconds. A positively-charged body was brought up to the outside of the bulb and the patches brightened considerably. A negative charge similarly placed extinguished the flecks completely. This was also the case when the electrodes were connected to earth. Finally, vacuum bulbs, such as X-ray lamps, &c., exhibiting green flecks while in operation, were generally found to deteriorate if laid aside for a month or two, owing to an increase in the pressure of the contained gas. We see therefore that, in the first place, the bright points of light upon the surface of the cathode are due to the emission of fine jets of gas; also that such jets, if negatively charged, may be made to cast shadows of objects suitably placed in their paths. It is at the same time clear that the green flecks referred to above are due, during the passage of a discharge, to these same jets of gas impinging upon the inner side of the glass walls, and that, under the conditions existing immediately subsequent to the passage of the discharge, it is evident that streams of gas continue to be emitted from the pores of the electrodes. In spite of the fact that with the electrodes connected to earth these streams consist of unelectrified particles, they assume that property of ionisation during their passage across the space within the bulb which appears to be essential to the production of local fluorescence in the glass upon which they impinge.

* *The Electrician*, Vol. XLI., 1898, pp. 425-426.

Digitized by Google

This latter effect, while explaining the process by which a cathode emission may appear to originate at an electrode with no electrical charge upon it, is one to which I wish to draw especial attention, for there is reason to believe that the upper limit of speed for the individual particles constituting the jets cannot exceed the rate at which sound is propagated. It is therefore interesting to find that, under such circumstances, fluorescence was produced in the glass upon which the streams impinged. As many of the observations referred to here were made during the course of an investigation into the dis-electrifying action of magnetism now being carried out by myself at the Davy-Faraday Laboratory of the Royal Institution, I desire to express my indebtedness to the managers of that institution for the facilities which they have kindly placed at my disposal.

ON THE SIMILARITY OF EFFECT OF ELECTRICAL STIMULUS ON INORGANIC AND LIVING SUBSTANCES.*

BY PROF. J. CHUNDER BOSE, D.SC.

Molecular Change Produced by Electric Stimulus.

Effect on Muscles.—If we take a piece of living tissue, say a piece of muscle, and subject it to an electric stimulus, there will be produced a contraction; the stimulus causes a re-arrangement of the particles of the living substance by which the form of muscle is changed. On the cessation of stimulus, the muscle recovering from the strain gradually attains its original shape.

Effect on Nerves.—The effect of stimulus on nerves is not apparent; there is no change of form. The molecular disturbance due to stimulus can, however, be detected in an indirect manner from certain electromotive variations that are produced.

Effect on Inorganic Substances.—If we take, for example, a mass of metallic filings and subject them to electric shocks, there is found to be no visible change. The substance appears to be irresponsive or dead to stimulus. Are inorganic substances then really irresponsive? Could this apparent want of response not be due, after all, to our inability to detect the profound molecular changes that may have, nevertheless, taken place in the substance under the action of stimulus? In nerves the molecular changes could only be detected indirectly by an electric method. I shall describe in detail an electric method which will tell us whether, after all, a stimulus does evoke a moleculr thrill even in inorganic substances. First of all let us study the effect of the very quick electric vibration known as light on inorganic matter. If we take a piece of yellow phosphorus and subject it to light, it will be found to be slowly converted into the allotropic red variety; the substance will be strained from one molecular condition to another. But for the fortunate circumstance of the change of colour we could not have detected by sight the change produced. Even if there had been no visible change, we could have still detected the molecular change due to radiation by means of other methods; for it is obvious that any molecular change in a substance must be attended with corresponding physico-chemical changes. In the case of the red variety of phosphorus, in comparison with the yellow variety, it is found to be chemically less active, insoluble in CS_2 and of higher specific gravity. We may also expect its other properties such as elasticity, its position in the voltaic series, its electric conductivity, &c., to be similarly modified. As a matter of fact the conductivity of red phosphorus is greater than that of the yellow variety. We may thus detect the variation produced in the molecular arrangement by measuring the corresponding variation of any of the above properties. The choice of any particular method is one of convenience and of special applicability under the given conditions. I have shown in my Paper "On Electric Touch and the Molecular Changes Produced in Matter by the Action of Electric Waves," *Proc.* Roy. Soc., February, 1900, that the conductivity method of detecting molecular strain is one of very great delicacy; this is the method which will be constantly referred to in the present Paper. Occasional reference will also be made to the electromotive variation method, which will be described in detail on a future occasion.

Conductivity Method of Detecting Molecular Strain.

In the case of phosphorus it would be possible to detect the molecular change due to radiation by interposing it in an electric circuit containing a galvanometer. As the yellow phosphorus is gradually converted into the red variety, on account of the increased conductivity of the latter, there would be produced a corresponding increase in the galvanometer deflection; the increased deflection will thus be a measure of the molecular change produced by radiation. For the most sensitive arrangement a solid lump of the substance is not suitable; the molecular change would then be confined to the thin layer on the surface, the mass in the interior remaining unaffected. For increased action the substance should be spread out in the form of a thin layer of particles accessible to the radiation. This is one of the reasons why it is better to have the substance in the form of powder if the molecular change is to be detected by the conductivity method. There are other additional reasons which will be presently given.

Molecular Change produced by Electric Radiation.—Let us now take a mass of metallic filings interposed in an electric circuit and subject it to the stimulus of much slower electric radiation. As in the last case, the molecular change produced by radiation will be detected by the change of conductivity produced.

Theory of Coherence.—A tube containing a mass of metallic filings is thus a good detector of electric radiation, and is sometimes called a coherer. For reasons given below it is preferable to call such a detector a "molecular receiver." Filings of a number of metals were found to exhibit a diminution of resistance under electric radiation, and this diminution was found to persist until the particles were "decohered" by tapping. Prof. Lodge was thus led to suppose that the effect was produced by minute induction sparks, due to electric radiation, welding the particles together. The theory of coherence leads to the conclusion that *all* sensitive substances should exhibit a diminution of resistance; in other words, the action should be non-discriminative; it also follows from the same theory that there should be no self-recovery.

Theory of Molecular Strain.—But in carrying out a systematic investigation on the action of electric waves on fragments of elementary substances I found that while some substances—*e.g.*, Mg, Fe, Bi, exhibit an increase of conductivity or a positive effect, others—*e.g.*, K, As, I, exhibit a diminution of conductivity or a negative effect; and, further, the effect, positive or negative, is found to be a periodic function of the atomic weight of the substance. This at once shows that the action is one of atoms or of molecules. I have also found that in many cases the change of conductivity is not permanent, but the substance quickly recovers and attains its original conductivity on the cessation of radiation stimulus, as if a force of restitution was called forth to restore the substance to its equilibrium position of original conductivity.

Imagine a small magnetometer needle (with the usual arrangement of mirror and reflected spot of light) suspended by means of a thin wire, and imagine the earth's field neutralised by a controlling magnet. When a second magnet is approached "end on" there would be produced a distorting couple which would twist the wire, the torsion of the wire balancing the magnetic force. This distortion of the wire is measured by the deflection of the spot of light. As the distorting force is increased by the gradual approach of the magnet, there is produced a corresponding increase of distortion as seen in the increased deflection of the spot of light. If the magnet is now removed, the wire will recover from distortion (with the return of light spot to the original equilibrium position); the wire will recover quickly if made of highly elastic steel, slowly if made of viscous lead. I will now describe a parallel experiment, where the radiation-stress produces a molecular strain attended by a corresponding variation of conductivity of the substance, the conductive distortion being measured by the galvanometer deflection.

Proof of Radiation producing Molecular Strain.—I have found that the bromides of several metals exhibit a distortion of conductivity (a diminution of conductivity) under electric radiation, and that on the cessation of radiation the recovery is very quick. Let a small quantity of lead bromide in the form of powder be interposed in an electric circuit, and the pressure on the powder and the E.M.F. properly adjusted till a suitable deflection, which I shall call the normal deflection, is obtained in the galvanometer. The resistance of the galvanometer and the voltaic cell being relatively small in comparison with the resistance of the sensitive powder, the above *normal* deflection represents the conductivity of the substance under the given conditions; the deflection will remain constant as long as the substance is left undisturbed. But any external stimulus producing molecular distortion will be detected and measured by the corresponding *variation* of deflection produced in the galvanometer, just as the distorting magnetic force was measured by the variation of the magnetometer readings.

I now placed an electric radiator at a distance of 125cm. from the "molecular receiver" of lead bromide; the radiation stimulus at once produced a diminution of conductivity, the *normal* deflection being reduced by 44 divisions. If the radiator is now removed, the normal conductivity is at once restored, the deflection attaining its original value. It is thus seen that no permanent change of conductivity is produced, the force of restitution merely balances the distorting force due to radiation. If there is any fluctuation of radiation intensity, there would be produced a corresponding variation of conductivity-strain in the substance. As a matter of fact, it is difficult to keep the intensity of radiation uniform; there is a flicker, and in the experiment just described there is a slight fluctua-

* Paper read before Section A of the British Association at Bradford.

Digitized by Google

tion in the deflected spot of light. On the gradual approach of the radiator there was a corresponding increase of deviation. Thus :—

Distance of radiator.	Deviation.
125cm.	44 divisions
100cm.	63 do.
75cm.	74 do.
50cm.	110 do.

Just as the quickness of recovery of a twisted wire depends on its elasticity, so also the rapidity of recovery from the state of conductivity strain is determined by the electric elasticity of the substance. The recovery is, for example, very quick with potassium and slow with magnesium.

On the theory of coherence the above results are without any meaning and absolutely inexplicable. On the theory of strain, the meaning is quite obvious.

Further Proofs.—If the effect of electric radiation on a substance is one of strain, then it follows : (1) That the substance will recover from the strained condition due to radiation, provided the resulting strain is within the limit of the elasticity of the substance ; hence the substance will exhibit self-recovery (*a*) if the stimulus is not excessive, or (*b*) if the electric elasticity of the substance is very great. I find that on careful adjustment a receiver often exhibits self-recovery when the intensity of the incident radiation is feeble. I also find that substances which are, electrically speaking, highly elastic (*e.g.*, potassium), exhibit an automatic recovery even when the stimulus is very strong. (2) But if the substance has a narrow elastic limit and the stimulus is too great, then there would be produced a more or less permanent distortion. This molecular distortion will be attended with a more or less permanent charge of conductivity. In the case just described, owing to molecular friction, the recovery of the substance when left to itself will be very slow. The substance being distorted to the maximum extent will exhibit little sign of response to the further action of stimulus ; the absence of response or "fatigue" is thus due to the overstrained condition of the substance. (3) For the reasons given above, the recovery

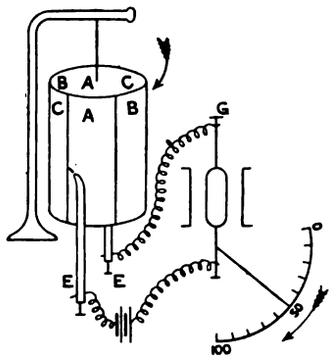

FIG. 1.—Diagram of the Electric Circuit containing the Sensitive Substance.

of a substance from the strained condition should be hastened by molecular vibration. A fatigued receiver should thus be re-sensitised by molecular vibration due either to tapping or to a gentle application of heat. These conclusions are borne out by experiments. (4) The recovery of the substance, either (*a*) slowly, or (*b*) in a "dead beat" manner, or (*c*) after one or more vibrations, will be determined by the viscosity of the substance. In working with sensitive receivers made of various substances, I have obtained indications of the above types. It will thus be seen that the above theoretical deductions, based on the theory of molecular strain, are in all cases experimentally verified.

It is often forgotten that the conductivity of a substance does not simply depend on the chemical nature of the substance. The state of molecular aggregation also plays an important part in determining the conductivity of a substance, and as an illustration we may take the case of carbon, which exhibits wide differences of conductivity in the two allotropic states of graphite and diamond. Imagine a piece of carbon in an intermediate or neutral state between graphite and diamond. Suppose an external force distorts it to a small extent towards the more conducting graphite state. This distortion would be attended with an increase of conductivity from which latter the extent of distortion may be inferred. Now, during the distortion from equilibrium position, a force of restitution will tend to restore the substance to its original neutral condition. If the distortion does not proceed beyond the elastic limit, then, on the cessation of the distorting force, the substance will recover its original state, and this will be evidenced by the restoration of its original conductivity. But if the distortion is of a sub-permanent type, then mechanical vibration or heat will hasten the recovery of the substance to its original condition.

The permanent distortion known as allotropic transformation due to luminous radiation is seen in the production of red phosphorus from the yellow variety and the insoluble from the soluble variety of sulphur.

A substance responds to an external stimulus as long as there is a certain amount of mobility of its molecules. I will, in a future Paper, show that a selenium cell acts in the same way as the molecular receivers described above—that is to say, a molecular strain is produced in it by the stimulus of light. In order to make the selenium cell sensitive, a careful process of annealing is found necessary. The cell ceases to respond or is "killed" when there is a permanent set in its molecules.

A Mechanical Model.—It has been said before that the conductive aspect of a given substance is not definite but variable, the conductivity being dependent on the particular molecular condition of the substance. This peculiarity may be represented in the accompanying model, if we give to the cylinder representing the sensitive substance, three main conducting aspects ABC. The non-conducting aspect is represented by C. With the sensitive substance in this particular condition interposed in an electric circuit, the current in the galvanometer would be zero ; A is the semi-conducting aspect of the substance, and let the corresponding galvanometer deflection be 50 ; B is the highly-conducting aspect, the corresponding galvanometer reading being 100.

The cylindrical piece ABC representing the sensitive substance is divided along the circumference into six parts, the opposite sextants being put in electric communication. The opposite sextants CC are coated with shellac to represent the non-conducting aspect ; the sextants AA are coated with graphite to represent semi-conducting aspect ; and the highly conducting aspect is represented by the sextants BB coated with tinfoil. The three main aspects of the sensitive substance are thus represented in the model ; it is to be understood that with sensitive substances under the action of radiation, the transition from one aspect to the next is gradual and not abrupt, as represented. The sensitive substance is interposed between the two electrodes EE ; the torsion of the suspending wire represents the force of restitution. G is the suspended coil of a D'Arsonval galvanometer in circuit, which by its deflections exhibits indirectly the molecular strain produced in the substance by radiation.

Suppose we start with the substance in its normal state A, with moderate conductivity, and let the corresponding galvanometer deflection be 50 ; let the substance belong to the positive class which exhibits an increase of conductivity under radiation. The radiation stimulus will, therefore, distort the substance to a state of increased conductivity, the increased conductive aspect B being brought opposite the electrodes EE ; the increased current thereby produced causes a deflection of, say, 100 in the galvanometer. If the strain has not been excessive the substance will return to its original position of equilibrium on the cessation of radiation stress, and the galvanometer deflection will fall from 100 to the original value, 50. If the substance belongs to the negative class the distortion will be in the opposite direction, and the effect of stimulus will be a diminution of conductivity.

Method of obtaining Curve of Molecular Response.—The suspended coil of the galvanometer thus moves in perfect response to the varying strain produced in the sensitive substance by the action of stimulus. The invisible molecular distortions are thus revealed by the visible deflections of the galvanometer coil ; the effect on one is merely the reflection of the effect on the other. Curves of molecular effect due to the action of radiation may thus be obtained with the galvanometer deflections as ordinates and the time of exposure (or the time of recovery) as abscissæ. It is thus seen that these curves faithfully represent the invisible molecular strain effect due to the stimulus and the after recovery from the strain.

The Muscle Curve and the Molecular Response Curve.—When a muscle is stimulated there is produced in it a re-arrangement of its particles ; this is attended by a shortening of the muscle. A muscle curve is a graphic record of the contraction due to stimulus and the gradual recovery from the strain after the cessation of the stimulus. A muscle curve thus records the history of the strain effect produced by a stimulus in a living tissue, just as the molecular response curve records a similar effect in an inorganic substance. The two represent the same thing ; in one the strain is detected by the change of conductivity, in the other the same strain is detected by the change of form. We have thus means of studying the molecular response produced in both the inorganic and living substances by electric stimuli of varying frequency, intensity and duration.

In the above are included some of the most difficult problems that underlie both physics and physiology. The subject is very extensive, and our knowledge proportionately inadequate. Very little is definitely known about the influence of ether disturbance on matter. A great gulf separates the phenomena of the living from those of the non-living. But if we are ever to understand the hidden mechanics of the animal machine, attempts have to be made to solve these problems, and many difficulties have to be faced which now appear very formidable.

Before taking up the comparative study of the effect of electric stimulus on inorganic and living substances, I will say a few words about the continuity of certain phenomena.

Effect of Electric Vibration on Discontinuous Particles and on Continuous Solids.—The variation of conductivity due to electric radiation is very great in discontinuous particles, but is supposed to be wanting in continuous solids. This is not altogether correct, for I have detected such a variation even in a continuous solid, though the variation is small. The following are the probable reasons for the feebleness of action in the latter, specially when the effect is measured by the variation of conductivity method: (*a*) The action of quick electric oscillation on molecules of the solid is only skin deep; the effect cannot pass to any depth. As the action is one of surface, the larger the surface the greater is the effect produced. We see that in loose particles the effective surface is very much enlarged. Again, any effect on the numerous surfaces (which also form points of electric contact for the conduction of current) greatly affects the conduction. When the particles become continuous, the radiation can only affect the layer of molecules on the surface, the inner layers being protected by the outer conducting sheet. The molecular changes produced on the comparatively thin layer on the surface do not affect to any great extent the conductivity of the continuous particles in the interior of the solid. I have, however, succeeded in detecting this skin-effect by the variation of electromotive variation. (*b*) In order that the molecules may undergo a change of aggregation, it is necessary that there should be a certain amount of freedom of movement. The strain effect would take place more easily on the surface than in the constrained position inside a solid mass. (*c*) In addition to the above there is another phenomenon to which the observed feebleness of effect may also be due. I find that the effect feeble radiation is often, if not always, opposite to the action of strong radiation. Thus with the positive class of substances, the effect of strong radiation is produce a *diminution* of resistance. But if the intensity of radiation is decreased till it falls below a critical value, then the effect of the feeble radiation will produce an *increase* of resistance. There is thus produced a sort of polarised action, a positive action on the portion of a sensitive substance on which strong radiation acts, and a negative reaction on another portion of the sensitive substance where the intensity of incident radiation is feeble. Now, in a continuous solid the intensity of radiation will get gradually diminished (by absorption) as it passes inwards, and thus the intensity in the interior soon falls below the critical value. The resultant effect will thus be due to the *difference* of opposite effects on the outer and inner layer of the solid. I have obtained several results in support of this view, and these considerations offer a satisfactory explanation of some obscure reversal effects in certain phenomena of vision.

Continuity of Effect of Electric Vibration of Widely Varying Frequencies.—References have already been made of the molecular change produced by the high-frequency electric vibration of light. It has also been shown how the low-pitched electric radiation produces similar action on metallic particles. Similar molecular change (attended with a variation of conductivity) is also produced by a single electric shock. A variation of current or of E.M.F. produces similar effect. (There is a critical E.M.F. which I find necessary to produce the above change.) It will thus be seen how essentially continuous is the effect of electric stimulus of varying frequencies on matter. I need only add that in considering the effect of electric vibration on matter, the modifying influence of selective absorption should also be borne in mind.

Continuity of Effect on Elementary Substances and on Compounds.—I have found that the molecular effect due to electric stimulus is not only produced (1) in all elementary substances—metals, non-metals and metalloids, but also (2) in metallic compounds, such as the various chlorides, bromides, iodides, oxides and sulphides. There is thus seen a continuity of effect of electric stimulus on different forms of inorganic matter. I will now proceed on the comparative study of the direct and after effect of electric stimulus of (*a*) varying intensity and (*b*) duration on inorganic matter and on living tissues. I have already explained how the response curve for inorganic substances may be obtained with the variation of conductivity (as inferred from galvanometer deflections) as ordinates, and the time as abscissæ. These curves will be compared with the corresponding curves for muscles, as given in well-known text-books on physiology.

On the Comparative Study of the Molecular Response Curve of Inorganic and Living Substances.

Under the subsection (*a*) I will describe the effect of a given stimulus on inorganic substances, and under (*b*) the effect of a similar stimulus on muscles.

1. *Moderate Distortion.*—(*a*) Curve for slightly warmed magnetic oxide of iron. As an instructive example representing the general effect produced by electric stimulus on inorganic substances, I will give a detailed account of the curve for Fe_3O_4. The curves of various inorganic substances differ from each other only in the rapidity of recovery from the effect of stimulus. The specific difference between the positive and negative classes of substance should, however, be borne in mind: in the former the stimulus produces a diminution and in the latter an increase of resistance. The curves for the two classes will still be comparable if the ordinates in the one represent the conductivity and those in the other the resistivity. The advantages of magnetic oxide of iron are (1) that owing to its chemical stability there is no secondary chemical action, (2) that when kept slightly warmed it exhibits self-recovery, and (3) that the direct and after effects of stimulus are not too quick for detailed observation

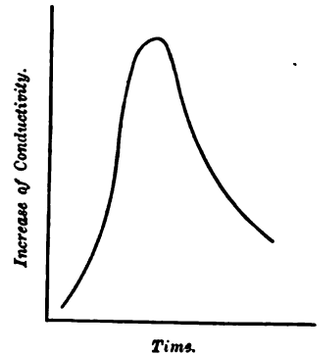

Fig. 2.—Curve for Fe_3O_4.

and study. With this substance it is quite easy to take time observations and obtain quantitative readings from which the curves are easily obtained. The curve given in Fig. 2 represents the effect of a stimulus of short duration (due to an instantaneous flash of electric radiation).

There is a latent period. The response begins to take place a very short time after the action of the stimulus, the molecular effect continues even after the cessation of the stimulus; it attains a maximum, after which the substance recovers with more or less rapidity.

Fig. 3.—The Muscle Curve.

The recovery is rather slow with many substances, but with magnetic oxide of iron the recovery is fairly rapid when the temperature is moderately warm (see below); it is also very rapid at ordinary temperatures with potassium and the bromides of several metals. With certain sensitive substances I have also noticed a tendency to an oscillation or after-vibration. The molecular effect described above is also produced when platinum or any other noble metal is taken as the sensitive substance. This shows that the effect of stimulus does not give rise to any chemical action; the *primary*

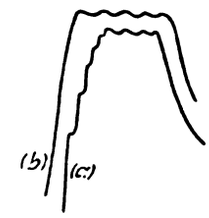

Fig. 4.—Superposition of Effects: (*a*) Effect due to Slow Intermittence. (*b*) Tetanic Effect due to High Frequency Intermittence.

effect is one of molecular strain—the strain which gives rise to the allotropic modification of a substance. If the substance is kept immersed in a medium with which the strained substance can enter into a chemical reaction, it may do so; but such effects are secondary. This aspect of the subject I will treat in detail in a future Paper, "On the Theory of Photographic Action."

(*b*) Muscle curve. In Fig. 3 is given the usual curve for muscles, which will be found to be very similar to the Fe_3O_4 curve given above. There is a phase (1) of a latent period, then (2) a

Digitized by Google

phase of increasing action *bd*, and (3) a phase of return to the original condition. Just as in the curve with inorganic substances, the recovery may be either slow or quick, depending on various circumstances. In the muscle curve there is also a very interesting fourth phase known as "Elastic after-vibration." There seems to be some differences of opinion among physiologists as regards the reality of this fourth phase. From some of my experiments, which will be given later on, it would appear that in the retina, at all events, there is an oscillatory after-effect.

2. *Superposition of Stimuli.*—(*a*) As the magnetic oxide of iron when slightly warmed exhibits self-recovery, I tried experiments to find out the effect of superposition of stimuli. Three sets of experiments were carried out—(1) on the effect of the superposition of maximum stimuli; (2) on the summation effects of medium stimuli with slow intermittence; and (3) the summation effect with rapid intermittence. (1) Maximum stimulus: By bringing the radiator sufficiently near a maximum effect was produced on the sensitive substance. The maximum deflection was thus found to be 230 divisions. Before the substance could recover to any extent a second flash of radiation was superposed. This produced no further deflection. But if the second stimulus is applied after recovery, then the second deflection is the same as the first—*i.e.*, 230 divisions. (2) Medium stimulus, slow intermittence: In this set of experiments the radiator was moved farther away, so that the intensity of the stimulus was moderate. The successive flashes of radiation were given out at intervals of 2sec.; the approximate increase of deflection due to the effects of successive flashes (1), (2), (3), &c., are given below :—

	Deflection.		Deflection.		Deflection.
(1)	100	(4)	15	(7)	2
(2)	30	(5)	6	(8)	-2
(3)	20	(6)	4	(9)	3

The self-recovery being not very rapid, the fall during the intervals of 2 sec. was very slight. After the sixth flash the further rise was small; after this there were only slight fluctuations. On the cessation of radiation, the substance gradually recovered. It will be noticed that whereas the successive distorting forces were equal, the corresponding strain effects are less and less, as may be seen in the gradual shortening of the height of the succeeding steps (see Fig. 4 (*a*)). The elasticity undergoes a rapid increase with the increased strain. After the maximum effect has been produced by the summation of stimuli, there is but little further action. The effect is not unlike the successive diminished compressions produced in a spiral spring by the successive additions of equal loads. Again, if a piece of muscle is stretched by a weight, and the stretching force is continuously increased by equal increments, the corresponding elongations are not uniform; the elasticity is found to increase with the increased strain.

3. *Rapid Intermittence.*—When the stimuli follow each other with great rapidity, the intermittent effects are fused together; the rising curve is found to be unbroken, and the effect may be described as "tetanic" (see Fig. 4 (*b*)). When the maximum effect is produced, the force of restitution is very great, and this is just balanced by the radiation stress. In this part of the curve representing a state of rather unstable equilibrium, any fluctuations of either force will be attended with a corresponding fluctuation; as a matter of fact there is a slight fluctuation in this part of the curve. On the cessation of radiation, the elastic rebound being strong, the recovery is rapid and the fall curve very steep, specially in the first part. This is found to be the case only after the maximum strain, but when the strain is moderate, the recovery is comparatively slow, and the slope of fall curve gentle.

(*b*) The curves for muscles under the above conditions are simply the reproductions of those given above. The various effects produced on muscles under intermittent stimulation are absolutely identical with those on the inorganic substance Fe_3O_4. In muscles, too (1) with maximum stimulus, the second stimulus has no further effect on the maximum contraction due to the first; (2) with the moderate stimulus, there is a summation of effect; if the intermittence is slow, the individual effects can be made out (see Fig. 4 (*a*)); (3) with very rapid succession of stimuli there is a fusion of effect known as tetanus (see Fig. 4 (*b*)).

4. *Opposite Effects due to Strong and Feeble Stimulus.*—With many inorganic substances, I found, as previously mentioned, that if a moderately strong intensity of stimulus produces a certain normal or positive effect, then a feeble intensity would produce a negative effect; in other words the effects of the stimulus above and below the critical intensity are opposite. Though this is very curious, yet it is not singular, for we know of other molecular effects whose sign is reversed when the intensity of the force acting exceeds a certain critical value. I believe a similar effect has also been observed in the physiological action of drugs, which act as chemical stimuli, a small "dose" being found to give rise to an effect precisely opposite to that produced by a large dose.

(*To be continued.*)

THE PRODUCTION OF AN ARTIFICIAL LIGHT OF THE SAME CHARACTER AS DAYLIGHT.*

BY A. DUFTON, M.A., B.SC., AND W. M. GARDNER.

It is a matter of common experience that many colours alter in appearance when seen by artificial light. The extent to which colours may vary under different illumination is perhaps not commonly known, but is well illustrated by the range of dyed cloths exhibited. Amongst other patterns, one which is green by daylight becomes red-brown by gaslight; a violet changes to purple; a grey to heliotrope; a shade of tan to a brick red. Particularly striking is a pattern woven from specially dyed yarns, which appears a uniform green colour by daylight, but which is figured by gaslight. Seen by the light of the electric arc, the patterns show similar but less marked changes. It may be of interest to indicate briefly how such peculiar changes of colour arise. The colour of a body depends in the first place on the nature of the incident light. In monochromatic red light a red appears much the same as in daylight, but a yellow changes to red, a green is almost black, while blues and violets become red. Gaslight shows a continuous spectrum from red to violet, but compared to daylight is of a strong orange colour due to an excess of rays in the red, orange, and yellow. It does not, however, necessarily result that all colours appear redder by gaslight. It is, indeed, well known that the majority of colours change little by gaslight. This is due to the adaptability of the eye; if the light becomes redder the eye becomes less sensitive to red; if the light is deficient in green, the eye becomes more sensitive to green. Persons working by gaslight soon cease to notice its intense orange colour. It results that a grey produced by mixture of black and white appears grey under any illumination, and simple colours, such as reds, oranges, and some greens, giving light confined practically to one part of the spectrum, undergo little change.

Generally, however, the colour of a body is due to a mixture of light from different parts of the spectrum. All violet colours are transparent, not only for violet, but also for blue and red light; all blues transmit not only blue, violet, and green light, but also more or less red. Consequently, whenever a blue or violet is used in the production of what is called by artists a "tertiary" colour, the general result is a colour having bright bands in different parts of the spectrum. A mixture of red, blue, and yellow to produce a neutral grey will show bright bands in the red and green—complementary colours, resulting in a proportion of white light. According to the exact position and intensity of these bands the grey will become redder or greener or may even remain unchanged by gaslight. Generally, colours become redder under artificial light. This is due not merely to the redder character of artificial lights as compared with daylight, but to the peculiar transparency of colouring matters for red light. Among reds and yellow we have many theoretically perfect colouring matters—a perfect yellow being one having sharp absorption in the violet and blue, and perfect transparency for green, yellow, orange and red rays. A perfect blue would be transparent for violet, blue and green, and opaque for the rest of the spectrum. Apparently such a blue can only be obtained by means of cupric salts. All other blue dyes and pigments we have examined agree in being more or less transparent for red light. Even greens transmit some red. This peculiar transparency of colours for red light is of primary importance in colour matching. All dyers know how persistent is the tendency to the development of red in the production of compound shades.

The need of an artificial light which should so closely resemble daylight as to show colours in their true relationship has long been felt by workers in colour. At present the electric arc light is largely used for colour work, but, as we have seen, it is far from satisfactory. The peculiar character of daylight is due essentially to the modification produced by the atmosphere in the light from the sun. Light from a north sky as usually adopted for colour work is deficient in red, orange, and yellow rays, and consequently the light from a clear north sky is intensely blue.

Starting with the electric arc light as being nearest daylight in character, we have attempted to imitate by direct absorption the effect produced by scattering in the atmosphere. The light of an arc lamp consists of two distinct parts: (1) The light from the glowing carbons; (2) the light of the arc itself, characterised by its richness in violet rays. In lamps of the enclosed arc type the length of arc is increased, and consequently such lamps give a light richer in violet rays. Although arc lights vary somewhat in the proportion of violet light, they all agree in being richer than daylight in the amount of red, orange, and yellow rays, compared with the amount of green and blue. Owing to the peculiar transparency of colours to red light already noticed, it is of primary importance that the proportion of red light should be carefully adjusted. Small variations in the amount of violet light are of minor importance, owing to the eye being less

* Abstract of a Paper read before Section A of the British Association at Bradford.

Digitized by Google

sensitive to such rays, and also because in mixing colours there is not the same tendency to develop a band of violet as we have seen occurs in the red, since yellow colours generally have complete absorption in the violet. The required absorption of the less refrangible rays can be effected by means of blue cupric salts. A solution of copper sulphate shows strong absorption at the extreme red of the spectrum, the absorption extending with diminishing intensity into the green. For practical purposes the light from the arc is modified by passage through pale blue glass coloured by means of copper. This coloured glass may conveniently take the form of a globe replacing the ordinary globe of the arc light.

ELECTRICITY WORKS ACCOUNTS.

Manchester Municipal Electric Supply Works.

Although the accounts of the Manchester undertaking for the year ended at March 31 last show that a material increase in the working expenditure per unit sold has taken place, yet the results in general are most satisfactory.

To have diminished the already low fuel charge of 1898 is a highly creditable achievement, while the item "Wages at Station" presents a figure, at 0·156d. per unit, little over half what it might reasonably have been expected to stand at. Owing to expenditure on mains which had proved defective, the charge in respect of repairs and renewals of mains has risen considerably, and has been the cause of a rise in the works costs in spite of the diminished generating costs. Another item which has seriously risen is that of rents, rates, and taxes. The chief seat of the rise in this item is in the rates, the charge on this account being £4,814 last year, as compared with £1,048 in the preceding year. The result of this increase has been to raise the collective management and property charges to 0·554d. per unit—a value decidedly above what it should be. The total costs, at 1·88d. per unit, are most satisfactory.

During the year the lamp connections rose from the equivalent of 217,457 8 c.p. lamps to 290,284—a rise of 17·3 per cent. The output made a greater stride, having reached 6,355,872 units sold, being an advance of 33·3 per cent. Last year's load factor at 12·9 per cent. was a slight improvement on that of 1898-9, which stood at 12·8 per cent.

In addition to the call made upon the revenue account in respect of renewal of mains a sum of £12,460 was withdrawn from the renewals suspense account to cover similar expenditure, while on account of the unfortunate breakdown at the Dickenson-street station in September of last year, when two 400 H.P. generating sets were wrecked, the reserve fund suffered to the extent of £7,070.

On Sept. 30 last year the price for supply to long-hour consumers was reduced from 1½d. to 1¼d. per unit. This was to the advantage of consumers to the extent of £2,873 in six months.

Glasgow Municipal Electric Supply Works.

Again this year the accounts of the Glasgow undertaking indicate excellent results. It is true that owing to the increased fuel expenditure both the generating and the total works costs have gone up, yet the increase in the latter two items has been but slight and more than neutralised in the total costs by the reduction which has taken place in the management and property charges. These charges have fallen from 0·59d. to 0·44d. per unit, and at the latter figure indicate a most commendable result in view of the low load-factor which obtains at Glasgow. The net result in the aggregate costs has been that they have dropped from 2·04d. to 1·98d. per unit.

As regards the progress in the business done, the lamp connections and the output bear convincing evidence. The former quantity advanced by nearly 26·5 per cent., and the latter by over 50 per cent. The load-factor, which was only 5·28 per cent. in 1898-9, was last year 6·28 per cent.

During the year the buildings at Port Dundas and at the Pollokshaws-road station have been nearly completed. In the former station steam plant to nearly 7,000 H.P. capacity and at the latter station to 2,200 H.P. is being installed, while further extensions of plant to about 5,000 H.P. are on order for the Port Dundas station, and to the extent of 2,200 H.P. for the Pollokshaws-road station.

The undertaking of the Kelvinside Electricity Co. (Ltd.) was acquired by the Corporation in August, 1899, and they are putting in about 1,000 H.P. of new plant.

The tariff for supply during the current year (1900-1901) is as follows:—Under the maximum demand system 6d. per unit for a quantity not exceeding the maximum demand for 365 hours in the year, and thereafter 2½d. per unit to 100-volt consumers, 2d. per unit to 200-volt consumers, and 1½d. to 250-volt consumers.

Under the fixed charge system, a fixed charge of 4s. 6d. per annum for each 8 c.p. lamp, or its equivalent fixed on the consumer's premises (or £7. 0s. 8d. per kw.) for 100-volt supply, 4s. 4d. per lamp for 200-volt supply, and 4s. per lamp for 250-volt supply, this charge being spread uniformly over the 12 months, and in addition a charge of 1½d. per unit by meter.

All consumers taking a supply for the equivalent of five hours or more per day for 365 days per annum to be charged throughout at 2½d. per unit for 100-volt supply, 2d. per unit for 200-volt supply, and 1½d. per unit for 250-volt supply.

There is a special rate of 3d. per unit charged to churches.

For domestic consumption only, a uniform charge of 3½d. per unit for 250-volt supply and 4d. for 100 and 200-volt supply is made without the use of demand indicators, and for motive power only, a uniform charge of 1½d. per unit for 250-volt supply, and 2d. per unit for 200-volt consumers is also applicable—no demand indicator being used.

The following is a list of electric supply works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared:—

MANCHESTER.—REMARKS—*a* Over-expended. *b* Includes £388 for current and £5 rental of meters. *c* Includes £124 stamp duty, £375 law and parliamentary charges, £23 insurances, £94 to Manchester Thrift Fund and £69 clothing. *d* Of which £12,000 was paid to City Fund and £2,000 carried to next year's accounts. *e* With sliding scale to 1·69d. per unit. *f* At option of consumer either at 5d. per unit by meter, with minimum charge of 8s. 4d. per quarter, or at the rate of £1. 15s. per quarter per kilowatt of demand when all consumer's devices are in use plus 1½d. per unit by meter. If motor supply is taken at 400 volts and is not less than 4 H.P. for 48 hours per week, the fixed charge under the latter scale is remitted. *g* Includes 2,139 as the equivalent in 8 c.p. in arc lamps and 51,000 as the equivalent in 8 c.p. lamps of motors representing 2,650 H.P. capacity. *h* Including balance of renewals suspense account. *i* Includes £409 to current and £121 to lamps for lighting works, also £555 sundries. *j* Includes £28 to insurance, £122 to Manchester Corporation Thrift Fund and £88 official clothing. *k* Paid to City Fund. *l* From Oct., 1899, with option at 1½d. per unit and £1. 15s. per quarter per unit of demand. *m* From Oct., 1899, with alternative of 2½d. per unit except where motors are run for 48 hours per week, when the fixed charge of £1. 15s. per quarter is remitted and current charged for at 1¼d. per unit.

GLASGOW.—REMARKS—*a* After deducting depreciation. *b* Over-expended. *c* On maximum demand system. After one hour of maximum demand 2½d. per unit for 100-volt supply, 2d. for 200-volt supply. *d* Includes £4,658 and £4,235 respectively on the Tontine and Claremont-street battery stations. *e* On maximum demand system, 6d. per unit for first hour of maximum demand at all pressures and thereafter 2½d. per unit for 100-volt supply, 2d. for 200-volt supply and 1½d. for 250-volt supply. *f* Per cent. to mean cap. expended *less depreciation*

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny
Editorial Publishing and Printing Offices,

2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to THE EDITOR.

All letters for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 0d.	16s. 0d.	8s. 6d.	

New Volumes of "THE ELECTRICIAN" *commence in April and October.*

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of THE ELECTRICIAN" *Printing and Publishing Company, Limited. The well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. ELTON YOUNG, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. FISHER and J. C. H. DARBY. Price 6s. net; abroad, 6s. 9d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. H. S. PHILLIPS. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints" on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. FISHER. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. RAPHAEL. Price 5s., post free.

MOTIVE POWER AND GEARING. By H. TREMLETT CARTER. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by DR. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d.; post free 13s. Vol. II. Price 12s. 6d.; post free, 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By DR. J. A. FLEMING. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. New Edition. 93 original illustrations, price 6s.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. New edition. Price 10s. 6d., post free; abroad 11s.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d. post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d.; post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free 2s. 2d. each; strong cloth 2s. 6d., post free 2s. 8d. each. Single Primers 2d., post free 2½d.

WIRELESS TELEGRAPHY: SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES. By Dr. O. J. LODGE. New Edition. Price 5s. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, ELECTRIC TRACTION, TELEGRAPHS, TELEPHONES, &c. A. C. CURTIS-HAYWARD, B.A. To January, 1900. Price 3s. 6d., post free.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By FRANCIS JEHL. Price 10s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

THE ELECTRIC ARC.—By MRS. AYRTON. This work is in the press and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. WADE. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. RAPHAEL. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

THE TELEPHONE.—By DANE SINCLAIR and F. C. RAPHAEL.

SPECIAL NOTICES.

NOW READY.—Vol. XLIV. of "THE ELECTRICIAN" (960 pages) bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of "THE ELECTRICIAN" (1878-1900) can now be supplied. These sets are very scarce, and early application should be made

NOW READY.—"THE ELECTRICIAN" READING CASE. Holds four copies of the Journal. Strongly made and corded for hanging. Price 1s.; post free, 1s. 4d.

AN ELECTRICAL HYPOTHESIS OF VITAL FUNCTIONS.

It is several years since Prof. J. CHUNDER BOSE, of Calcutta University, delighted and surprised English physicists, at a meeting of the British Association, by an exhibition of the neat and compact Hertzian wave apparatus which he had designed, and by his rehearsal of the principal experiments in optics with Hertzian waves. What investigators in Europe had been attempting with crude and clumsy apparatus, Prof. BOSE had accomplished in his laboratory at Calcutta with a pretty little set of instruments occupying no more space than an ordinary optical bench. Indeed, he carried the optical analogy experimentally much further than had been attempted in this country; and by his investigation of the properties of various substances in regard to Hertzian waves, he greatly extended the study of optical phenomena in the region of non-luminous long waves to which the Hertzian waves belong. Since that time both the scientific and the practical bearing of the Hertzian wave has been closely studied by numerous workers. Wireless telegraphy has leaped from the laboratory into the arena of public commerce and civilised arts; and the so-called "coherer"—in spite of its unhappy christening—has become an article of everyday use in the physical laboratory, and one of considerable and increasing importance in applied science. Probably on the scientific side no element of wireless telegraph apparatus has received more careful study than has the coherer; while, in the domain of practical wireless telegraphy, it has been, comparatively speaking, neglected. And it is certain that no physicist has devoted more time and attention to this item, nor has anyone educed more systematic and comprehensive information regarding its properties and physical laws, than has Prof. BOSE. The coherer has been the absorbing study of the past few years of his life; and, we may add, we trust he may enjoy many more years in which to push his researches further into the rich fields of still undiscovered truths, and to clear away some of the inspiring mysteries suggested by the extraordinary facts he has already succeeded in establishing. Viewed in the light of Prof. BOSE's researches, recent and of earlier date, physics and chemistry—even,

Digitized by Google

perhaps, biology—appear to be on the eve of a generalisation of unusual importance.

From time to time we have acquainted our readers with the progress of Prof. Bose's researches. We have now to invite their attention to an informative and profoundly suggestive Paper read by him at the recent meeting of the British Association at Bradford. In this Paper, which we reprint elsewhere, almost the latest stages in his systematic lines of research are recorded, and hypotheses are advanced and backed up by such apparently weighty evidence as must astonish physicists and biologists alike, and give them pause. Let us not, however, anticipate the astonishment of our readers, but proceed first to summarise the train of reasoning by which Prof. Bose seeks to explain half or more of physico-chemistry and scarcely less of the science of vital functions. Electric stimulus, or, rather, the behaviour of any substance under electric stimulus—is the key to the whole problem. Electric stimulus is the stress; the variously manifested behaviour is the strain which that stress produces. Within limits the ordinary law of elasticity holds, the ratio of stress to strain being constant; but, according to the physical properties of the substance strained, fatigue occurs when the stress is excessive. Recovery, either automatic or induced, may occur in specified conditions. We are to interpret these actions on a scale molecular, or atomic, or perhaps even sub-atomic, in magnitude. The electric stimulus directly actuates matter on this scale, and calls into effect a change of property or function which produces the corresponding outward phenomenon. Thus, in the iron-filings coherer the Hertzian wave generates an electric stimulus within the molecules of iron in the region where the waves act; and if the stimulus is of sufficient strength it will so stress the molecules that a decrease in the electrical resistance will ensue. But it is not essential to have actual filings; the iron may be continuous and homogeneous, and still the action will be the same, in so far as the metal is reached by the external waves. With some materials the stimulus produces a decrease of resistance; with others the change is just the reverse; and in many cases the direction of the change is determined by the vigour of the stimulus. Moreover, some materials under a definite stimulus quickly recover their normal state; others recover slowly, in similar circumstances, but may behave differently under stronger stimuli; others, again, may be "poisoned" by the injection into them of foreign materials, the effect of which is to convert them from quickly-recovering to non-recovering substances. Heat and mechanical vibration are effective in assisting recovery from fatigue, whether of the over-stimulated coherer or of the over-strained muscle or nerve. Indeed, the parallel between the behaviour of a coherer in an electric circuit and the behaviour of living tissue in its ordinary physiological functions is remarkably close; it is so close as to be suggestive of a common explanation. Prof. Bose indicates such an explanation in the electric stress-strain hypothesis, regarding vital functions as merely the manifestations of an electric stimulus in a substance (tissue) acting molecularly or atomically in the same manner as a so-called coherer does. We believe that Profs. Oliver Lodge and F. Gotch were the first to suggest a coherer theory of vision, propounding that the elements of the retina and optic nerve—acting in conjunction with the brain—constitute a number of coherer circuits, the luminous image on the retina corresponding in its action to the impinging Hertzian waves in an ordinary coherer. Prof. Bose carries this hypothesis much further, for he extends it into the domain of every form of differentiated living tissue. If his hypothesis is correct, not merely sight and the rest of our five senses, but also every functional change in every portion of living tissue is explicable in the same manner. It is a stupendous proposition for the physiologist. Will he accept it?

REVIEWS.

(Copies of any of the undermentioned works can be had from *The Electrician* office post free, on receipt of published price.)

Standard Polyphase Apparatus and Systems. By Maurice A. Oudin. (London: Sampson Low, Marston & Co. (Ltd.), 1900.)

This is a book well deserving of popularity amongst those who are interested in the electrical transmission of power. The work throughout has the characteristics of over condensation—a good quality merging into a bad; and has evidently been written from a breadth of view and judgment not commonly associated with the essentially practical nature of the information given. Of necessity, in attempting to deal with such a subject in a volume of this size the author has had to limit himself rigidly to descriptions of plant and systems, with the result that the book is rather more a convenient assemblage of facts, and contains information hitherto only available (by those conversant with the theory of the subject) from manufacturers' catalogues and descriptions of transmission plants in periodicals. Chapters XII. and XIV. are exceptions in this respect, however, in that they are devoted, the former to an excellent discussion of the considerations governing the choice of frequency, the latter to the calculation of transmission lines. The title of the book is, therefore, appropriated and naturally in consequence of the condensed nature of the treatment of the subject, its practical nature, but also because its writer is, too frequently we must say, somewhat careless in his terms of expression, it is necessary to warn the student from its perusal until he is perfectly familiar with the principles and theory of alternating and polyphase currents. To the engineering student who has thoroughly mastered the theory relating to this branch of electrical engineering a work like this is invaluable, as it serves to furnish him with a truer practical idea of the proportionate importance of various phenomena, and of the extent to which they enter into and influence practical work.

It is rather a pity that the author did not deal more adequately with the subject of resonance. Notwithstanding that in polyphase and transmission work generally the use of low frequencies is general, yet the E.M F. wave is generally rich in the higher harmonics, and these are apt to assert themselves on long transmission lines in an embarrassing way. To us in this relatively humid climate the author's sanguine remarks about the extended use of glass as the material for line insulators for pressures even up to 40,000 volts seem very strange. We notice, too, that oil insulators for the line are not referred to at all, so completely do they appear to have dropped out of use in America.

We have little but praise for the whole of the book after Chapter I., which deals with the definitions of alternate current terms. Careless expressions, such as "voltage drop due to power factor," rather mar the first two or three chapters, though the *matter* given is most useful and condensed. The author uses the term "shunt" as applied to the field windings of generators, motors and rotary converters in an incorrect and unusual sense. Throughout the book the field windings carrying current supplied by a separate exciter are termed "shunt" windings—a machine separately excited being referred to as "shunt wound." We must also take exception to the definition of the term "regulation" on p. 42, viz., ". . . the now commonly accepted definition is the percentage rise of the voltage when full non-inductive load is thrown off the generator, speed and the field excitation remaining constant."

The subject dealt with is one singularly difficult of intelligible treatment without the constant use of mathematical symbols and expressions. Although, however, there is comparatively little of these, once the student has learnt the author's language he will find some of the more difficult points treated with unusual lucidity of expression.

THE BRITISH ASSOCIATION MEETING AT BRADFORD.

Thursday, Sept. 6.

The presidential address to Section A was delivered by Dr. Joseph Larmor, F.R.S., Pres. C.P.S. We complete our reprint of it this week. Prof. G. F. FitzGerald then communicated a note on M. Cremieu's experiment in search of a magnetic effect of a moving electric charge. Contrary to Rowland's effect, M. Cremieu's experiments led to negative results. The object of the note was to point out that both results might be correct, since the methods were different, Rowland having looked for a direct effect upon a magnet, whilst Cremieu looked for an induction current in a wire. The absence of any effect in the latter case Prof. FitzGerald suggested might be due to omission of some term in our electro-dynamic equations. Prof. A. Gray stated that he had already commenced a research upon the point in question. A lengthy discussion ensued.

Dr. F. T. Trouton, F.R.S., then read a Paper on "The Creeping of Liquids and the Surface Tension of Mixtures." He said that pure liquids did not creep, but only mixtures. Ether and benzene increased the rate of creeping. The more volatile and higher the surface tension the less ought the effect to be; but he observed that the opposite took place, and that their effect was to increase the creeping. The rate of creeping over zinc is three times as great as that over any other substance.

Prof. FitzGerald then read the report of the Committee on Radiation in a Magnetic Field, and stated that the work in which the late Prof. Thomas Preston was engaged had been taken up by Mr. W. E. Thrift. He proposed that copies of Preston's photographs should be produced on an enlarged scale, especially the iron spectrum, which showed doublets, triplets, quartets, and sextets, and hoped that by more careful analysis they might be more clearly understood.

Mr. H. Ramage read an interesting and important Paper on "A Method of Investigating Correspondences Between Spectra"; which was followed by a Paper by Mr. G. J. Burch, F.R.S., "On an Experiment on Simultaneous Contrast." Mr. J. W. Gifford read a Paper on a "Quartz-Calcite Symmetrical Doublet."

In the afternoon a reception was held at the Technical College, when a Paper was read by Mr. Arthur Dufton and Mr. Walter M. Gardner on the "Production of an Artificial Light of the same character as Sunlight," forming part of the proceedings of Section A. They gave a very pretty exhibition in contrasts of colours.

Friday, Sept. 7.

In Section A the President, Dr. J. Larmor, read a Paper on the "Dynamical Statistics of Gas Theory, illustrated by Meteor Swarms and Optical Rays," which was followed by one on the "Partition of Molecular Energy," by Prof. G. H. Bryan, F.R.S. A lengthy discussion followed, in which Prof. G. F. FitzGerald pointed out that the energy of translation of molecules ought ultimately to be frittered away by their collisions into higher and higher vibrations, and that if they behaved like billiard balls they ought to lose all their energy in 15 minutes. But this does not happen, and the kinetic theory does not explain why. The radiation from radio-active substances may be the result of its happening to some extent in some bodies, but why it should take place only in some bodies and then only very slightly is as great a mystery as if it did not take place at all. No satisfactory explanation has yet been given of how radiant energy is converted into energy of translation of molecules.

Prof. W. B. Morton gave a note on the "Propagation of Electric Waves along Parallel Wires," and Dr. S. H. Burbury, F.R.S., "On the Vector Potential of Electric Currents in a Field where Disturbances are Propagated with Finite Velocity."

Saturday, Sept. 8.

In Section A reports were presented of the Committee on the most suitable Method of Determining the Magnetic Force on Board Ship; and of the Committee on the Size of Pages of Scientific Periodicals. Sir William Preece gave an account of his experiments on wireless telephony, between the islands or rocks known as the Skerries and the mainland of Anglesey; and also more recently between Rathlin Island, on the north coast of Ireland, and the mainland. He explained that wireless telephony across the sea is now a practical and commercial system. The preliminary experiments show that telephonic communication has been maintained under similar conditions as Morse signalling between parallel wires at a distance of 8 miles, and he suggested that signalling between ships may be effected by means of a circuit formed of copper wire terminating at each end of the ship in the sea, and passing over the masts, using simple telephones.

Mr. C. E. S. Phillips read a Paper on "The Apparent Emission of Cathode Rays from an Electrode at Zero Potential." He showed that the green patches which often appear on the surface of the walls of a Röntgen-ray bulb while a discharge is passing are due to irregularities on the surface of the cathode, as they could be made to alter their position when a movable cathode was used, and, moreover, that there was strong evidence for regarding an emission of gas in jets from the electrodes to take place. Prof. F. G. Baily read a Paper on a "Lecture-room Volt-and-Ammeter," which was followed by a Paper by Mr. J. B. B. Burke on "The Phosphorescent Glow in Gases," proving that the glow produced by the passage of a discharge through a gas consisted of unelectrified particles which, as they moved through the gas, produced conductivity, but were quickly destroyed in the ionised gas. The Paper contained an account of a series of experiments to investigate various properties of the glow. A discussion of some length ensued. Prof. J. C. Bose read a Paper "On the Similarity of the Effect of Electrical Stimulus on Inorganic and Living Substances."

Sections B and G did not meet.

Monday, Sept. 10.

Section A divided into two parts—for mathematics and meteorology. There were no Papers read which had any special bearing on electricity.

In Section G several interesting Papers were read. The first was by Mr. J. G. W. Aldridge, "On the Automobile for Electric Street Traction." This was followed by a communication from Mr. A. Mallock, "On Measurement of the Tractive Force, Resistance and Acceleration of Trains," in which he described some experiments recently made on electric and other railways, the object of the experiments being to determine the acceleration, tractive force, and running resistance to which the trains are subject. A short pendulum was used, the free vibrations of which are considerably damped. This is suspended on the moving body. The angle which it makes with the vertical is a measure of the acceleration at any instant, and variations in the angle are recorded on a uniformly moving paper, on which also are recorded the revolutions of one of the wheels of the carriage, by which means a measure is obtained of the speed and acceleration of the carriage. From the speed and power supplied, together with the pendulum observations, the resistance to and efficiency of electric and other motor vehicles can be easily obtained.

Sir W. H. Preece, F.R.S., read a Paper on "The Manchester and Liverpool Express Railway." It dealt with the mono-rail line which has been projected by Mr. Behr between Manchester and Liverpool for express passenger accommodation. Mr. F. J. Behr then read a Paper on "Brakes and Signals," which was a continuation of the last. Mr. Alfred H. Gibbings read a Paper on "The Design and Location of Electric Generating Stations," and Mr. T. Barker made a communication on a "Combination Integrating Wattmeter and Maximum Demand Indicator." Abstracts of all these Papers will appear in our columns.

Tuesday, Sept. 11.

In Section A a lengthy discussion on "Ions" was opened by Prof. G. F. FitzGerald. He considered that "conductivity" was a better word than "ionisation." The "conductivity" in liquids was different from that in gases, for in gases there is

Digitized by Google

evidence of masses smaller than atoms, whereas there is no evidence of such in liquids. Then conductivity of liquids is connected with many other properties—their solution, chemical affinity, the power of coagulation, osmotic pressure (which is related to the freezing point and boiling point). We have no satisfactory theory of what is going on in ionisation. There are many difficulties in the ordinary theories of ionisation, and there is no consistent explanation of (1) the instability of ions; (2) the source of energy of ions for dissociation; (3) the migration of ions with different velocities—some move faster than others. Prof. FitzGerald said these were difficulties which required to be removed. German physicists were contented with the term "ionisation." But hydrogen and chlorine when separated wander about without any tendency to re-combine. This is a state dynamically impossible, and until we get a dynamical explanation it is better to acknowledge our ignorance. As regards the conductivity of gases very little was known until the conductivity of gases produced by X-rays, &c., was studied. For a long time it was supposed that dust played an important part in the conductivity of gases, but this has now been refuted.

The term "ionisation" should, he thought, be used only to denote the presence of charged atoms, and he suggested the word "electronisation" for the conducting state of a gas in which there were five electrons. Lenard rays, Becquerel rays, Röntgen rays, and strong currents, give electronisation. But it is probable that both electronisation and ionisation take place in a gas, and that there are electrons, atoms and groups of molecules with a charge which co-operates in the conductivity of a gas. An electron appears to possess the power of carrying a group of molecules after it, like a mother with a dozen children as she tries to make her way through a crowded thoroughfare. Prof. FitzGerald then maintained that the small carriers of electricity or corpuscles, smaller than atoms, which Prof. J. J. Thomson had found to exist in a conducting gas, were electrons, as they have the same mass as the oscillating changes in an atom to which the vibrations of light are due, as is shown by the Zeeman effect, and the fact that the mass of these free carriers of electricity is the same in all conducting gases. He maintained, however, that there was very little evidence to justify the assumption that atoms are made up of electrons, but the best evidence in its favour is that it accounts for the change in the size of objects moving through the ether, which he believed was the correct explanation of Michelson's experiments, according to which the earth's diameter is altered by 4cm. in consequence of its motion through the ether.

The following points require an answer:—

1. What is the cause of ionisation, and what is its nature? Why do not ions exist in pairs?
2. What is the source of the energy that keeps ions apart?
3. Ionisation does not obey the law of dissociation. With sufficient dilution the law does not hold.
4. Different ions move with different velocities.
5. What is the nature of the double layer? Why do some substances attract positive electricity and others negative?
6. Ionisation in gases and liquids not the same.
7. Do electrons gravitate, and have they a material nucleus?
8. The theory of magnetism and nature of paramagnetism.

The President, Dr. J. Larmor, suggested that the high specific inductive capacity of water might be due to a large electric moment in the molecules as the positive and negative ions may be far apart. He also remarked that he thought atoms could not be broken up, but that what happened during conductivity is an interchange of electrons, and that the same effect took place at the electrodes, whether in gases or in liquids.

Prof. H. E. Armstrong said that the chemist regarded an atom as a sacred structure, and would not admit that it could be broken up, but he was ready to admit that the displacement of electrons was quite possible. Stability is what marks an atom; it has an assymetric structure and a definite combining power. He regarded conductivity in gases as being due to the same process as in liquids. He believed that the conductivity of gases was dependent on the presence of vapours; for Dewar had shown that cooling a vacuum tube destroyed the conductivity of the gas within, showing conclusively, he thought, that the vapour thus removed was essential to the passage of electricity through the gas. Neither is a liquid *per se* an electrolyte. Oxidation does not take place except in the presence of conducting water.

A manuscript was read from Mr. Whetham in which he maintained that ions are handed on from molecule to molecule.

Principal Oliver Lodge pointed out that Faraday's law for liquids implied that electrons were not separated from ions. In gases, he thought, there were two processes, but whether a gas conducted electrolytically or not he considered had not yet been proved. He remarked further that though ions move with different velocities, electricity goes at the same rate. He added that he hoped the electric theory of matter would turn out correct.

Principal Glazebrook asked what produced the first electron which led to the interchange in atoms. Mr. W. J. Pope also made some suggestive remarks.

Dr. H. C. Pocklington then read a Paper on "The Radiation of a Black Body on the Electromagnetic Theory of Light."

Wednesday, Sept. 12.

In Section A, the report of the Electrical Standards committee was read by Mr. R. T. Glazebrook. The question of the selection of a wire for the construction of the standards is still under the consideration of the committee. During the year the resistance coils and other apparatus belonging to the committee have been removed to Richmond. It is interesting to note that the case containing the original coils of the Association bears the words, "To be deposited at Kew." After many wanderings these coils, of memorable fame, have at last reached their home and resting place—the National Physical Laboratory. Mr. E. H. Griffiths, F.R.S., described a form of Wheatstone Bridge, and Mr. R. S. Whipple gave a note on "An Improved Standard Resistance Coil," after which Mr. G. E. Petavel described some experiments on the explosive pressures of gaseous mixtures, which were an extension of the work originally done by Bunsen at atmospheric pressures to initial pressures of 100 or 200 atmospheres. It was proved that compressed gases had a very high *thermal* conductivity. Mr. Petavel proposes to investigate the phenomenon of dissociation at very high pressures.

The President (Dr. J. Larmor) then read a Paper "On the Relation of Radiation to Temperature," and emphasised the fact that Balfour-Stewart was the co-discoverer with Kirchhoff of the law of the equality of the radiation and absorption of bodies surrounded by others at the same temperature, and therefore in a steady state.

A Paper, by Dr. S. P. Langley, "On the Infra-red Solar Spectrum," was then read by the recorder (Prof. W. Watson). It was a continuation of a communication made six years ago by Dr. Langley himself to the British Association at Oxford. That elegant piece of research has since been diligently pursued at the Smithsonian Institute. Only the results obtained were given. The apparatus used in this as in the preceding investigation had not, it was stated, as yet been fully described.

The monumental work which Dr. Langley has, without either haste or pause, like all true scientists, successfully carried out during the last 10 years with the bolometer, beginning—if our memory serves us rightly—in that beautiful investigation of the radiation from glow-worms and fire-flies, which proved that all the energy that such creatures emit, small though it be, is always luminous, and then, leading up as that research has done, like a stepping-stone to the careful study of the invisible spectrum of the sun in the infra-red, has we believe, though it came last, not been the least important, but possibly the most lasting, of the many valuable contributions which have helped, some to a greater others to a less degree, to maintain that high standard which Section A has always held amongst its sister sections. But it is to the President, Dr. Larmor, however, that the particularly brilliant success of this section is chiefly

Digitized by Google

due. We can call to mind many accomplished presidents and many successful meetings, but we cannot recall one that has left more pleasing memories than the one over which Dr. Larmor has presided with so much ability, with so much grace and dignity. Throughout the whole proceedings one quality shone out before every other, great as no doubt these were—his mind was sincere and open.

LIST OF THE ELECTRICAL PAPERS READ AT THE BRITISH ASSOCIATION MEETING AT BRADFORD.

The following is a complete list of the electrical Papers read and reports presented at the Bradford meeting of the British Association, September 6 to September 13, 1900:—

SECTION A.—*Mathematical and Physical Science.*

"Note on M. Cremieu's Experiment," by Prof. G. F. Fitzgerald, F.R.S.
"On the Creeping of Liquids and the Surface Tension of Mixtures," by Dr. F. T. Trouton, F.R.S.
"An Experiment on Simultaneous Contrast," by G. J. Burch, F.R.S.
"The Production of an Artificial Light of the same Character as Daylight," by A. Dufton and W. M. Gardner.
"On the Partition of Molecular Energy," by Prof. G. H. Bryan, F.R.S.
Note "On the Propagation of Electric Waves along Parallel Wires," by Prof. W. B. Morton.
"On the Vector Potential of Electric Currents in a Field where Disturbances are propagated with Finite Velocity," by Dr. S. H. Burbury, F.R.S.
"On the Application of the Electric Telegraph to the Furtherance of Eclipse Research," by Prof. David P. Todd.
"On the Similarity of the Effect of Electrical Stimulus on Inorganic and on Living Substances," by Prof. J. C. Bose.
"Wireless Telegraphy," by Sir William Preece, F.R.S.
"On the Apparent Emission of Cathode Rays from an Electrode at Zero Potential," by C. E. S. Phillips.
"On Volta-Electromotive Force of Alloys," by Dr. G. Gore, F.R.S.
"On a Lecture Room Volt-and-Ammeter," by Prof. F. G. Baily.
"On the Phosphorescent Glow in Gases," by J. B. B. Burke.
"A Form of Wheatstone Bridge," by E. H. Griffiths, F.R.S.
"Note on an Improved Standard Resistance Coil," by R. S. Whipple.
"Note on the Explosive Pressures of Gases," by G. E. Petavel.
"On the Relation of Radiation to Temperature," by Dr. J. Larmor, F.R.S.
Report of Committee on Radiation in a Magnetic Field.
Report of the Committee on the most suitable Method of Determining the Magnetic Force on board ship.
Report of the Committee on the Sizes of Pages of Scientific Periodicals.
Report of the Electrical Standards Committee.

SECTION B.—*Chemistry.*

"On the Specific Heat of Gases at Temperatures up to 400deg.," by H. B. Dixon, F.R.S., and F. W. Rixon, B.Sc.
"On the Crystalline Structure of Metals," by Prof. J. A. Ewing, F.R.S., and W. Rosenhain, B.A.
"On the Electric Conductivity of the Alloys of Iron," by Prof. Barrett, F.R.S.
"On some New Chemical Compounds discovered by the Use of the Electric Furnace," by C. S. Bradley.
Report of the Committee on the Teaching of Science in Elementary Schools.
Report of the Committee on the Nature of Alloys.
Report of the Committee on the Electrolytic Methods of Quantitative Analysis.

SECTION G.—*Mechanical Science.*

"Resistance of Road Vehicles to Traction," by Prof. Hele Shaw, F.R.S.
"Power Generation—Comparative cost by the Steam Engine, Water Turbine, and Gas Engine," by J. B. C. Kershaw.
"The Automobile for Electric Street Traction," by J. G. W. Aldridge.
"The Manchester and Liverpool Express Railway," by Sir W. H. Preece, F.R.S.
"The Manchester and Liverpool Express Railway—Signals and Brakes," by F. J. Behr.
"The Construction of Large Dynamos, as exemplified at the Paris Exhibition," by Prof. S. P. Thompson, F.R.S.
"Recent Tramway Construction," by W. Dawson.
"Measurement of the Tractive Force, Resistance, and Acceleration of Trains," by A. Mallock.
"On a Combination Integrating Wattmeter and Maximum Demand Indicator," by T. Barker and Prof. Ewing, F.R.S.
"The Design and Location of Electric Generating Stations," by A. H. Gibbings.

MISCELLANEOUS SECTIONS.

"Electrical Changes in Mammalian Nerve" (Report) (Section D), by Dr. McDonald.
"Municipal Trading," by Arthur Priestman. (Section F.)
"Recent Changes affecting the Legal and Financial Position of Local Authorities in England," by F. W. Hirst. (Section F.)

DR. JOSEPH LARMOR'S PRESIDENTIAL ADDRESS TO SECTION A OF THE BRITISH ASSOCIATION AT BRADFORD.*

(*Concluded from page 736*).

Let us now return to the general question whether our definition of a dynamical system may not be too wide. As a case in point, the single principle of action has been shown to provide a definite and sufficient basis for electro-dynamics; yet when, for example, one armature of an electric motor pulls the other after it without material contact, and so transmits mechanical power, no connection between them is indicated by the principle such as could by virtue of internal stress transmit the pull. The essential feature of the transmission of a pull by stress across a medium is that each element of volume of the medium acts by itself, independently of the other elements. The stress excited in any element depends on the strain or other displacement occurring in that element alone; and the mechanical effect that is transmitted is considered as an extraneous force applied at one place in the medium, and passed on from element to element through these internal pressures and tractions until it reaches another place. We have, however, to consider two atomic electric charges as being themselves some kind of strain configurations in the æther; each of them already involves an atmosphere of strain in the surrounding æther which is part of its essence, and cannot be considered apart from it; each of them essentially pervades the entire space, though on account of its invariable character we consider it as a unit. Thus we appear to be debarred from imagining the æther to act as an elastic connection which is merely the agent of transmission of a pull from the one nucleus to the other, because there are already stresses belonging to and constituting an intrinsic part of the terminal electrons, which are distributed all along the medium. Our action criterion of a dynamical system, in fact, allows us to reason about an electron as a single thing, notwithstanding that its field of energy is spread over the whole medium; it is only in material solid bodies, and in problems in which the actual sphere of physical action of the molecule is small compared with the smallest element of volume that our analysis considers, that the familiar idea of transmission of force by simple stress can apply. Whatever view may ultimately commend itself, this question is one that urgently demands decision. A very large amount of effort has been expended by Maxwell, Helmholtz, Heaviside, Hertz, and other authorities in the attempt to express the mechanical phenomena of electrical action in terms of a transmitting stress. The analytical results up to a certain point have been promising, most strikingly so at the beginning, when Maxwell established the mathematical validity of the way in which Faraday was accustomed to represent to himself the mechanical interactions across space, in terms of a tension along the lines of force equilibrated by an equal pressure preventing their expansion sideways. According to the views here developed, that ideal is an impossible one; if this could be established to general satisfaction the field of theoretical discussion would be much simplified.

This view that the atom of matter is, so far as regards physical actions of the nature of a structure in the æther involving an atmosphere of æthereal strain all around it, not a small body which exerts direct actions at a distance on other atoms according to extraneous laws of force, was practically foreign to the eighteenth century, when mathematical physics was modelled on the Newtonian astronomy and dominated by its splendid success. The scheme of material dynamics, as finally compactly systematised by Lagrange, had therefore no direct relation to such a view, although it has proved wide enough to include it. The remark has often been made that it is probably owing to Faraday's mathematical instinct, combined with his want of acquaintance with the existing analysis, that the modern theory of the æther obtained a start from the electric side. Through his teaching and the weight of his authority, the notion of two electric currents exerting their mutual forces by means of an intervening medium, instead of by direct attraction across space, was at an early period firmly grasped in this country. In 1845 Lord Kelvin was already mathematically formulating, with most suggestive success, continuous elastic connections, by whose strain the fields of activity of electric currents or of electric distributions could be illustrated; while the exposition of Maxwell's interconnected scheme, in the earlier form in which it relied on concrete models of the electric action, goes back almost to 1860. Corresponding to the two physical ideals of isolated atoms exerting attraction at a distance, and atoms operating by atmospheres of æthereal strain, there are, as already indicated, two different developments of dynamical theory. The original Newtonian equations of motion determined the course of a system by expressing the rates at which the velocity of each of its small parts or elements is changing. This method is still fully applicable to those problems of gravitational astronomy in which dynamical explanation was first successful on a grand scale, the planets being treated as point-masses, each subject to the gravitational attraction of the other bodies. But the more recent development of the dynamics of complex systems depends on

* Delivered September 6, 1900.

Digitized by Google

the fact that analysis has been able to reduce within manageable limits the number of varying quantities whose course is to be explicitly traced, through taking advantage of those internal relations of the parts of the system that are invariable, either geometrically or dynamically. Thus, to take the simplest case, the dynamics of a solid body can be confined to a discussion of its three components of translation and its three components of rotation, instead of the motion of each element of its mass. With the number of independent co-ordinates thus diminished, when the initial state of the motion is specified the subsequent course of the complete system can be traced; but the course of the changes in any part of it can only be treated in relation to the motion of the system as a whole. It is just this mode of treatment of a system as a whole that is the main characteristic of modern physical analysis. The way in which Maxwell analysed the interactions of a system of linear electric currents, previously treated as if each were made up of small independent pieces or elements, and accumulated the evidence that they formed a single dynamical system, is a trenchant example. The interactions of vortices in fluid form a very similar problem, which is of special note, in that the constitution of the system is there completely known in advance, so that the two modes of dynamical exposition can be compared. In this case the older method forms independent equations for the motion of each material element of the fluid, and so requires the introduction of the stress—here the fluid pressure—by which dynamical effect is passed on to it from the surrounding elements: it corresponds to a method of contact action. But Helmholtz opened up new ground in the abstract dynamics of continuous media when he recognised (after Stokes) that, if the distribution of the velocity of spin at those places in the fluid where the motion is vortical be assigned, the motion in every part of the fluid is therein kinematically involved. This, combined with the theorem of Laggrange and Cauchy, that the spin is always confined to the same portions of the fluid, formed a starting point for his theory of vortices, which shows how the subsequent course of the motion can be ascertained without consideration of pressure or other stress.

The recognition of the permanent state of motion constituting a vortex ring as a determining agent as regards the future course of the system was in fact justly considered by Helmholtz as one of his greatest achievements. The principle had entirely eluded the attention of Lagrange and Cauchy and Stokes, who were the pioneers in this fundamental branch of dynamics, and had virtually prepared all the necessary analytical material for Helmholtz's use. The main import of this advance lay, not in the assistance which it afforded to the development of the complete solution of special problems in fluid motion, but in the fact that it constituted the discovery of the types of permanent motion of the system, which could combine and interact with each other without losing their individuality,* though each of them pervaded the whole field. This rendered possible an entirely new mode of treatment; and mathematicians who were accustomed, as in astronomy, to aim directly at the determination of all the details of the special case of motion, were occasionally slow to apprehend the advantages of a procedure which stopped at formulating a description of the nature of the interaction between various typical groups of motions into which the whole disturbance could be resolved.

The new train of ideas introduced into physics by Faraday was thus consolidated and emphasised by Helmholtz's investigations of 1858 in the special domain of hydro-dynamics. In illustration let us consider the fluid medium to be pervaded by permanent vortices circulating round solid rings as cores: the older method of analysis would form equations of motion for each element of the fluid, involving the fluid pressure, and by their integration would determine the distribution of pressure on each solid ring, and thence the way it moves. This method is hardly feasible even in the simplest cases. The natural plan is to make use of existing simplifications by regarding each vortex as a permanent reality, and directly attacking the problem of its interactions with the other vortices. The energy of the fluid arising from the vortex motion can be expressed in terms of the positions and strengths of the vortices alone; and then the principle of action, in the generalised form which includes steady motional configurations as well as constant material configurations, affords a method of deducing the motions of the cores and the interactions between them. If the cores are thin they in fact interact mechanically, as Lord Kelvin and Kirchhoff proved, in the same manner as linear electric currents would do, though the impulse thence derived towards a direct hydro-kinetic explanation of electromagnetics was damped by the fact that repulsion and attraction have to be interchanged in the analogy. The conception of vortices, once it has been arrived at, forms the natural physical basis of investigation, although the older method of determining a distribution of pressure-stress throughout the fluid and examining how it affects the cores is still possible; that stress, however, is not simply transmitted, as it has to maintain the changes of velocity of the various portion of the fluid. But if the vortices have no solid cores we are at a loss to know where even this pressure can be considered as applied to them; if we follow up the stress we lose the vortex; yet a fluid vortex can, nevertheless, illustrate an atom of matter, and we can consider such atoms as exerting mutual forces, only these forces cannot be considered as transmitted through the agency of fluid pressure. The reason is that the vortex cannot now be identified with a mere core bounded by a definite surface, but is essentially a configuration of motion extending throughout the medium.

Thus we are again in face of the fundamental question whether all attempts to represent the mechanical interactions of electro-dynamic systems, as transmitted from point to point by means of simple stress, are not doomed to failure; whether they do not, in fact, introduce unnecessary and insurmountable difficulty into the theory. The idea of identifying an atom with a state of strain or motion, pervading the region of the æther around its nucleus, appears to demand wider views as to what constitutes dynamical transmission. The idea that any small portion of the primordial medium can be isolated, by merely introducing tractions acting over its surface and transmitted from the surrounding parts, is no longer appropriate or consistent: a part of the dynamical disturbance in that element of the medium is on this hypothesis already classified as belonging to, and carried along with, atoms that are outside it but in its neighbourhood—and this part must not be counted twice over. The law of Poynting relating to the paths of the transmission of energy is known to hold in its simple form only when the electric charges or currents are in a steady state; when they are changing their positions or configurations their own fields of intrinsic energy are carried along with them.

It is not surprising, considering the previous British familiarity with this order of ideas, that the significance for general physics of Helmholtz's doctrine of vortices was eagerly developed in this country, in the form in which it became embodied through Lord Kelvin's famous illustration of the constitution of the matter, as consisting of atoms with separate existence and mutual interactions. This vortex-atom theory has been a main source of physical suggestion because it presents, on a simple basis, a dynamical picture of an ideal material system, atomically constituted, which could go on automatically without extraneous support. The value of such a picture may be held to lie, not in any supposition that this is the mechanism of the actual world laid bare, but in the vivid illustration it affords of the fundamental postulate of physical science, that mechanical phenomena are not parts of a scheme too involved for us to explore, but rather present themselves in definite and consistent correlations, which we are able to disentangle and apprehend with continually increasing precision.

It would be an interesting question to trace the origin of our preference for a theory of transmission of physical action over one of direct action at a distance. It may be held that it rests on the same order of ideas as supplies our conception of force; that the notion of effort which we associate with change of the motion of a body involves the idea of a mechanical connection through which that effort is applied. The mere idea of a transmitting medium would then be no more an ultimate foundation for physical explanation than that of force itself. Our choice between direct distance action and mediate transmission would thus be dictated by the relative simplicity and coherence of the accounts they give of the phenomena: this is, in fact, the basis on which Maxwell's theory had to be judged until Hertz detected the actual working of the medium. Instantaneous transmission is to all intents action at a distance, except in so far as the law of action may be more easily formulated in terms of the medium than in a direct geometrical statement.

In connection with these questions it may be permitted to refer to the eloquent and weighty address recently delivered by M. Poincaré to the International Congress of Physics. M. Poincaré accepts the principle of least action as a reliable basis for the formulation of physical theory, but he imposes the condition that the results must satisfy the Newtonian law of equality of action and reaction between each pair of bodies concerned, considered by themselves; this, however, he would allow to be satisfied indirectly, if the effects could be traced across the intervening æther by stress, so that the tractions on the two sides of each ideal interface are equal and opposite.* As above argued, this view appears to exclude *ab initio* all atomic theories of the general type of vortex atoms, in which the energy of the atom is distributed throughout the medium instead of being concentrated in a nucleus; and this remark seems to go to the root of the question. On the other hand, the position here asserted is that recent dynamical developments have permitted the extension of the principle of action to systems involving permanent motions, whether obvious or latent, as part of their constitution; that on this wider basis the atom may itself involve a state of steady disturbance extending through the medium, instead of being only a local structure acting by push and pull. The possibilities of

* We may compare G. W. Hill's more recent introduction of the idea of permanent orbits into physical astronomy.

* *Cf.* also Hertz on the electromagnetic equations, § 12, *Wied. Ann.*, 1890. The problem of merely replacing a system of forces by a statical stress is widely indeterminate, and therefore by itself unreal; the actual question is whether any such representation can be co-ordinated with existing dynamics,

Digitized by Google

mical explanation are thus enlarged. The most definite type odel yet imagined of the physical interaction of atoms through ether is, perhaps, that which takes the æther to be a rotationally ic medium after the manner of MacCullagh and Rankine, and s the ultimate atom include the nucleus of a permanent rota-l strain-configuration, which as a whole may be called an ron. The question how far this is a legitimate and effective l stands by itself, apart from the dynamics which it illustrates ; all representations it can only cover a limited ground. For nce, it cannot claim to include the internal structure of the eus of an atom or even of an electron ; for purposes of physical y that problem can be put aside, it may even be treated as utable. All that is needed is a postulate of free mobility of this eus through the æther. This is definitely hypothetical, but it t an unreasonable postulate because a rotational æther has the erties of a perfect fluid medium except where differentially ional motions are concerned, and so would not react on the on of any structure moving through it except after the manner apparent change of inertia. It thus seems possible to hold uch a model forms an allowable representation of the dynamical ty of the æther, as distinguished from the complete constitution e material nuclei between which that medium establishes ection.

any rate, models of this nature have certainly been most helpful axwell's hands towards the effective intuitive grasp of a scheme ations as a whole, which might have proved too complex for act unravelment in detail. When a physical model of concealed mical processes has served this kind of purpose, when its con- has been explored and estimated, and has become familiar gh the introduction of new terms and ideas, then the ladder by 1 we have ascended may be kicked away, and the scheme of relations 1 the model embodied can stand forth in severely abstract form. d many of the most fruitful branches of abstract mathematical sis itself have owed their start in this way to concrete physical ptions. This gradual transition into abstract statement of cal relations in fact amounts to retaining the essentials of our ing models while eliminating the accidental elements involved em ; elements of the latter kind must always be present because wise the model would be identical with the thing which it sents, whereas we cannot expect to mentally grasp all aspects of ontent of even the simplest phenomena. Yet the abstract stand- is always attained through the concrete ; and for purposes of iction such models, properly guarded, do not perhaps ever lose value ; they are just as legitimate aids as geometrical diagrams, hey have the same kind of limitations. In Maxwell's words, the sake of persons of these different types scientific truth d be presented in different forms, and should be regarded as ly scientific whether it appear in the robust form and the vivid ring of a physical illustration, or in the tenuity and paleness of bolical expression." The other side of the picture, the neces- incompleteness of even our legitimate images and modes of sentation, comes out in the despairing opinion of Young romatics," 1817), at a time when his faith in the undulatory of light had been eclipsed by Malus's discovery of the mena of polarisatian by reflection, that this difficulty "will bly long remain, to mortify the vanity of an ambitious philo- , completely unresolved by any theory": not many years ards the mystery was solved by Fresnel.

is process of removing the intellectual scaffolding by which our ledge is reached, and preserving only the final formulæ which s the correlations of the directly observable things, may more- eadily be pushed too far. It asserts the conception that the rse is like an enclosed clock that is wound up to go, and that lingly we can observe that it is going, and can see some of its superficial movements, but not much of them ; that thus, by t observation and use of analogy, we can compile, in merely tabular information as to the manner in which it works and is likely on working, at any rate for some time to come ; but that any pt to probe the underlying connection is illusory or illegimate. heoretical precept this is admirable. It minimises the danger ignoring or forgetting the limitations of human faculty, which ly utilise the imperfect representations that the external world sses on our senses. On the other hand such a reminder has been required by the master minds of modern science, from rtes and Newton onwards, whatever their theories may have Its danger as a dogma lies in its application. Who is to , without risk of error, what is essential fact and what is ctual scaffolding ? To which class does the atomic theory of r belong ? That is, indeed, one of the intangible things which uggested may be thrown overboard in sorting out and classify- ur scientific possessions. Is the mental idea or image, which sts, and alone can suggest, the experiment that adds to our ete knowledge, less real than the bare phenomenal uniformity it has revealed ? Is it not, perhaps, more real in that the mities might not have been there in the absence of the mind to ve them ?

time is now left for review of the methods of molecular dynamics. Here our knowledge is entirely confined to steady states of the molecular system : it is purely statical. In ordinary statics and the dynamics of undisturbed steady motions, the form of the energy function is the sufficient basis of the whole subject. This method is extended to thermo-dynamics by making use of the mechanically available energy of Rankine and Kelvin, which is a function of the bodily configuration and chemical constitution and temperature of the system, whose value cannot under any circumstances spontaneously increase, while it will diminish in any operation which is not reversible. In the statics of systems in equilibrium or in steady motion, this method of energy is a particular case of the method of action ; but in its extension to thermal statics it is made to include chemical as well as configurational changes, and a new point appears to arise. Whether we do or do not take it to be possible to trace the application of the principle of action throughout the process of chemical combination of two molecules, we certainly here postulate that the static case of that principle, which applies to steady systems, can be extended across chemical combinations. The question is suggested whether extension would also be valid to transformations which involve vital processes. This seems to be still considered an open question by the best authorities. If it be decided in the negative a distinction is involved between vital and merely chemical processes.

It is now taken as established that vital activity cannot create energy, at any rate in the long run, which is all that can from the nature of the case to be tested. It seems not unreasonable to follow the analogy of chemical actions, and assert that it cannot in the long run increase the mechanical availability of energy—that is, considering the organism as an apparatus for transforming energy without being itself in the long run changed. But we cannot establish a Carnot cycle for a portion of an organism, nor can we do so for a limited period of time ; there might be creation of availability accompanied by changes in the organism itself, but compensated by destruction and the inverse changes a long time afterwards. This amounts to asserting that where, as in a vital system or even in a simple molecular combination, we are unable to trace or even assert complete dynamical sequence, exact thermo-dynamic statements should be mainly confined to the activity of the existing organism as a whole ; it may transform inorganic material without change of energy and without gain of availability, although any such statements would be inappropriate and unmeaning as regards the details of the processes that take place inside the organism itself.

In any case it would appear that there is small chance of reducing these questions to direct dynamics ; we should rather regard Carnot's principle, which includes the law of uniformity of temperature and is the basis of the whole theory, as a property of statistical type confined to stable or permanent aggregations of matter. Thus no dynamical proof from molecular considerations could be regarded as valid unless it explicitly restricted the argument to permanent systems ; yet the conditions of permanency are unknown except in the simpler cases. The only mode of discussion that is yet possible is the method of dynamical statistics of molecules introduced by Maxwell. Now statistics is a method of arrangement rather than of demonstration. Every statistical argument requires to be verified by comparison with the facts, because it is of the essence of this method to take things as fortuitously distributed except in so far as we know the contrary ; and we simply may not know essential facts to the contrary. For example, if the interaction of the æther or other cause produces no influence to the contrary, the presumption would be that the kinetic energy acquired by a molecule is, on the average, equally distributed among its various independent modes of motion, whether vibrational or translational. Assuming this type of distribution to be once established in a gaseous system, the dynamics of Boltzmann and Maxwell show that it must be permanent. But its assumption in the first instance is a result rather of the absence than of the presence of knowledge of the circumstances, and can be accepted only so far as it agrees with the facts ; our knowledge of the facts of specific heat shows that it must be restricted to modes of motion that are homologous. In the words of Maxwell, when he first discovered in 1860, to his great surprise, that in a system of colliding rigid atoms the energy would always be equally divided between translatory and rotatory motions, it is only necessary to assume, in order to evade this unwelcome conclusion, that "something essential to the complete statement of the physical theory of molecular encounters must have hitherto escaped us."

Our survey thus tends to the result, that as regards the simple and uniform phenomena which involve activity of finite regions of the universal æther, theoretical physics can lay claim to constructive functions, and can build up a definite scheme ; but in the domain of matter the most that it can do is to accept the existence of such permanent molecular systems as present themselves to our notice, and fit together an outline plan of the more general and universal features in their activity. Our well-founded belief in the rationality of natural processes asserts the possibility of this, while admitting that the intimate details of atomic constitution are beyond our scrutiny and provide plenty of room for processes that transcend finite dynamical correlation.

ORGE S. ROBERTSON'S PRESIDENTIAL ESS TO THE GEOGRAPHICAL SECTION OF BRITISH ASSOCIATION AT BRADFORD.*

ness of the occasion led me to believe that the British elf was a very proper subject for such reflections as could ssed within the limits of an inaugural presidential address. ; with the important practical application of our science to of national life—political geography—I feel that perhaps explanation is necessary. Pure geography, with its placid nd its far-stretching outlook, combined sometimes with a evotion to the facts and conclusions of strict geographical s apt to incline many scientific minds to an admirable quiet- opolitanism—the cosmopolitanism of the cloistered college ture theatre. It perhaps also at times has a tendency to purely academic students a feeling of half disdain or irritability against those who love the science for its and social suggestiveness and elucidations. Thus there is a danger that geographers of high intellectual calibre, with sms entirely scholarly, may come to underrate nationality ook upon the world and mankind as the units, and upon and confederacies and amalgamations merely as specific s of the general type. We know that geography is often pon as the science of foreign countries more especially. Such confusion is undoubtedly less common than it was, yet it luences, unconsciously, the minds of many people. It is well forget this curious fact, and to point out, as if it required ising, that there is nothing foreign to geographical thought association of geography and patriotism, and that the home y is worthy of careful study, particularly when, as with us, me country is not Yorkshire, nor England, nor the United om, but the whole British Empire. Every true man loves his ountry the best in the world. To love mankind one must by loving individuals ; before attaining to true cosmopolitanism ust first be patriotic.

e British Empire is equal in size to four Europes, while its lation approximates four hundred millions. Although that may a somewhat grandiloquent method of description, it is a fairly ate statement of fact. Still more interesting to us is another —that outside of these islands we have some ten millions of e-skinned, English-speaking fellow-subjects. These islands are ely more than one-hundredth part of the whole empire, ugh we count as four-fifths of its white population ; of the total ber of the Queen's subjects we are, however, no more than a h. *British Empire* is somewhat of a misnomer, just as the North erican and Australian Colonies were never colonies at all in the sical sense of the word. For the colonies are not independent he mother country. An empire again really means a number subject peoples brought together, and at first held together, by ce. India is an empire, for instance. Happily, however, there no need now for any novel designation. The style *British pire* has become in time of stress a rallying cry for all the ueen's subjects, and the term has been sanctified by the noble ger devotion shown to her Majesty, both as a beloved and vene- ted constitutional sovereign, and as the common bond of unity tween those great self-governing daughter-nations which we in e past were accustomed to speak of as "our colonies." Con- erning the British Empire, and comparing it with other empires, ncient, recent, or now existing, its two most remarkable features re its prodigious and long-continued growth and the persistency of s power. It cannot to all seeming grow much larger, from lack of xpansive possibility. But it is unprofitable to predict. Every step which has been taken in the way of extension, particularly of late years, has been against the wishes and in almost passionate opposition to the views of large sections of the people. Yet the process of enlargement has gone on continually. In short, the British Empire, in spite of its seemingly reckless out- spread, its sometimes cloudy boundaries, its almost vague and appa- rently meaningless growth, is at the present day more braced together, more manageable, and more vigorous as a complete organi- sation than it was 60 years ago. The difference between its actual extent in the last year of the century and its size at the date of the Queen's accession can be estimated by a glance at a remarkable series of maps published in the "Statesman's Year Book for 1897," while since 1897, and at this instant, as we all know well, its mighty bulk is being still further increased.

The world as a whole has strangely contracted owing to a bewil- dering increase in lines of communication, to our more detailed geographical knowledge, to the formation of new harbours, the extension of railways, the increased speed and the increased number of steamships, and the greatly augmented carrying power of great sailing vessels built of steel. Then, hardly second in importance to these influences are the great land lines and the sea cables, the postal improvements, the telephones, and, perhaps, we may soon add, the proved commercial utility of wireless telegraphy.

* Abstract. Delivered September 6, 1900.

This universal time-diminution in verbal and personal contact has brought the colonies, our dependencies, protectorates, and our dependencies of dependencies, closer to each other and all of them nearer still to us. Measured by *time-distance*, which is the controller of the merchant and the cabinet minister just as much as of the soldier, the world has indeed wonderfully contracted, and with this lessening the dominions of the Queen have been rapidly consoli- dating. Nor is this powerful influence by any means exhausted. In the near future we may anticipate equally remarkable improve- ments of a like kind, especially in railways, telegraph lines and deep-sea cables, and in other scientific discoveries for transmitting man's messages through water, in the air, or perhaps by the vibra- tions of the earth. For us particularly, railway schemes of expansion must be mainly relied upon to open up and to connect distant parts of the empire. Our true and only trustworthy road of intercommu- nication between the heart of the empire and its limits must always be the sea. For general trade purposes, such as the convenience of business travellers, all Continental lines and all the great projected railways will be helpful, whatever nation controls them ; but our certain security is the sea, the sea which protects us, which has taught us to be an imperial people. If we ever forget that, there may be a calamitous awakening. We must not be persuaded to build—or at any rate to place reliance upon—land roads or railways through regions inhabited by tribes and peoples over whom we have not complete military as well as political control. Persian, Arabian, North African railway projects are happily rarely heard of now. As national enterprises they never were and never could be practicable, or otherwise than dangerous mistakes. In the future we shall remain a world-power only so long as we hold command of the sea in the fullest sense of the term, not merely by the force and efficiency of the fighting Navy, but by the excellence and the perfecting of our mercantile marine, by increasing its magnitude, carrying power, and speed, and by anxiously attending to its recruit- ment by British sailors.

And what has been said about railways applies, with obvious modifications, to telegraph lines and to maritime cables. The more general the extension of these, and the more numerous they become, the greater benefit will there be to this country in its double capacity as the greatest trader and the greatest carrier of merchandise in the world ; while the actual equivalent to a diminution of time-distance in travelling is to be found in the instantaneous verbal message which can be despatched to the most distant point of the empire. But we ought certainly to join all the shores of the Queen's dominions by sea cables completely controlled by British authority. To rely upon connection between our own cables through telegraph systems stretching across foreign countries, however friendly, or to permit the ends of these sentient nerves of the empire to emerge upon shores which might possibly become an enemy's country, is dangerous to the point of recklessness, that parent of disaster. As a melancholy instance of my meaning it is only necessary for us to remember the Pekin catastrophe—how we suffered from those dreadful intervals of dead silence, when we could not even communi- cate directly with our own naval officers at Taku, or with anyone beyond Shanghai, although we have in our possession a place of arms at Wei-hai-Wei, upon the Gulf of Pechili. It is obvious that we ought to have an all-British cable for pure strategic reasons as far as Wei-hai-Wei, our permanent military outpost on the mainland.

Now to give some suggestion of the increased facilities for carrying merchandise, for conveying passengers quickly about the world, and for the sending of messages to all parts of the earth, a few, a very few, salient facts may be quoted about ships—sailing ships and steam vessels—and about telegraphs and cables. In 1870 there were no more than 10 British sailing ships which exceeded or reached 2,000 tons burden. In 1892 the yards on the Clyde alone launched 46 steel sailing ships which averaged 2,000 tons each. In 1895 the number of large steel sailing ships being built in the United Kingdom was down to 23, and, speaking generally, it is inevitable that sailing vessels must give way to ocean steamships for most kinds of cargo—cattle, coals, wool, grain, oil, and everything else. . . . It is not too bold to predict that the Atlantic, from Queenstown to New York, will, before long, be steamed in less than four days. The question has now resolved itself simply into this—will it pay shipowners to burn so much coal as to ensure these rushing journeys before a cheaper substitute for coal is found ? We know that a torpedo-destroyer has been driven through the water at the rate of 43 miles an hour by the use of the turbo-motor instead of reciprocating engines. Consequently an enormous increase in the present speed of the great Atlantic liners is certain if the new system can be applied to large vessels. By such very swift steamers, and by the example they will set to all established and competing steamship companies, the journey to Canada and subsequently to all other parts of the Empire will be continually quickened, until predictions which would now sound extravagant will in a few years be simple everyday facts.

We must turn next to the subject of telegraphic communication, especially as it relates to the British Empire. The mazes of land- lines and of sea and ocean cables are too numerous and intricate to be described in detail. Also the general effect of this means of bringing

Digitized by Google

distant peoples together, and its transcendent importance for political, strategic, and trading purposes, need not be too much insisted upon in this place, so obvious must they be to everyone. Yet, great as has been its power and advantage in all of those directions in the past, it is certain that still greater development and still greater service to the world will follow in the future even from existing systems, not to speak of their certain and enormous possibilities of growth. In the celerity of the actual despatch of a message we need not ask for much improvement. Lightning speed will be probably sufficient for our go-ahead children of the twentieth century. But where we may expect and shall undoubtedly get increased success is in multiplied facilities for sending telegrams all over the earth and in widening their usefulness and convenience to all ranks and sections of the community. To obtain these necessary advantages there are two requisites—first a great and general cheapening of tariffs and, as a certain consequence of such reduced charges, a duplication or even a quadrupling of many of the present cables to prevent blocking; and, secondly, an indefinite extension of both lines and cables everywhere. Progress in submarine telegraphy undoubtedly means a lessening in the price of service and a firmer control by the State, as an obvious corollary to the large help to the companies already given by the general taxpayer, quite as much as it means those scientific inventions and scientific discoveries which the coming years have in store for us. At the present time the charges are far too high, ridiculously so as regards India, and the use of the great cables is therefore very often beyond the power of the small capitalist and the trader of the middle sort. Yet certain and early news is of supreme importance to large numbers of both classes. Its absence hampers or stops business, while its price is too severe a tax upon average profits. This fact has led to the invention of ingenious and elaborate codes. They might possibly have been devised in any case; but there is no doubt that messages by code would be certainly expanded so as to prevent all possible ambiguity if telegraphing to distant countries were not so costly. The spreading of land lines and sea cables about the earth has gone on rapidly since 1870; to the extent that those already completed would seem even to be in advance of their requirement, if that requirement were to be measured by their full employment. Nevertheless it is to be wished that new companies could be formed and new lines laid down to excite competition and thereby to cheapen rates; or else that our Government should step in and regulate charges over subsidised British lines. For the power of the great telegraph corporations by reason of their monetary resources enables them to overcome ordinary rivalry and to treat public opinion with indifference. A general cheapening of rates has constantly been followed by increased profits, earned by the resulting augmentation of traffic, but it needs an enterprising directorate to face the necessary initial expenditure, except under pressure. Boldness and foresight in finance are naturally less prominent features in the management of the great telegraph companies than contentment with a high rate of interest on invested capital. All their energy and watchfulness are employed to crush competition rather than to extend their activities indefinitely. Moreover, money making is their business, not Imperial statesmanship. If it were a question of the added security or the close coupling-up of the Empire (which are probably synonymous) on the one hand and a loss of profit (however splendid the dividends might still remain) on the other, we know what would be the result of their deliberations.

Important as are the sea cables for statesmen, for strategy, and for commerce, they are or will be equally important socially to keep up intimacy and swift intercourse between families half in Britain and half in India for instance, or between friends and relations in these islands and in the great colonies. They might be made to give the sensation almost of actual contact, of holding the hand of your friend, of speaking directly to his heart. It is this interchange of personal news and private wishes, quite as much as the profound political and commercial aspects of lightning communication with all parts of the empire, which will bind the empire in bonds stronger than steel, easy as affection, to hold it together with unassailable power. Consequently the health and strength of the empire depends very greatly upon a cheapening of telegraph charges. Doubtless a time will come when all our main cables of the first importance will be in the hands of Government, when they will only touch upon British territory, and when they will be all adequately protected from an enemy. Those are truly imperialistic and patriotic aspirations. But we must never forget the grand part in bringing together, within whispering distance as it were, the different parts of the world, and consequently of our world-wide empire, which has been taken in the past by such Napoleonic organisers as the late Sir John Pender. It is to him and to such men as he that we owe those splendid beginnings which by means of vital reflexes from the nerve centre of the empire have helped to fire our white fellow-subjects all over the globe with a loftier patriotism and with new, brave, and broader ideals of nationality.

It was coincident with the opening of the Suez Canal, in 1869, that the liveliest interest began to be taken in sea cables, and a master mind perceived their commercial possibilities. Before that time the success of the constructing companies had not been great. Sir John Pender then founded the famous Eastern Telegraph Co. by the amalgamation of four existing lines, which had together laid down 8,500 miles of sea cables, besides erecting land-lines also. A year later, in 1873, from three other companies he formed the Eastern Extension, Australasia and China Telegraph Co., which jointly possessed 5,200 miles of submarine lines. From that date the extension of electric communication to all parts of the earth, over wild as well as other civilised countries, and beneath the salt water, has only been equalled by their average remunerativeness. Now there are 175,000 miles of submerged cables alone, of which this country owns no less than 113,000 miles. The history of some of these cables is full of interest and might attract the delighted attention of the lover of picturesque romance no less than of the student of commercial geography. It also supplies suggestions and many facts, both to the physical geographer and to the student of seismic phenomena. Science has taught the companies to economise time, labour, and material in cable-laying operations, as well as how to improve the working instruments. Human ingenuity, business perception, and organising power have shown once more their startling possibilities when directed and controlled by cool, clear-eyed intelligence combined with general mental capacity. It is only necessary to re-affirm, for the reasons already given, the national, the imperial, the commonwealth requirement for cheap telegraphy, and the profound necessity there is, both strategically and politically, for complete government control by purchase, guarantee, or other equitable means over main cables which connect Great Britain with her daughter states, her Indian Empire, and her dependencies. Our communications with our own folk must be independent of private companies and completely independent of all foreign nations.

The general considerations which I have named might lead to the inference that actual geographical disadvantages, in trade competition for instance, may sometimes be conquered by man's resourcefulness and energy. Within obvious limitations that is certainly true. At places, as we know, the borderland between geography and many of the natural sciences is often vague and confusedly interlaced. So perhaps also with mechanical and economic science our boundaries at certain spots overlap. Quick steamers, far-reaching telegraph lines, and the piercing of isthmuses by ship canals may at the first glance appear outside the purview of the geographer. Yet from that particular aspect of geography which I have already spoken of as the science of distances we perceive how relevant they are, how worthy of study. Truly ours is a very catholic science. Our success as an empire will probably depend for its continuance upon a high level of national sagacity, watchfulness, and resource, to make up for certain disadvantages, as I think, of our geographical position since the cutting of the Suez Canal; and it will also depend upon the comprehensive and intelligent study of all branches of geography, not the least important of which to my view is the science of distances—the science of the merchant, the statesman, and the strategist.

REPORT OF THE NEW YORK RAILROAD COMMISSION ON BRAKE TESTS.*

The report of the competitive tests of street car brakes, held by the Board of Railroad Commissioners of the State of New York, has been issued, and contains a large amount of valuable information for electric railway men. The technical part of the report is made by Charles R. Barnes, electrical expert of the commission. It is very complete, and gives a history of the work from its beginning. On March 29, 1899, circulars were sent out inviting all makers of street car brakes to enter application for the tests, which were to take place on the tracks and cars of the Metropolitan Street Railway Co. of New York City. Twenty-six applications were filled out, and 25 were accepted. The results of tests were recorded by an automatic attachment, so that no complaint could be made as to unfair treatment by any of the contestants. This device was built and carefully calibrated by Mr. Barnes and Mr. W. A. Pierson, electrical engineer of the Metropolitan Street Railway Co. On each car 14 official speed records were taken—three at 8 miles an hour, three at 12 miles an hour, three at 15 miles an hour, three at 16 miles an hour, and two at 16 miles an hour with sand on the track. Air brakes were submitted to test by the following-named companies: Magann Air Brake Co., Christensen Engineering Co., Standard Air Brake Co., John E. Reyburn. Electric brakes were tested from the General Electric Co.; Columbia Electric Light and Brake Co.; Price, Darling & Co.; Electric Selector and Signal Co. Hand-power brakes were submitted by Sterling Supply and Manufacturing Co., M. H. Vogel, Sauvage Street Car Brake Co. Brakes classified as friction brakes were entered by the Peckham Motor Truck and Wheel Co., and the J. G. Brill Co. Track and wheel brakes tested were from the Devlin Street Car Brake Co., Philip Bach and Bernard

chlegel. A system of brake levers entered by the Safety Appliance o. was also tested.

The air brakes were all of the "straight-air" type, the differences eing in methods of compression and details of apparatus. Among lectric brakes the General Electric and Electric Selector were the nly ones that met the requirements of the test. The latter is a magnetic brake, attached to the regular brake rigging, and operated by the trolley current. Among hand-power brakes the Sterling is that used by the Metropolitan Street Railway Co. of New York City, and consists of gear wheels applied to the ordinary spindle, which multiply the force applied to the brake. The Vogel brake uses eccentric gear wheels on the ordinary brake spindle, so that the leverage is increased the nearer the brakes are set, while at first the slack is quickly taken up at a reduced leverage. The Sauvage brake system is constructed on the principle of a wedge working against a wheel. The Peckham brake was the brake known as the "Price Momentum," which originated on the Chicago City Railway. The Brill Company also presented a friction or momentum brake.

Table No. I., from the report, gives the averages of all the tests in feet and seconds required to stop the car at different speeds.

The comparative average stops at all speeds are shown in Table No. II.

It should be stated that the cars used were double truck, mounted on Brill maximum-traction trucks, with 30in. and 20in. wheels. The weight of the car in each case was 20,816lb., except the General Electric, which was 24,000lb.

Table No. III shows the result of a test made with a car equipped with the ordinary spindle hand brake, such as is in common use. This test was made on the same car (with same brake levers) that was tested with the Sterling brake, the results of which are given in Table No. IV. This test was made for comparing the efficiency of the ordinary brake now generally used with one of the improved brakes. The comparison was made with the Sterling brake because the change from the ordinary handle to the Sterling brake could be made more conveniently than any other.

Tests were also made to ascertain the comparative amount of force exerted by a motorman with the Sterling brake and the common brake. An 18in. hand-wheel was used in these tests. The average of all stops made by the Sterling brake, with this equipment, was 58·73ft., and the average of the power applied 77·08lb. With the common brake, the average stop was made in 56·87ft. and the average of the power applied 92·51b.

16	75	6	7·95	do.	12	75·41	8·07	80	Skid rear wheel, 6ft.

Clear, track dry.

Three stops were made from 15 miles an hour with a car equipped with the Electric Selector and Signal Co.'s electric brake on rails that had just been flooded. This test on the wet rail was made to compare it with the same equipment on a dry rail. The rails were wet by running a sprinkling cart over them three times. The result shows that the average stop on the wet rail was 71·73ft., and on the dry rail 60ft.

In conclusion, the board expresses its thanks to the officers of the Metropolitan Street Railway Co. for furnishing cars, tracks, and men free to the State for the tests and other valuable aid and co-operation.

The report of the commission is a valuable addition to technical literature, and is the first thorough investigation of street car braking ever made the results of which are public.

ELECTRIC SUPPLY MAINS CONTRACTS.

The following circular and Table of Conductors is being sent to Electrical Engineers by the Cable Makers' Association :—

September 13, 1900.

The terms and conditions in contracts for electric mains and details of conductors have varied so much in different specifications that, with a view to standardisation, the undermentioned cable makers have drawn up the following, which they suggest as a basis for tenders :—

1. Conductors.—The sizes and combinations of conductors shown on the accompanying Table to be adopted.

2. Guarantee.—If a guarantee be required for cables supplied and laid by the contractors, such guarantee to be in the form of an undertaking to make good any fault due to defective material or workmanship, and to be free for a period not exceeding twelve months after the cables are laid. In case it should be desired that this guarantee be extended beyond twelve months, an annual charge to be made.

In cases where cables are supplied by the contractor, but are not laid by him, the term of guarantee (if any) to date from the time of delivery of the cables.

Should the contractor be required under the guarantee to locate and repair any defect which may occur in the cables, a charge for such work to be made by the contractors in all cases where there is no proof that the defect was caused by bad material or workmanship,

A contract for maintenance when required to be considered as a separate matter from the guarantee and to be charged for accordingly.

3. Quantities.—In the case of a yearly supply of cable, the approximate quantities are to be stated, and the contractor shall not be called upon to deliver more than 25 per cent. in excess of these quantities, or less than 25 per cent. below them without special arrangements as to price being made.

4. Disputes.—The engineer's decision shall not be considered as final, but there shall be an arbitration clause.

5. Duplicates of Specifications.—Specifications shall be supplied in duplicate to all firms tendering.

6. Suspension of Works.—The purchaser shall pay to the contractor all reasonable expenses arising from suspension of works by the engineer, unless such suspension be due to any fault on the part of the contractor.

7. Payment.—In contracts for the supply and laying of cables, payment to be made on terms not less favourable to the contractor than 80 per cent. on monthly certificates, 10 per cent. on completion or putting to work (the completion or putting to work not to be dependent on any other contractor), the remaining 10 per cent. twelve months after completion.

In the case of cables supplied by the contractor but not laid by him, payment in full to be made within one month from date of engineer's certificate of each delivery.

8. Engineer's Certificates.—The engineer shall certify for payment within fourteen days of presentation of the account, and the purchaser shall make payment within one month from date of certificate.

In the event of there being any dispute as to the account, or any claim in connection with the work, the engineer may deduct from the account rendered such reasonable sum as may be necessary to cover the work in dispute; but the issuing of the certificate shall not be delayed in consequence.

Failing payments as specified in Clause 7, and this clause, the purchaser shall pay interest at the rate of not less than 5 per cent. per annum.

9. Tests.—Current for tests on site shall be supplied free to the contractor at the tension of the ordinary supply.

10. Extras.—The contractor shall not be called upon to supply without payment any materials or work not detailed in the specification.

11. Packages.—Where cables are supplied but not laid by the makers, the drums containing them shall be charged for, and allowed for in full when returned, carriage paid, in good condition within three months. If returned later, not more than two-thirds to be allowed.

The following cable makers have agreed to these terms and sizes of conductors to take effect on and after October 1st, 1900 : –

British Insulated Wire Co., Ltd.
Callender's Cable & Construction Co., Ltd.
Connolly Bros., Ltd.
W. T. Henley's Telegraph Works Co., Ltd.
Indiarubber, Guttapercha & Telegraph Works Co., Ltd.
Johnson & Phillips.
London Electric Wire Co., Ltd.
Siemens Bros. & Co., Ltd.
Telegraph Manufacturing Co., Ltd.
Western Electric Co.
W. T. Glover & Co., Ltd.

Standard Sizes of Conductors for Electric Supply Mains, to become operative on Oct. 1, 1900.

Nominal size of conduct'rs in square inches.	No. and diameter of strands.	Resistance in standard ohms per 1,000 yards.			Weight in lbs. per 1,000 yards.	
		Calculated.	Maximum allowable.	Maximum allowable for tinned wires.	Calculated.	Minimum allowable.

In concentric cables the outer conductors will have the resistance corresponding to the areas as given above.

MUNICIPAL, FOREIGN & GENERAL NOTES.

Aberdeen.—In connection with the accounts of the Aberdeen electricity station referred to in our last issue, it is of interest to note that the past year has been a record one in connection with electricity supply in this city both in regard to connections and output, and that there is every indication that the current year will be quite as satisfactory. One point in favour of the electricity undertaking is that gas has been raised 2d. per thousand, while it has been decided to keep the charge for electric current at the existing figure. The Gas and Electric Lighting committee recommend the Corporation to increase the salary of the city electrical engineer (Mr. J. Alex. Bell) from £300 to £350, rising by yearly increments to £500 per annum.

Alfreton.—The Council have formally decided to obtain a provisional electric lighting order.

Alnwick.—The Council have consented to the application of the Northern Counties Electricity Supply Co. for a provisional electric lighting order.

Ardrossan.—Proposals for the erection of electricity supply works, estimated to cost about £16,000, are before the Burgh Commissioners.

Asylum Lighting.—Prof. F. G. Baily has reported on the proposal to light the Fife and Kinross Asylum electrically. The initial capital outlay is estimated at £2,800, including buildings, and the annual maintenance charges are put at £400. Tenders are being invited for the work.

Ayr.—The annual report of the burgh electrical engineer (Mr. A. J. Fuller) was presented on Monday. During the past year 3½ miles of cable were laid and 72 new connections made, the number of consumers being now 372. The annual output had increased from 297,420 units to 425,639 units, or 43 per cent. The cost of production had been reduced from 2·03d. to 1·80d. per unit. The revenue amounted to £5,244, and after paying interest on capital (£1,530) there was a surplus of £235 to meet the sinking fund.

Bath.—The electric lighting mains are to be extended into the area of the Bath Rural District Council.

Birkenhead.—A special meeting of the Council was held on Wednesday to consider a report of the tramways sub-committee recommending the adoption of granite setts for the paving of the new electric tramway tracks. After considerable discussion the report was referred back.

Blairgowrie.—The proposed application by the North British Electric Supply Co. for a provisional order will be opposed by the Police Commission.

Brechin (N.B.).—The Angus Electric Lighting Co. has submitted a scheme for the electric lighting of the streets in which mains are to be laid. The company propose to substitute 16 c.p. incandescent electric lamps in place of the present lamps, and to provide lamps, connections, &c., the present lamp posts to be adapted for electric lighting. The company would also undertake the lighting and extinguishing of the lamps at the rate of £1 per 1,000 hours per lamp, which would be at the same rate as paid for gas lighting. The matter has been referred to a committee.

Digitized by Google

orne.—Negotiations have been opened with the Camborne lruth Tramway Co. for the supply of electric current for ighting.

iff.—At the meeting of the Electrical and Lighting committee ek a letter was read from Mr. W. H. Illingworth, mains tendent, which stated that when working in Charles-street one of the workmen received a severe shock. The accident sed by seizing a cable that was supposed to have been "dead." rer to questions, the chief engineer (Mr. N. Appelbee) said was on his holidays at the time, and had not had time to into the case. From the report it appeared to him that ingworth should have known that the cable was not "dead." quiry is to be held into the matter.

mbers of Commerce Congress.—At the Congress of British bers of Commerce, held in Paris last week, a motion by Mr. H. ard (Dover) proposing that arrangements should be made ut delay for connecting all lightships and isolated lighthouses he shore by means of wireless telegraphy was adopted. On otion of Mr. Hemelryk (Liverpool) the support of the Associa- was given to the Imperial Telegraphs Committee of the House mmons in their efforts to promote an inquiry into the whole ct. Mr. Plummer proposed that representations should be made e Postmaster-General on the great importance of underground s between the chief commercial towns and seaports, so that the serious losses arising from the interruption of the present system torms might be avoided. This course was approved.

leethorpes.—The District Council have resolved to take the essary steps to purchase and extend the electric lighting plant to erected by the Great Grimsby Tramways Co., as they propose to at the town electrically. The cost of the scheme is estimated at 0,000.

Devonport.—The Council have received sanction to the borrow- g of £67,947 for electric lighting purposes, being £15,250 for the urchase of land, repayable in 50 years, and £52,697 for generating ant, &c., payable in 25 years.

Dover.—It is stated that further powerful electric search-lights re to be erected on the heights to the east and west of the Admiralty Harbour, Dover. A power-house has already been constructed.

Driffield.—The application of the Northern Counties Electricity Supply Co. for a provisional order is to be opposed.

Dumfries (N.B.).—The Council has decided by 20 votes to 2 not to lease their provisional electric lighting order, but to establish municipal electricity works.

Electric Traction at Cape Breton.—The Cape Breton Tramway and Electric Co., which has a capital of £100,000, has decided to construct an electric railway in Sydney and suburbs. The advisability of continuing the line to Glace Bay is also under consideration.

Electric Traction in Holland.—A company, entitled the Zuid-Hollandsche Elektrische Spoorweg Maatschappij, has been formed for constructing an electric railway between Rotterdam and the Hague and Scheveningen. The authorised capital is 3,000,000fl. in ordinary shares and 4,000,000fl. in obligations. It is estimated that the cost of the line, which it is anticipated will be completed by 1903, will be 7,800,000fl. The whole of the plant will be supplied by the Siemens and Halske Aktiengesellschaft of Berlin.

Electric Tramways in Surrey.—The London United Tramways (Ltd) will apply next session for powers to make considerable extensions of its tramway system in the county of Surrey. The company propose to construct electric tramways from Hammersmith to Hampton Wick, via Putney-hill, Kingston-hill, and Kingston-bridge; from New Malden to Kingston; from the Kingston entrance of Richmond Park to Surbiton and Tolworth; from Surbiton to Long Ditton, Thames Ditton, and Esher; from Surbiton to Hook; and from Thames Ditton to Hampton Court. Richmond Council have referred the matter to their Tramways Committee for report.

Fraud.—A man, named William Neal, formerly a labourer in the employ of the National Telephone Co., was charged at Marlborough-street, London, last week, for obtaining money under fraudulent pretences. Neal appears to have described himself as still in the employ of the National Company, to have called upon a large number of telephone subscribers, and on the plea that the employés of the company were about to hold a "beanfeast" to have collected considerable sums of money on that account. The prisoner seemed to have experienced little difficulty in convincing subscribers of his bona fides, and the total amount collected during two months is known to have reached not less than £22. Neal was yesterday sentenced by Mr. Fenwick to one month's hard labour.

Hampstead (London.)—In the annual report of the electricity department, just issued, the total capital expenditure is given as £162,212. The total receipts for the past year amounted to £30,661, an increase of £6,283 on the previous year. The gross profit was £16,325, of which repayment of principal and interest absorbed £6,619. The total net profit since the commencement of the undertaking has been £20,586.

Hastings.—The work of constructing the electric tramways, powers for which were obtained last session, is about to be commenced.

Imports of Electrical Goods into the United Kingdom.—The value of electrical goods and apparatus imported into this country during August was £148,317, against £129,022 in the preceding month. The total for the eight months ended August 31 was £697,592.

Inverness.—A company has offered to take a transfer of the Council's provisional order and to reimburse all expenses incurred by the latter in connection with electric lighting matters, to erect electricity works and lay mains in the compulsory area, and to supply electric current for private lighting at 6d. and for public lighting at 3d. per unit. The Council would have the right to purchase at 14 years or any subsequent period of seven years. The offer has been referred to the Electric Lighting committee.

Irvine.—Bailie Kirkland has given notice of his intention to move: "That it be remitted to a small committee to secure a civil engineer who will consider the capabilities of our coalfields for electric light and traction"; and "That it be remitted to a small committee to secure a civil engineer who will consider the capabilities of the water power developed by the water in flow from the waterworks for electric light and traction."

Kirkcaldy.—The Council decided on Tuesday to adopt the recommendation of the Tramway and Electric Lighting committee in favour of carrying out their electric lighting and tramway scheme.

Lake District Electric Tramway Scheme.—At a public meeting at Windermere a resolution was unanimously passed against the proposal to construct an electric tramway from Windermere to Ambleside. A committee was appointed to organise opposition to the scheme.

Leigh.—Customers of the electric lighting department are to have the option of taking current at a uniform price of 5d. per unit or at the existing figures, viz., 7d. per unit for the first hour's maximum demand and 2½d. after. A tramways committee was appointed at Tuesday's meeting of the Council. The mayor (Ald. Fairclough) said that members were aware that the South Lancashire Tramways Co. had obtained their bill last session giving them power to construct a line from Lowton to Atherton through Leigh, and that the Council had agreed to that. They also obtained power to construct tramways to the outlying districts of Leigh, but the latter powers could not be exercised without the consent of the Council. It would never do to let the company come into the town and construct tramways right and left, as it would interfere with any scheme that the Council might deem it advisable to adopt. That being so, the Council could not block the company, but must do one of three things themselves—(1) either seek powers under a bill for the construction and the working of tramways in their own district, or (2) get an order for construction only, and then lease the lines, or (3) make arrangements with the company to construct those lines. The mayor, Ald. Greenough, Cowburn and Pennington, and Messrs. Shaw, Horrocks, Sims, Wood, and Speakman constitute the new committee.

Light Railways.—The Board of Trade have confirmed the following 1900 light railway orders: (1) South Staffordshire, authorising the construction of light railways in Wolverhampton, Wednesbury, Willenhall, Darlaston, Coseley, and Bilston; (2) Barnsley and District, for Barnsley, Worsborough and Monk Bretton; (3) Gateshead and District, for Gateshead and Whickham; (4) South Staffordshire (Extensions), for Bilston, Willenhall, and Coseley; (5) Bromsgrove, for Worcestershire (between Bromsgrove railway station and Lickey End); (6) Peterborough and District, for Peterborough and district.

The Blackburn Corporation have decided to grant facilities for the construction of a light (electric) railway between Blackburn, Whalley and Burnley, but reserve the right to purchase so much of the railway as is situate in Rishton in the event of the Blackburn borough being extended so as to include that district.

Llandaff.—The Council have resolved to apply for a provisional order.

Longton.—An inquiry was held here on Wednesday into the application of the Town Council to borrow money for electric lighting. The town clerk (Mr. G. C. Kent) appeared in support of the application, and said the provisional order was obtained in 1899, and the electricity works were being erected to the plans and specification of the consulting engineer (Mr. Robert Hammond). The staple trade in the town was the manufacture of china and earthenware, and apart altogether from the question of lighting business premises and residences, there was another important question. Recently there had been a considerable agitation with reference to lead poisoning and poisoning in other forms by the dust emanating from various processes, and a great amount of motive power was required for driving fans and other mechanical appliances. The Corporation anticipated a large demand for electric current for motive

Digitized by Google

r from those trades. It was proposed to adopt the continuous-nt three-wire system of distribution, and the approval of the l of Trade had already been received. There was no opposition.

idstone.—In a report just prepared by Mr. S. Sellon the cil are advised to apply for powers to construct electric tram- in the district. Mr. Sellon starts on the assumption that in own having a population of 30,000 electric tramways would be nerative, and he suggests the construction of four routes of a length of 4⅛ miles. The total cost of construction, equipment, ead work, feeders, generating station, and rolling stock is esti- at £40,721. The gross earning capacity would be fairly ented by £7,200 per annum at the outset, with a tendency to se. The working expenses would be about 50 per cent., which, allowing for depreciation and repairs, would leave a gross of £2,900, or a net profit for the first year of £457, after ting interest and sinking fund. The estimates provide for inute service.

ccclesfield.—The Council has received from time to time ations from companies for consent to provisional orders, but ision has yet been come to in the matter. At its last meeting neral Purposes committee discussed a communication from the ical Power-Distribution Co. announcing intention to apply for visional order and asking the Council's consent. An interview en representatives of the company and the Council (Mr. George appearing for the former) took place last week. The Council's lecision will be given later.

nchester and Liverpool Express Electric Railway.—The oters of this scheme, which was rejected by a Select Committee House of Commons (see *The Electrician*, May 18 and May 25), decided to renew their application for parliamentary powers session. Certain modifications have been made which, it is , will disarm opposition. The bill was thrown out principally objection of the Salford Corporation and the Dock Board, m intimation that if these could be removed the bill would a good chance of becoming law. The revised plans show a ion of the original line outside Liverpool so as not uch the land of the Dock Board, and the new it is stated, will be 20yds. shorter than the old. gards Salford, the viaduct cannot be dispensed with altogether, compromise is offered which the promoters think ought to e the objections of Salford. It is stated that the promotion ses this year amounted to nearly £10,000. On Thursday last gineers, Mr. F. B. Behr (the inventor) and Mr. Elliot Cooper consultation with the local directors to discuss alterations in &c. The local directors are Mr. W. Mather, M.P., Mr. Mac-, and Mr. T. Broadhurst, of Manchester, and Mr. D. ngham, of Liverpool.

nchester Municipal Technical School and School of Art.—labus, running into 360 pp., and interleaved with a large r of excellent illustrations of the buildings, interiors, &c., of nchester Technical School and School of Art is just issued Session 1900-1901 by Mr. John Heywood, Manchester and n, price 6d. (by post 9d.). The syllabus gives very full ulars of the numerous classes, and a careful perusal will show ending student how fully his requirements are met in this, the most completely equipped technical training establish- in the kingdom. Very full courses are provided for day and g classes. The session for evening students begins on Monday, 17, and that for day students on Tuesday, Sept. 18.

chant Venturers' Technical College.—We referred on of our last issue to the calendar issued for the session 901. We may add that amongst the recent improvements at lege are the provision of a much larger physical laboratory s equipment, an additional special laboratory for heat and nical physics, and the introduction of special courses of even- asses at reduced composition fees for electrical engineers, nical engineers, pattern makers, &c.

dlesbrough.—The consulting engineer (Mr. Robert Ham- has reported to the Electric Lighting committee that a ary supply of electric current will be available about October. ggested that a list of firms requiring temporary supply should pplied. As the supply was only to be temporary it would be lent upon one set of plant. Mr. Hammond further reported miles of mains suitable for arc lighting had been laid. He s that 30 or 40 arc lights be erected in the principal at a cost of from £1,200 to £1,500. Mr. Hammond's mendations were approved.

ssey (Surrey).—The East and West Molesey Council has l to engage an electrical expert to advise on the proposal of dson's Electricity Corporation to establish electricity works district.

mouth.—At the Council meeting last week the Electric g committee's report referred to a serious accident to the ce at the electricity generating station. On the morning of the 27th ult. the water suddenly ran short and it was found that the steam had forced a hole through the masonry under the sill of the weir and allowed the whole of the water to escape along another course. This had necessitated the dynamos being run by steam, entailing heavy expenditure, and the repair of the weir would probably cost several hundred pounds.

Municipal Telephony.—The question of the erection and equipment of a municipal telephone exchange occupied the attention of the members of the Portsmouth Council on Tuesday, and a formal resolution was passed authorising the Telephone committee on receiving applications from 400 intending subscribers, to apply to the Postmaster-General for a municipal telephone licence. It was announced that a number of applications had already been received.

Musselburgh.—The Council are anxious that the Drake and Gorham Electric Power and Traction Co., who this year obtained a provisional order to construct electric tramways in the district, should proceed with the work of construction, and at the Council meeting on Tuesday a letter was received from the promoters, in which, after expressing surprise at the Council's anxiety, stated that they had every intention of proceeding with the tramway and electric lighting scheme upon the earliest possible opportunity. It would, however, be necessary to mature their plans for financing that and other schemes, which they hoped would be conducted either in the coming autumn or the early spring of 1901.

Newport (Mon.).—The discussion by the Council of a proposal to erect an independent tramway power station has been postponed until after the November meeting.

Nottingham.—The City Council are erecting a refuse destructor at Eastcroft at a cost of about £21,000, and another at Radford costing £10,000. Ald. Mutch explained at the meeting on Monday that they anticipated that by utilising the heat which was generated by the destructor cells they would obtain from 450 H.P. to 500 H.P., which they would utilise in the generation of electric current. The value of the steam to the Electrical committee would be something like £4,000 per year.

Obituary.—We learn with regret of the death of Mr. John Robert Jefferies, a member of the well-known firm of Ransomes, Sims and Jefferies, of Ipswich. Mr. Jefferies had been ailing for some time, but his death was unexpected. He died on Wednesday morning, aged 60. Mr. Jefferies had been associated with the famous Orwell Works since 1856, when he joined the staff as a premium apprentice, and he had been one of the managing directors since the firm was converted into a limited liability company in 1884.

Pocklington (Yorks).—A report is being prepared for the District Council as to the relative cost of electric and gas lighting.

Presentation.—Last week, at Bolton, the employés of the electric lighting and tramway departments presented Mr. Arthur Ellis, electrical engineer and manager of the electric tramway system, with a solid silver tea and coffee service, on the occasion of his leaving Bolton to take up the position of electric tramway engineer to the Cardiff Corporation. In addition, members of the Tramway committee presented Mr. Ellis with a secretaire and fruit stand. Mr. Ellis leaves behind him at Bolton numerous friends who will watch his future advance in his profession with interest.

Rosario (Argentina).—Mr. H. S. Chappell has obtained a 40 years' concession from the municipality for establishing a telephone system in this city. The wires are to be underground, and the concessionaire is to pay the municipality 5 per cent of the gross receipts in lieu of all taxation.

Scarborough.—St. Nicholas Gardens are to be lighted by arc lamps.

Sheffield.—A portion of the Nether Edge depôt is to be set aside for the construction of new tramcars. At the Corporation meeting on Wednesday the chairman of the Tramways committee (Ald. Clegg) said he felt strongly that when the tramway system developed it would be necessary for the committee to be their own car builders and repairers. It was not intended to move very fast in construction, but they wanted power to construct more than one car, for the sake of cheapness. Their desire was to build three or four cars. There was room at Nether Edge, and the temporary workshop would not be costly.

The Electric Light committee recommend the following increases in salary: Mr. A. Cuthill (station superintendent) from £209 to £233, rising by annual increments of £35 to £283; Mr. A. Doxey (chief electrician) from £187. 4s. to £208, increasing by annual increments to £250. The increases to take effect from Jan. 1, and a three years' agreement to be entered into in each case. The salary of Mr. J. T. Ballard, mains superintendent, is to be advanced from £250 to £275 per annum, and on Dec. 31, 1901, from £275 to £300 per annum.

The Electric Lighting department has been asked to submit terms for the electric lighting of the sewage works.

Skipton.—A provisional electric lighting order is to be applied for by the Council.

Digitized by Google

South Africa.—Having got over the effects of the siege, the Town Council of Ladysmith are turning their attention to public improvements. At present the question of public lighting is under consideration, and tenders will shortly be invited. It is probable that electric lighting will be decided upon.

The *British and South African Export Gazette* announces that an expenditure of £50,000 is about to be incurred in the installation of additional generating plant at the Capetown tramway power station.

South Shields.—From Oct. 1 the charge for electric current is to be increased 1d. a unit for the first hour's maximum demand, making the price 7d. and 1d. per unit.

Southport.—The charge for electric current for power has been reduced from 6d. per unit for the first hour's maximum demand and 2d. afterwards to 4d. and 2d. respectively.

Swansea.—The Corporation have decided to formulate a scheme for wiring premises in the district on the "easy payment" system.

Swinton and Pendlebury.—A special meeting of the Council has been summoned for Oct. 8 to consider the purchase of the tramways in the district from the Manchester Carriage and Tramways Co. and to introduce electric traction.

Telegraph to the Klondike.—It is reported that direct telegraphic communication with Yukon will be opened on Oct. 1.

Telephone Communicaton with Mid-Wales.—Recently Col. Pryce-Jones, M.P., asked the Postmaster-General to afford further facilities for telephonic communication with Newtown, Welshpool, Aberystwith, and other towns in Mid-Wales, but in reply the Postmaster-General states that he has made inquiries locally, and judging from the replies received, there was little probability that sufficient support would be forthcoming from any of the towns or districts named to justify the expenditure involved. Col. Pryce-Jones now proposes to ascertain the minimum number of subscribers necessary to justify the extension of the system to Newtown.

Tiverton.—The consulting engineer (Mr. W. P. Adams) has presented a report on the proposal to erect electricity works, and three schemes are submitted for the consideration of the Lighting committee, viz., steam, gas, or turbine-driven plant. The water power scheme was the only one which would yield a profit from the outset, and the committee have decided, before reporting fully to the Council, to ascertain if this scheme is practicable. In the event of water power being employed, it would be necessary to obtain the sanction of the Board of Trade to the construction of a weir across the River Exe, and particulars have been submitted to the Board.

Truro.—The consulting engineer (Mr. F. H. Headley) is to report on the suitability of the Carvedras Smelting Works as a site for an electricity generating station.

Workhouse Lighting.—It appears from correspondence which has passed between the West Ham Guardians and the Local Government Board on the subject of the acceptance of certain tenders for the supply and erection of plant for the lighting by electricity of the West Ham Workhouse, that the Board is disposed to prefer an arrangement by which current is to be taken from the mains of the West Ham Town Council. It will be remembered that the tender of Messrs. Frank Suter & Co. for carrying out certain works in connection with the proposed lighting at the workhouse had been provisionally accepted by the Guardians. The Local Government Board point out that the estimated cost of the proposed installation based upon this provisionally accepted tender is 40 per cent. in excess of the original estimate, and the Board advise the Guardians to abandon the proposal to provide independent generating plant, and to either continue to use gas for lighting or, as above mentioned, to arrange with the Town Council for the supply of current from the mains. With regard to this alternative proposal the communication from the Board states:—

> The Board is advised that wherever there is a public supply of electricity available it is preferable for a Board of Guardians to use that supply for the workhouse rather than to themselves put down independent generating plant and apparatus, thereby incurring all the responsibility and cost of increased labour, repairs to machinery, consumption of coal, &c., besides the risk of requiring increased boiler power.

Worksop.—The four tenders received for electricity generating plant have been returned unopened, and it has been decided to invite fresh tenders.

Yeadon.—The Board of Trade are to be again invited to postpone the question of the revocation of the Yeadon provisional order, which was obtained in 1894. The Council are of opinion that, "owing to the depressed condition of trade and the undeveloped condition of the town, it is undesirable to put down electric lighting plant at present." Offers have been made to the Council by private companies to establish electricity works but the Council will not consent to electric lighting powers being obtained.

York.—Owing to the exceptional demand for current no more connections can be made until the new plant on order has been delivered. This is expected to be available in about a month's time.

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers, or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London:—

"The Art of Electrolytic Separation of Metals."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free. The author treats fully both the theoretical principles of the art of electrolytic separation of metals and the practical rules and details of technical application on a commercial scale. The work is adapted to the use of the manufacturer as well as the student.

"Electromagnetic Theory."—By Oliver Heaviside. *Vol. I.*, 12s. 6d. *Vol. II.*, 12s. 6d.

"Drum Armatures and Commutators," by Mr. F. Marten Weymouth, also ready. Price 7s. 6d., post free. Prospectus on application. This is a complete treatise on the theory and construction of drum winding, and of commutators for closed coil-armatures, together with a *résumé* of the principal points involved in their design, and an exposition of armature reactions and sparking.

"Electrical Engineering Formulæ," a pocket book, by Messrs. W. Geipel and H. M. Kilgour; price 7s. 6d.; by post, 7s. 9d.; abroad, 8s. *New Edition nearly ready.*

"Bibliography of X-Ray Literature and Research."—A valuable compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of general as well as special information bearing upon the whole subject of electrical discharge research. Edited by C. E. S. Phillips. Price 5s., post free.

"The Manufacture of Electric Light Carbons."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated, price 1s 6d.; post free, 1s. 9d. In this work the author gives useful hints as to the manufacture of electric light carbons, including the preparation of material, firing, saturating, and coring, together with a description and estimate of cost of the plant required.

"Localisation of Faults in Electric Light Mains."—By F. C. Raphael. Price 5s., post free. The book deals with the important subject of localising faults in electric light and power cables; and the various methods of insulation testing are here collected and discussed.

"Wireless Telegraphy: Signalling across Space without Wires by Electric Waves." A Review of the Work of Hertz and his Successors.—By Dr. O. J. Lodge, with a large number of illustrations, bringing this latest application of electrical science quite up to date. New and Enlarged Edition, 5s. nett. *Now ready.*

"The Centenary of the Electric Current, 1799-1899."—By Dr. J. A. Fleming. Price, paper covers, 1s. net, post free 1s. 3d.; strong cloth, s. 6d., post free.

"The Manufacture of Carbons for all Electrical Purposes."—by Francis Jehl. 10s. 6d., post free. This is a practical handbook, giving a complete description of the art of making carbons for electric lighting, electrodes, &c., with particulars of the various gas generators and furnaces used in carbonising. The work also contains particulars of the cost, &c. of erecting and working carbon works, and plans of a model factory.

"Motive Power and Gearing for Electrical Machinery."—By E. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free. In this comprehensive work an account is given of the scientific principles and modern practice in the use of engines for dynamo driving, not only for isolated power plants, but also for public electric lighting and power stations. The various forms of gearing in the power station and for electric motors are also dealt with; and the book contains, in addition, numerous tables giving exact data of the equipment and working of electric power stations.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. *New and Cheaper Edition*, 6s., post free.

"The Students' Guide to Submarine Cable Testing."—A new edition of this book, by Messrs. H. K. C. Fisher and J. C. H. Darby, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated.

"The Incandescent Lamp and its Manufacture."—By Gilbert S. Ram. Price 7s. 6d., post free. The principles underlying the manufacture of the incandescent lamp are carefully and fully dealt with in this volume.

"Magnetic Induction in Iron and other Metals."—By Prof. J. A. Ewing. Price 10s. 6d. net. *New Edition (Third) now ready.*

"Electric Motive Power," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. Price 10s. 6d., post free; abroad, 11s.

"Electrical Testing for Telegraph Engineers."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. Demy 8vo, fully illustrated. 10s. 6d., post free.

"Submarine Cable-Laying and Repairing.—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d. This work gives a detailed technical summary of modern practice in manufacturing, laying, testing, and repairing submarine telegraph cables.

"The Alternate Current Transformer."—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. Vol. I.—*New Edition.* Price 12s. 6d., post free, Vol. II., price 12s. 6d., post free, is also ready.

"Armature Winding of Electric Machines."—By H. F. Parshall and H. M. Hobart. This work has been compiled from notes made by Mr. Parshall in his capacity as Chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables, 30s. post free.

Digitized by Google

"TEMPERATURE COEFFICIENTS OF 'CONDUCTIVITY' COPPER." Compiled by Messrs. Clark, Forde and Taylor, consulting engineers. Strongly bound in cloth, 2s. 6d. net. Also a Sheet Table of Log. Reciprocals of Coefficients for Copper Resistances at different temperatures from 32°F. to 84·9°F. Printed on strong cardboard, 6d. net.

"LABORATORY NOTES AND FORMS."—We have ready a set of 40 Elementary and Advanced Exercises for use with Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of the series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net; in sets of any three, 1s. net; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net; or in handy portfolio, price 12s. net; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnics and other Science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper, and with less space for tabulated records, are issued at half the price of the original set.

"THE POTENTIOMETER AND ITS ADJUNCTS": A Universal System of Electrical Measurement.—By W. C. Fisher. Fully illustrated. Price 6s., post free.

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office no later than first post Thursday morning. New Catalogues, Price Lists and similar matter should be sent early in the week.]

TENDERS INVITED.

Walthamstow District Council invite tenders for the supply and erection of electric lighting plant and apparatus, including gas plant, gas engines, dynamos, switchboard, boosters, balancer and measuring instruments. Specifications may be obtained from the consulting engineer (Mr. James Enright), 47, Victoria-street, London, S.W., after Sept. 4. Further particulars are given in an advertisement, and tenders must be delivered to the town clerk (Mr. E. J. Gowen), Town Hall, Walthamstow, by 5 p.m. Sept. 25.

Hackney (London) Electric Lighting committee invite tenders for electricity supply mains. Specifications may be obtained from the consulting engineer (Mr. Robert Hammond), 64, Victoria-street, Westminster, S.W., after 12th inst., and further particulars are given in an advertisement. Tenders must be delivered to the vestry clerk (Mr. George Grocott), Town Hall, Hackney, by 5 p.m. on Oct. 3.

Devonport Corporation invite tenders for two vertical engines, two 300kw. generators, balancer, battery, booster and motor, switchboard for lighting and traction, storage battery, and a 10-ton travelling crane. An advertisement gives further particulars, and specifications may be obtained from the borough electrical engineer (Mr. Charles Furness), Technical School, Devonport. Tenders to town clerk (Mr. A. B. Pilling), Municipal-buildings, Ker-street, Plymouth, by 5 p.m. 26th inst.

Sheffield Corporation invite tenders for: (*a*) Two 600kw. two-phase steam alternators and exciters, and (*b*) alteration of present single-phase plant to two-phase. An advertisement gives further particulars, and specifications can be obtained from the chief engineer and manager of the electric supply department (Mr. S. E. Fedden), Commercial-street, Sheffield, where tenders must be delivered by Oct. 6.

Fulham (London) Vestry invite tenders for the supply and erection of coal handling plant at their electricity works. Specifications may be obtained at the office of the consulting engineer (Mr. F. H. Medhurst), and tenders must be delivered at the offices of the clerk (Mr. W. J. H. Denselow), Town Hall, Walham Green, S.W., by 6 p.m. of 25th inst. An advertisement contains further particulars.

Salford Electric Light committee invite tenders for the supply and delivery of seven iron transformer chambers. Specification may be obtained from the borough electrical engineer *pro tem.* (Mr. F. A. Wilkinson), and tenders (addressed to chairman of committee) must be delivered to the town clerk (Mr. L. C. Evans), Town Hall, Salford, by 10 a.m. 24th inst. See advertisement.

Salford Corporation also invite tenders for two cast-iron water storage tanks for their Strawberry-road electricity works. Tenders to town clerk by 17th inst.

London County Council invite tenders for mains for the electric lighting of Victoria Embankment and Westminster Bridge. Tenders to clerk, Spring Gardens, before noon Sept. 24.

London County Council Asylums committee invite tenders for boilers, engines, dynamos, &c., at Horton Estate, Epsom, Surrey. Tenders to committee, 6, Waterloo-place, S.W., by 10 a.m. Sept. 22.

Dublin Corporation also invite tenders for supply and erection of power machinery at Ringsend, including pumping engines and pumps, boilers, electric motors and pumps. Tenders to town clerk by noon Oct. 3.

Dublin Electric Lighting committee invite tenders for electricity supply mains and accessories. Tenders to town clerk, City Hall, Dublin, by 4 p.m. Oct. 4.

Eastbourne Corporation invite tenders for the supply and erection of water-tube boilers, with fittings, feed pumps, &c.; 400kw. steam alternator, with exciter (vertical enclosed high-speed engine); and main switchboard and connections. Tenders to town clerk by noon Oct. 4.

Aberdeen Electric Lighting committee invite tenders for two 200kw. direct-coupled continuous-current generators and one 120kw. balancing set; also for one 420kw. direct-coupled continuous generator. Willans engines in both cases. Tenders to city electrical engineer by Sept. 29.

Manchester Tramways committee invite tenders for two steel boilers, cast-iron pipes, rubber rings, bolts and nuts, steel stanchions, &c., and 100 car trucks. Tenders (addressed chairman of committee), to the town clerk by 18th inst.

The Vestry of St. John, *Hampstead* (London), invite tenders for eight dry-back marine boilers, steam and water pipes, feed pumps, &c. Tenders to vestry clerk, Vestry Hall, Hampstead, N.W., by 4 p.m. Sept. 27.

Tenders are invited for wiring the *Suffolk* County Asylum, Melton, for the electric light. Tenders to Mr. A. T. Cobbold, County Hall, Ipswich, by Oct. 5.

Sunderland Corporation invite tenders for triple expansion high-speed direct-current steam dynamos, Lancashire boilers, and feed pumps. Tenders to town clerk by noon Sept. 21.

Dundalk District Council invite offers for the transfer of their provisional electric lighting order. Tenders to town clerk, Town Hall, Dundalk, before 1 p.m. Sept. 18.

Brighton Corporation invite tenders for 25 electric motor-car bodies, trucks, and electric-motor equipments, and also for steel girder tramway rails, fishplates, and joints. Tenders by Oct. 1.

Hull Electric Lighting committee invite tenders for steam and water pipes, feed-pumps, &c. Tenders (addressed chairman of committee) to town clerk's office by noon Sept. 27.

Tenders are invited for wiring *Wrexham* Corporation baths. Particulars from Messrs. Trentham and Peers, 96, Deansgate, Manchester, before 15th inst.

Middleton Town Council require tenders for erecting electricity station buildings. Tenders to town clerk by Oct. 11.

Glasgow Corporation invite tenders for the power station piping required at Pinkston. Tenders to town clerk by 5 p.m. Sept. 28.

Tunbridge Wells Corporation invite tenders for high and low-tension cables. Tenders to town clerk by Sept. 29.

Whitehaven Corporation invite tenders for a switchboard. Tenders by Oct. 13.

Rathmines and Rathgar (Dublin) Council require tenders for electric lighting stores, coal, &c. Tenders by 24th inst.

Tenders are invited for erecting and equipping a telephone exchange in *Santiago de Compostella* (Spain). Tenders to the Civil Administration of Corunna Province, or to the Registro del Direccion Generale de Correos y Telégrafos, Madrid, by 13th prox.

Tenders are invited for the electric lighting of *Azuaga* (Spain). The lighting is to be effected by 10 c.p. or 16 c.p. incandescent lamps, and the equivalent of about 3,000 will be required. Tenders by 11th prox.

Cienfuegos (Cuba) Municipal Council invite tenders for public electric lighting. Tenders to secretary by Oct. 26.

The Director-General of Works and Communications of the Brazilian Ministry of Industry, *Rio de Janeiro*, invite tenders for the supply and erection of electric (or hydraulic) cranes on the new quay at Recife.

TENDERS RECEIVED AND ACCEPTED.

Portsmouth Corporation have received the following tenders for the complete equipment of the proposed tramway power station:—

Dick, Kerr & Co. (*accepted*)	£29,656	0	0	Brit. W'stingh'use Co.	£29,390	0	0
Elec. Constructn. Co.	30,262	0	0	Brush Co.	29,351	10	0
Siemens Bros. & Co.	29,858	0	0	Brit. Schuckert Co.	29,130	0	0
R. W. Blackwell & Co.	29,568	17	0	Combe, Barbour & Combe	27,137	12	6

The special sub-committee, to whom these tenders were referred, reported that only three firms (Messrs. R. W. Blackwell & Co., Dick, Kerr & Co., and the Electric Construction Co.) would complete the work before next summer, and they submitted for consideration the alternative offer of R. W. Blackwell & Co. on engines of British make (made by Yates and Thom) for £29,875. 17s., and the offer of

Digitized by Google

Messrs. Dick, Kerr & Co. for £29,656. The first-named firm would complete the work in eight months, while Messrs. Dick, Kerr & Co. would undertake to run one or two sets in six to seven months, and complete the whole in nine months. The offer of Messrs. Blackwell was for American electrical apparatus. The generators varied slightly from specification in having a lower efficiency. Messrs. Dick, Kerr & Co.'s tender provided for British-made plant, &c., throughout, and the whole of the apparatus was entirely in accordance with specification. This tender was also superior to Messrs. Blackwell's in other respects, notably with regard to the pipe work. Both were experienced firms, and practically agreed to the conditions of contract, excepting for an objection on the part of Messrs. Blackwell to clauses 15 and 24. They therefore recommended the acceptance of the tender of Messrs. Dick, Kerr & Co., and this recommendation was adopted.

The contract for the erection of the station building has been let to Mr. J. W. Perkins at £10,515. 8s.

In our last issue we announced that the tender of E. Lace & Son had been recommended for acceptance by the Cardiff Electric Light committee for the supply of sundry pipes, feed water heater, &c, for the electricity works at £1,379. This recommendation has been adopted by the Corporation, and we give below a list of the tenders received :—

E. Lace & Son (*accepted*)	£1,379 0 0	J. Williams & Son	£1,760 0 0
E. Danks & Co.	2,500 7 6	Babcock & Wilcox	1,525 0 0
Edwards & Barnes	2,159 0 0	Aiton & Co.	1,442 0 0
D. B. McCallum	1,953 0 0	Crompton & Co.	1,173 0 0

The City of London Guardians have received the following tenders for wiring the Board's offices, 61, Bartholomew-close, E.C. :—

Newsome, Pinching & Co. (*accepted*)	£430 0	E. H. Leaf	£545 10
Wm. Heath	624 0	J. O. Grant	542 7

Messrs. Richard Johnson & Nephew submitted the lowest tender to the Roumanian Post and Telegraph authorities, Budapest, for the supply of 40 tons of galvanised steel wire, 2mm. diameter, quoting 699·8fr. per metrical ton.

Aberdeen Corporation have accepted the tender of Messrs. Macartney, McElroy & Co. for steel poles, bases and brackets, for extensions of the overhead tramway system. Tenders were also submitted by Messrs. Robt. W. Blackwell & Co., McDowall, Steven & Co., Lowdon Bros. & Co., J. Russell & Sons, and the Walsall Electrical Co.

The Hart Accumulator Co. have secured the contract for the supply of the storage battery required by the Nuneaton and Chilvers Coton Council for the extension of their electricity supply works.

Middlesbrough Town Council have accepted the tender of Messrs. Tadsall and Smith for wiring the electricity works at £231. 15s.

Belfast Electric committee have accepted the tender of Messrs. Edwards and Barnes for feed-water heaters for the electricity supply station.

Southport Corporation have accepted the tender of Messrs. S. Z. de Ferranti (Ltd.) for a rectifier and switchboard at £400, and that of Messrs. Gwynne & Co. for motors and pumps at £710.

Morecambe Council have accepted the tender of Messrs. C. A. Parsons & Co. for condensing plant for the electricity works at £490. The tender of Messrs. E. Green & Son has also been accepted for additional economiser pipes.

APPOINTMENTS VACANT AND FILLED.

Crewe Corporation require the services of an electrical engineer for their new electric lighting and traction works. Salary £200 per annum. Applications to be sent in to the town clerk (Mr. Frederick Cooke) before 19th inst. See advertisement.

A shift engineer is required for the Rathmines electricity works. An advertisement gives further particulars, and applications must be sent in to the resident engineer (Mr. G. F. Pilditch), electricity works, Rathmines, Co. Dublin, by Monday, 24th inst.

Brighton Corporation require a junior assistant in their meter and testing room. Applications to manager, electricity works, North-road, Brighton. See advertisement.

Birmingham Small Arms Co. require an assistant electrician. See advertisement.

An assistant electrical engineer and fitter is required for the City of London Asylum, near Dartford, Kent. Applications to medical superintendent. See advertisement.

An engineer to look after electric lighting plant is required for the Park Fever Hospital, Hither Green, S.E. Applications to Metropolitan Asylums Board, London, E.C., by 24th inst.

Eccles Corporation require a consulting electrical engineer to advise on the extension of the electricity supply undertaking. Applications to town clerk by 17th inst.

Lowestoft Corporation invite applications for the position of resident electrical engineer. Applications to town clerk before 21st inst.

A lecturer and demonstrator in physics is required at University College, Nottingham. Applications to secretary by 25th inst.

There is a vacancy for a pupil at the Rathmines electricity works. Particulars from the resident engineer (Mr. G. F. Pilditch).

Mr. A. J. Margetson, associate of the Merchant Venturers' Technical College, has been appointed assistant in the Mechanical Engineering Department of that institution. Mr. Margetson entered the electrical engineering department of the college as a City of Bristol senior scholar, and completed his course of study in 1894. Since then he has been employed in the works of the Bristol Wagon and Carriage Co.

BUSINESS NOTICES.

We are asked to state that the business relations between Messrs. Pritchetts and Gold and Messrs. Venner & Co., by which the latter firm have acted as sole selling agents for the Pritchett accumulator, have been dissolved by mutual consent. Firms who have previously dealt with Messrs. Venner & Co. for Pritchett accumulators are requested in future to communicate direct with Messrs. Pritchetts and Gold.

Messrs. Ward and Goldstone have taken more extensive premises at 45, Dutton-street, Strangeways, Manchester.

Messrs. Everett, Edgcumbe & Co. inform us that they have taken over the instrument making business of the Edwards Electrical Co., Ltd, of Bow, London, E. Some advance sheets of the new catalogue now in preparation are forwarded, and illustrate and describe "Harrison" direct-coupled recording voltmeters of several types, dial ammeters for alternating or direct current, charge and discharge ammeters, "Swinburne" wattmeters, &c. Copies of these advance sheets can be obtained on application from the offices, 22, Charterhouse-square, London, E.C.

The British Thomson-Houston Co. have opened a branch office in Manchester at Trevelyan-buildings, Corporation-street, where local inquiries should be sent.

BANKRUPTCIES, LIQUIDATIONS, &c.

Claims against E. J. Paterson and C. F. Cooper (trading as Paterson and Cooper), European Works, Pownall-road, Dalston, and 3, Prince's Mansions, Victoria-street, London, and 137, West Regent-street, Glasgow, must be in by 22nd inst. Mr. E. C. Moore, 3, Crosby-square, London, E.C., in trustee.

F. L. L. Lindsay, electrical and mechanical engineer, Gorphwysfa, Llandegfan, Anglesey (lately trading at 216, High-street, Bangor), has been adjudicated bankrupt. The first meeting of creditors will take place on 18th inst., at the Ship Hotel, Bangor, and the public examination on Oct. 4 at the Magistrates' Room, Bangor.

R. Foster and W. Baker (trading as Robert Foster & Co., and as the Nelson Electrical Engineering Company, at Burnley and Nelson, Lancs.) have been adjudicated bankrupts.

Easton, Anderson and Goolden (Ltd.).—A meeting of the shareholders and creditors of this company was held at the Guildhall Tavern, London, on Wednesday, presided over by Mr. Peat, official liquidator.

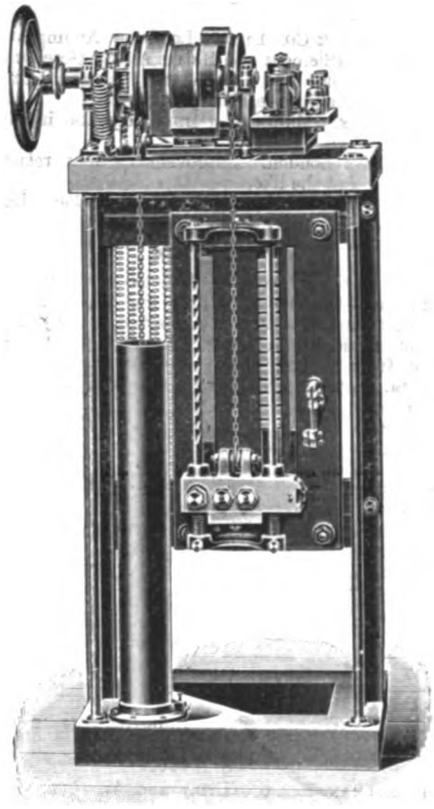
The CHAIRMAN said he was authorised in April, 1899, to dispose of the business as a going concern, but up to December last he had not succeeded in doing so, although several tenders had been made, with resulting negotiations involving much correspondence, but nothing definite had accrued. The firm was still going on and carrying out contracts given by the Admiralty, and their trade *clientèle* was, in fact, of the highest character. There had been a good deal of litigation in connection with the firm's contracts, but on the whole much very satisfactory—indeed, profitable—business had been done, and they had a large amount of work still to do. No accounts had been made up from last December to the present month, and he could not say anything definite on that subject. They had been in litigation over one matter, and judgment was given in their favour, but an appeal was still *sub judice*, so he could say nothing as to that. The creditors had been brought together solely because Mr. Hooley had been unsuccessful in floating the company, and a claim was pending against the trustees of Mr. Hooley's estate. They had been met in a very fair spirit. Since the last meeting attempts had been made to sell the business, and the negotiations up to the present time had been embodied in the form of an agreement, which the Court had sanctioned, and this meeting of debenture-holders, shareholders and creditors had been called together to confirm the agreement. In effect the agreement provided, as was set out in the circular calling the meeting, for the purchase of the entire concern for £252,000—£27,000 in cash, £150,000 debentures, £30,000 preference shares, and £45,000 ordinary shares. He (Mr. Peat) had advanced £10,000 to continue the business, and £17,000 would be applied to pay arrears of interest. This disposes of the £27,000 in cash they were to receive, and the debenture stock to be received would go to satisfy the existing debenture shareholders. Mr. Wilson had agreed to take new preference shares in lieu of his present holding. The 45,000 ordinary shares were to be retained under the control of the liquidator for two years, and the proceeds arising from them as the proposed new company progressed would go to the creditors. The dividend on the old estate was about £10,000. He had already received about £5,000, and there was cash at bank £3,000. They anticipated about

Digitized by Google

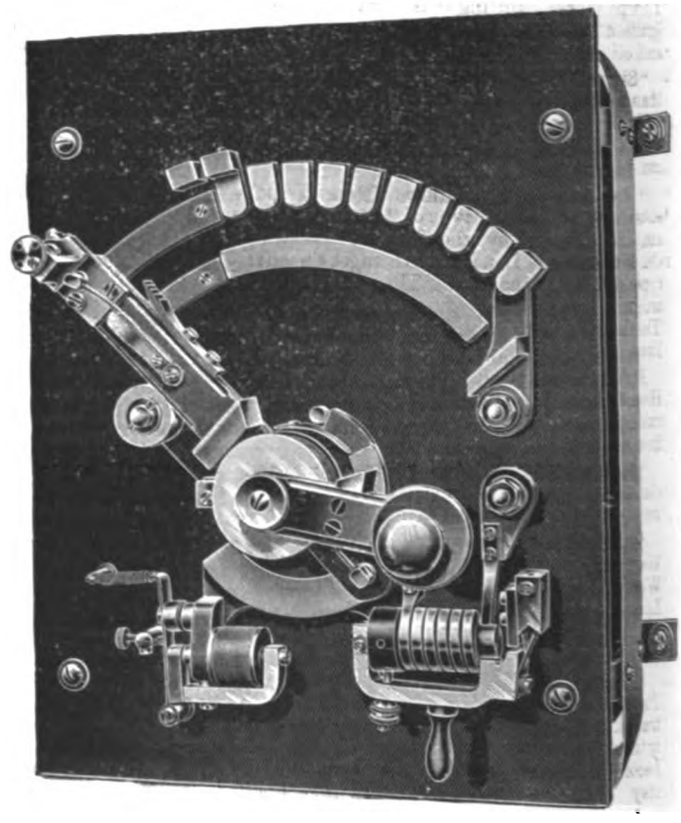
£3,000 as the result of the pending lawsuit to which he had referred. The cash assets of the company he estimated at between £10,000 and £15,000 plus the £3,000 from the lawsuit and £45,000 in ordinary shares. Against this the claims of creditors amounted to £59,743, or, after certain reductions had been made, to, say, £56,000. No promotion was being paid to anyone in connection with the new company, but Mr. Wilson was to receive £2,500 in ordinary shares in consideration of making over certain valuable patents in connection with a new machine. The new company was practically a reconstruction plus an amalgamation which Mr. Wilson was hoping to bring about in a certain direction. This would involve the bringing of £50,000 fresh capital into the firm and the creation of a fresh debenture stock, but that was a question of the future, and more could not be said thereon at present.

After Mr. Wilson had made a few remarks concerning the new machine, a resolution that the meeting, having heard the statement of affairs, approve the sale of the business set out in the agreement mentioned, and authorised the receiver to see same carried into effect, was carried unanimously.

Patent Automatic Switches.—We illustrate below the A and B types of automatic switch manufactured by the Electrical Transmission Co., Albert Works, Beavor-lane, Hammersmith, London, under the patents of Mr. Walter F. Jones, the manager of the company. For the A type it is claimed that it is practically impossible for an unskilled operator to damage either the motor or the switch, as it switches on automatically at a slow speed out of the operator's control after the motor-field magnets are well excited. It switches off automatically if the motor is overloaded, or if the current exceed the given quantity, or if supply fails. When the case is on there is nothing outside but the operating hand wheel, the whole of the mechanism being enclosed. In general practice, the switch is the same as the B type, the arrangement of the parts being, however, different. The chief claim made for the A type over the B type is that it takes the starting-up entirely out of the operator's control and switches on at the speed for which it is adjusted. The switch-arm stops when full on each contact, and proceeds with a "quick make" to the next when cutting out the resistance switching-on, thus avoiding a fault which has prevented the satisfactory continuous working of many other slow-moving switches. The switch operation is performed as under: When starting up the operator winds up a heavy weight in a dash-pot by means of a spring bolt, and when fully wound the hand wheel sheers out of engagement with the weight by compressing the spring bolt. This locks the hand wheel and prevents further forward movement. The weight then descends into the dash-pot, drawing the switch-arm over the contacts, and the step-by-step motion is secured by a spring detent which acts at each contact. Moving the hand wheel backwards, the switch-off causes the short-circuiting of the clutch and releases the switch-arm. The B switch, on the other hand, cannot be switched on until the motor field magnets are well excited. It automatically switches off if the operator attempts to switch on too quickly, if the current exceeds a given amount, or if supply fail. The chief novel feature of this switch is that the handle is not directly attached to the switch-arm, but is held to it by electro-magnetic means when the conditions are suitable. The switch-arm and handle lever are of iron, and have pole-pieces attached extending across the face of a coil mounted to surround the iron spindle of the switch, and together they constitute an electro-magnetic clutch. The switch also has a temporary contact (shown just above the clutch coil in the illustration), a non-sparking arrangement (shown at the bottom left in the illustration), and a maximum cutout and hand switching-off handle (shown at the bottom right in the illustration). The illustration shows the switch in the "off" position. The action of switching-on is as follows: The handle is brought towards the switch-arm, so as to bring the pole-pieces together; this causes the circuit at the temporary contact to energise the clutch coil and also excite the motor magnets, as the clutch coil is in series with the motor field-magnet coils. It is then necessary to pause for a short period, depending on the size of the motor, until the current in the field magnets has risen to about its proper amount, as otherwise the clutch will not be sufficiently powerful for the switch handle to draw the switch-arm against the spring which has brought it to the "off" position. The switch-arm can then be drawn slowly from contact to contact until the full "on" position is reached, when the switch handle is held by a spring detent. The gradual rise of the current in the field magnets of a motor, especially those of large size, can be easily noted by placing an ammeter in the circuit, and where it is not taken into account serious excessive flushing of current with damage to switch contacts and sparking at the motor brushes results through the only partial excitation of the magnets. Should the operator switch on too fast the maximum cutout acts, short-circuiting the clutch coil, so releasing the switch-arm from the handle, when it springs back to the "off" position, inserting the resistances as it does so. The object of the "non-sparking" arrangement is to temporarily close the circuit while the switch-arm is travelling to the first contact of the switch, when it is cut out of circuit. Open-type switches are provided in all cases with wire guards, so that the action of the apparatus cannot be interfered with, and the maximum cutout handles are arranged so that they cannot be held down.



A type Switch (on special frame).



B type Switch.

Electrical Engineering Business for Sale.—The business of P. C. Middleton & Co. (Ltd.), electric light and power engineers, of Aberdeen, Edinburgh, Inverness, &c., is for sale as a going concern. Further particulars are given in an advertisement. The business includes the electricity supply plant and mains at Cults, Aberdeen. The liquidators offer the business for sale as a whole, but are prepared to consider separate tenders for the various branches. Offers to either Mr. W. R. Reid, advocate, 46A, Union-street, Aberdeen, or to Mr. S. Easton Simmers, C.A., 58, Bath-street, Glasgow, joint liquidators; or to their law agents, Messrs. Wilsone and Duffus, advocates, 146, Union-street, Aberdeen, who will supply all further information.

Engineering Works for Sale.—Our advertisement columns contain particulars of engineering works in the city of Dublin which are offered for sale by tender as a going concern owing to the death of the late proprietor. The works are centrally situated and have a suitable set of offices, pattern shop, machine shop and foundry, and smith's shop, together with a number of tools which are all of modern type, many of them being new. Tenders are to be addressed to Mr. A. Basil Wilson, M.I.C.E., Maryville, Malone, Belfast, from whom further particulars can be obtained.

For Sale.—In an advertisement an English patent of an electromotor is offered for sale by Mr. P. F. C. Iserloth, of Hamburg.

"Sunbeam" Lamps—A useful little pocket price list of "Sunbeam" lamps, lampholders, &c., is to hand, of which copies can be obtained by the trade on application to the company's office, Park-road, Gateshead-on-Tyne, or at the London offices, 141, Fenchurch-street, E.C., and at the company's numerous depôts.

Ignition Batteries.—Messrs. C. A. Vandervell & Co., of Thorpe Works, Notting Hill, London, W., issue a handy list of electric ignition batteries for motor cars, cycles, &c., and for stationary gas and oil engines.

"Sirius" Exhaust Steam Injector.—Messrs. Holden and Brooke, Manchester, issue a neat pamphlet of testimonials from users of the "Sirius" exhaust steam injector manufactured by the firm, particulars of which are published in pocket list No. 25. Both publications can be obtained on application.

"Stewart" Arc Lamps (New Type).—Price lists are now obtainable of the new type of "Stewart" alternating-current enclosed arc lamp made by the Stewart Electrical Syndicate, 57, New Compton-street, London. Amongst the advantages claimed for this type of lamp is that it is "The shortest in the market, will strike an arc on a lower voltage than any other lamp, and makes less noise." The lamp is only 25in. in length including the outer globe. The list illustrates a number of designs, both plain and ornamental.

B.T.H. Plant.—Pamphlet No. 74 issued by the British Thomson-Houston Co., deals with small direct-current motors, type C.A., examples being shown driving sewing machines, ice-cream freezers, &c.

"General" Electric Plant.—Leaflet No. 28 issued by the General Electric Co. illustrates and describes, amongst other matters, overhead trolley line material, suspensions, &c.

Worthington Pumping Plant.—A well-illustrated souvenir of Worthington pumping plant and apparatus is sent out by the Worthington Pumping Engine Co., 153, Queen Victoria-street, London, E.C., illustrating the company's exhibit at Paris and a number of machines erected in various parts of the world. The souvenir can be obtained on application.

"Petroleum."—We have received a copy (No. 3, Vol. I.) of *Petroleum*, the representative organ of the petroleum and allied trades. The new journal has everything to recommend it to those interested in what is already a large industry and promises to become a still larger one. *Petroleum* looks as though it had come to stay. The annual subscription is 10s, single copies 6d.

Argentina Electrical Imports.—The *Review of the River Plate* gives the following figures relating to the imports of electrical goods and appliances into Argentina for the first half of the current year:—

Galvanised iron wire (10,463 tons)	$753,616 gold.
Dynamos (434)	57,231
General material (2,784 cases)	125,687
Cables and wires (629 tons)	277,984
Fittings, including gas fittings (48 tons)	70,280
Electric bells (3,570)	1,785
Porcelain insulators (85 tons)	10,679
Glass insulators (7 tons)	401
Arc lamps, carbon (60 tons)	9,012
Incandescent lamps (18,613 dozen)	53,025
Telephone material (364 cases)	18,672
Telegraph do. (187 do.)	11,884

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Sept. 5 to Sept. 11, with the ports of destination:—

Africa—Alexandria, £170; Cape Town, £179; Durban, £966; East London, £67 (including £44 telegraph material). *Argentina*—Buenos Ayres, £367. *Australasia*—Adelaide, £75; Auckland, £75; Brisbane, £20; Launceston, £35; Lyttleton, £158; Melbourne, £1,142; Perth, £785; Sydney, £1,155; Wellington, £4,256 (including £4,180 telegraph material). *Belgium*—Ostend, £340. *Burma*—Rangoon, £12. *Ceylon*—Colombo, £44. *China*—Shanghai, £184. *Germany*—Emden, £308 (telegraph apparatus); Essen, £60 (telegraph material); Hamburg, £200 (telegraph material). *Holland*—Amsterdam, £70; Flushing, £28. *India*—Bombay, £98; Calcutta, £220. *Malta*—£32. *Portugal*—Lisbon, £105 (telegraph material). *Siam*—Bangkok, £149. *Straits Settlements*—Singapore, £277. Total £12,523, against £5,878 in the corresponding week last year (Sept. 6 to Sept. 12).

PATENT RECORD.

The following list of Applications for Patents and Specifications published has been compiled for this journal by Messrs. J. C. Chapman and Co., *Chartered Patent Agents, of 70, Chancery-lane, W.C., from whom any available information in connection with Patents, Designs, and Trade Marks may be obtained.*

APPLICATIONS FOR PATENTS.

Note.—*The undermentioned Applications are not open to public inspection until after the acceptance of the complete Specification. The names within parentheses are those of communicators of inventions. When complete specification accompanies application, an asterisk is affixed.*

July 4, 1900.

12,054. P. H. Frost-Smith. London. The electric lighting of motor-driven vehicles.

12,074. Siemens Bros. & Co. (Ltd.). London. An improvement in static voltmeters. (Siemens and Halske Aktien Gesellschaft, Germany.)

12,086. A. W. Baxter and C. Baxter. Sussex. Improvements in electrical storage or secondary batteries.

12,089. C. E. Grove. Middlesex. Improvements in dynamo electric machinery.

12,100. E. B. Viles. London. Improvements in or relating to electrical tramways and the like.

12,111. J. Szczepanik and L. Kleinberg. London. Improvements in electrical Jacquards and dobbies.*

July 5, 1900.

12,128. G. S. Holmes. Liverpool. A device for shielding fallen wires from overhead electrical conductors.

12,139. J. Collis and T. J. Kelly. London. "Backing up machine" for mechanically backing up "electro" and "half tone work" either for books, periodicals, or trade work.*

12,152. C. Heim. London. Improved method for the practical application of lead secondary batteries.

12,160. V. Thomas. London. Improvements in the manufacture of filaments for electric incandescence lamps.

12,170. P. Mandowsky. London. Electric meter.*

12,175. The Thomson-Davis Telephone System (Ltd.) and A. T. M. Thomson. London. Improvements in electrical relays.

12,177. W. Walker, jun. London. Improvements in the holders of electrical, incandescent, or glow lamps.

12,179. H. Hirst. London. Improvements in or connected with electrical tramways or railways.

July 6, 1900.

12,249. H. H. Lake. London. Improvements relating to thermo-electric cells. (L. S. Langville, United States.)*

12,256. C. A. M. Bärner. London. Improvements in and relating to electric arc lamps.*

12,267. V. de Robinsky. London. Improvements in electric accumulators.

July 7, 1900.

12,276. Cope, Allman & Co. (Ltd.) and W. Allman. Birmingham. Improvements in hooks or clips for gas and water pipes, electric wire conduits, picture rods and the like.

12,296. B. Russell. London. Improved turbine fan or air propeller, driven electrically or by mechanical power.

12,315. G. Blanck, J. W. Hudson, and W. J. Downs. London. Improvements relating to electrical signalling and communicating apparatus.

12,321. F. Kaeferle. Liverpool. An improved collector for electrical machines and the like.*

12,331. E. Schellbach. London. Improvements in blocks for electric conduits.

July 9, 1900.

12,388. A. J. Boult. London. Improvements in or relating to mechanical motive devices for the controlling drums or switches of electrically propelled vehicles. (E. R. Gill, United States.)

12,391. G. P. Harding. London. Improvements in electric traction.

12,392. Callender's Cable and Construction Co. (Ltd.) and J. C. A. Ward. London. Improvements in clamps for holding the ends of electric fuses or links acting as electrical conductors.

12,393. A. Groves. London. An improved case or cover for electric bell pushes and the like.

July 10, 1900.

12,401. N. E. G. Little. Bolton. Safety fender or life guard to attach to electric cars or other mechanically propelled vehicles.

Digitized by Google

12,434. H. H. LAKE. London. Improvements relating to the manufacture of conducting material for electrical and other purposes. (W. J. Burke, H. A. Kaufhold and T. Russell, United States.)*
12,436. H. H. LAKE. London. Improvements relating to fire alarm apparatus or signals. (J. D. Gould, United States.)*
12,466. G. G. M. HARDINGHAM. London. Improvements in the construction of rail-bonds for electric railways, and in the mode of applying the same. (Felten and Guilleaume Carlswerk, Actien-Gesellschaft, Germany.)

July 11, 1900.

12,469. S. COWPER-COLES. London. Improvements in vessels for containing fused salts during electrolysis.
12,485. R. KRAYN. Manchester. Improvements in chromoscopes.*
12,495. V. I. FEENY. London. Improvements in and relating to frit apparatus. (Allgemeine Elektricitäts Gesellschaft, Germany.)*
12,499. F. VON MADALER, S. BASEL, S. ROSNER, and W. A. GROS. London. Improvements in phonographs.
12,531. C. VON SEDNEFF. London. Positive electrode for accumulators.
12,532. C. VON SEDNEFF. London. Improvements in switches for accumulator electrodes.
12,537. P. F. RIBBE. London. Improvements in and relating to accumulator plates.*

July 12, 1900.

12,554. W. SUNTER. Edinburgh. Appliance for generating electricity to be utilised for propelling machinery and for other useful purposes.
12,591. C. C. T. SOHRMANN and C. M. O. FEIST. London. Improved device for setting fuses or cutouts in electric circuits.
12,598. C. CONTAL. London. Improvements relating to driving axles for electric and other vehicles. (Date applied for under Patents, &c., Act, 1883, sec. 103, Jan. 6, 1900, being date of application in France.)
12,603. ENTWISLE AND STEPHENS (LTD.) and H. J. STEPHENS. London. Improvements in or relating to shades for incandescent electric lamps.
12,609. W. B. BURNIE. London. Improvements in testing sets for measuring insulation resistances.

July 13, 1900.

12,624. E. M. PARSONS. Hull. The Parsons automatic storage battery switch.
12,672. A. VOELKER. London. Improved manufacture of glass by electrical heating, and apparatus therefor.*
12,673. A. VOELKER. London. An improvement in the manufacture of glass by electrical heating.*
12,709. F. M. LEWIS. London. Improvements in electric arc lamps.

July 14, 1900.

12,716. W. B. DALE. Keighley. Improvements in electric switches.
12,733. M. I. PUPIN. London. Art of producing attenuation of electrical waves and apparatus therefor. (Date applied for under Patents, &c., Act 1883, sec. 103, Dec. 14, 1899, being date of application in United States.)*
12,735. H. J. EVERATT. London. Improved electrical railway fog and danger signal apparatus.
12,737. H. OPPENHEIMER. London. Improvements in and connected with keys or switches in lampholders. (Actiengesellschaft Mix and Genest, Germany.)
12,739. J. F. P. RINGSDORFF. London. An improved dynamo brush.
12,743. H. BEHRENDT. London. An improved method of and apparatus for the local application of electrical treatment to the human body.

July 16, 1900.

12,772. J. T. PEARSON. Burnley. Improvements in and relating to arms and trolley for overhead electrically-driven tramcars.

July 17, 1900.

12,837. E. E. BARTLETT and J. E. ROBINSON. Liverpool. Improvements in electrical switches.
12,838. J. W. FERRIER. London. A "safety" carbon holder and carbon economiser for use in electric arc lamps.
12,843. H. E. FRIESE. London. Electric bell.
12,846. J. GLASMACHERS and C. MÜLLER. Germany. Improvements in portable electrical safety lamps.*
12,855. C. JUNGE. London. Improvements relating to the manufacture of bulbs for electric incandescent lamps. (The Oberlausitzer Glashüttenwerke Otto Hirsch, Germany.)
12,874. G. BLANCK. London. Improvements in and relating to telephonic apparatus.
12,876. E. G. JOHNSON, F. D. PALMER, and C. COENEN. London. An improved trolley for overhead electric traction.*
12,893. T. ROSATI. London. Underground wires for transmitting electric energy.*

July 18, 1900.

12,922. Sir W. H. PREECE, K.C.B., and P. CARDEW. London. Improvements in electrical tramways and trains.
12,944. H. F. CLAYTON, T. BELL, and S. S. BERRY. Manchester. An improved electrical switch.
12,950. P. GARUTI and R. POMPILI. Birmingham. Improvements in voltameters for the electrolysis of the water system Garuti.*
12,971. D. R. BRUCE. London. Improvements in electric switches.*
12,973. SIEMENS BROS. & CO. (LTD.). London. An indicator for high electrical tensions. (Siemens and Halske Aktiengesellschaft, Germany.)
12,977. P. E. FRANCKEN. London. Improved electric battery.
12,992. W. J. DAVY. London. Improvements in or connected with electric traction.

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1899.

16,198. OPPENHEIMER (Actien Gesellschaft Mix and Genest). Multiple switchboards.
16,200. OPPENHEIMER. (Actien Gesellschaft Mix and Genest). Holders for electric incandescent lamps.
16,225. NICHOLS and W. T. HENLEY'S TELEGRAPH WORKS CO. (LTD.). Conduits for laying electrical cables.
16,295. PEARMAIN. Plugs for telephone switchboards.
16,300. GOSLIN. Safety fuses for electric circuits.
16,311. SAVAGE and W. T. HENLEY'S TELEGRAPH WORKS CO. (LTD.). Dry core electrical cables.
16,410. ECKSTEIN and ANGOLD. Electric arc lamps.
16,600. NISBETT. Manufacture of earthenware troughs for carrying electric cables and analogous purposes.
16,628. ANDREWS. Arc lamps.
16,820. MILLS (David and David). Electrically controlled design reading apparatus for punching jacquard and like cards.
16,956. BATE. Conduits for electric conductors.
17,262. WINTER and FÜTTER. Arrangements of connections and conductors for railways worked by electricity.
17,410. HADDAN (Goldstein). Electric accumulators.
17,719. LORRAIN. (Macdonald). Variable-rate electric meters.
18,040. CUTMORE. Telephone speaking tube and like receivers.
18,064. LITTLE and IRELAND. Electric trolley standards.
18,200. KENNEDY. Ships' telegraphs.
18,335. BREMER. Electrodes for arc lamps.

1900.

559. WISE (Aktiengesellschaft Elektricitäts-werke vorm. O. L. Kummer & Co.) Transformers.
956. WILSON. Telephone apparatus and induction coils for use therewith.
2,703. SCHLOMANN and DE CASTRO. Process and apparatus for electrolytically treating ropes, hose, cork, asbestos, and textile fabrics of all kinds.
3,174. MENGIS. Long distance telephony.
3,203. LECARME and LECARME. Interrupters for electric circuits.
5,088. THOMSON (Brown). Bonding for iron or steel electrical conductors.
8,465. BOULT (Collins). Electric motors.
8,486. EDISON. Apparatus for duplicating phonograph records.
9,458. EGLIN. Space telegraphy.
9,730. WORSLEY and GREEN. Electric switches.
10,137. KRAYN. Electric lamps.

NEW COMPANIES, STATUTORY RETURNS, &c.

ELECTRIC INCANDESCENT LAMP REGENERATING SYNDICATE (LTD.) This company was registered on Sept. 8, with a capital of £7,500, in £1 shares, to acquire certain patents and to carry on the business of electrical and general engineers, electricians, contractors, &c.

LIQUID AIR POWER AND AUTOMOBILE CO. OF GREAT BRITAIN (LTD.) This company was registered on Sept. 5, with a capital of £200,000 in £1 shares, to enter into an agreement with Mr. T. J. T. Huteson and to carry on the business of producers of and dealers in liquid air, manufacturers of apparatus for use in connection with its production, storage and utilisation of liquid air, cycle, motor car and carriage builders, &c., and electrical, mechanical and general engineers, &c.

SHERARD COWPER-COLES & CO. (LTD.) — This company was registered on Sept. 4, with a capital of £25,000 in £1 shares, to acquire the business now carried on by Mr. Sherard Cowper-Coles, and to carry on business as electricians, electrical and consulting engineers, metallurgists, suppliers of electricity, chemists, chemical manufacturers, machinists, &c. The subscribers are: H. R. Braid, electrical engineer; E. G. Woodridge; H. Sayer, metallurgical chemist; H. Groome, electrical engineer; M. A. Hankey, electro-metallurgist; F. S. Spiers, electro-chemist; and C. E. Peczenik, engineer. The first directors are: The Marquis of Queensbury (chairman), Messrs. W. B. Cowper-Coles (deputy-chairman), J. Day, R. Steele and S. H. Cowper-Coles.

BRITISH ELECTRIC TRANSFORMER MANUFACTURING CO. (LTD.)—The annual return to Aug. 17 has been filed. The capital is £500,000, in 200,000 vendors' and 30,000 ordinary shares of £1 each, of which 20,000 vendors' and 20,000 ordinary have been taken up. £1 per share has been called up and paid on the ordinary shares. The 20,000 vendors' shares are considered as fully paid.

CHILI TELEPHONE CO. (LTD.)—The annual return to Aug. 24 gives the capital as £250,000, in £5 shares, 44,000 of which have been taken up and paid for in full.

COLUMN PRINTING TELEGRAPH CO. (LTD.)—According to the annual return to Aug. 13 the capital is £25,000, in £50 shares, 289 of which have been taken up. £50 has been called up on 189 shares, and £8,940 has been received, leaving £510 in arrears. £5,000 is considered as paid on 100 shares.

MARCONI INTERNATIONAL MARINE COMMUNICATION CO. (LTD.)—The annual return to Aug. 15 gives the capital as £350,000, in £1 shares, 204,000 of which have been taken up. 5s. has been called up on each of 99,000 shares, and £24,349 has been received. The remaining 105,000 shares are considered as fully paid.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since July 19, 1900). Price of silver 28⅛d. per oz. (Sept. 13). Consols (2¾ per cent.) 98½—98⅝ for money, 98⅝—98¾ for account; 2½ per cent. 97½—97¾ (Sept. 13). Stocks and Shares Continuation Days, Sept. 26 and Oct. 10; Ticket Day, Sept. 27; Pay Days, Sept. 14 and 28; Mining Share Carry-over Days, Sept. 25 and Oct. 9.

BRITISH ELECTRIC WORKS CO. (LTD.).—The directors' report for the past 16½ months has been issued, and states that, after payment of debenture interest, there was a loss of £12,803 on working.

COMPAGNIE D'ELECTRICITE THOMSON-HOUSTON DE LA MEDITERRANEE.—The capital of this company, whose area of operations includes Greece, Italy, Spain and Portugal, has been increased from 10,000,000fr. to 20,000,000fr. (from about £400,000 to £800,000.)

DIRECT SPANISH TELEGRAPH CO. (LTD.)—The board have decided to pay, in addition to the dividend at the rate of 10 per cent. per annum on the preference shares, an interim dividend at the rate of 4 per cent., tax free, on the ordinary shares, both for the half-year ended June 30, 1900, and payable on Oct. 1, next.

ELECTRICAL PROGRESS IN RUSSIA.—An extraordinary meeting of the Russische Elektricitäts Aktien-gesellschaft Union of St. Petersburg will be held on 25th prox. to consider a proposal to issue a loan for increasing the working capital, and also to purchase a site for electricity supply works at Kiew, and to form a company for erecting and operating the works.

W. T. GLOVER & CO. (LTD.)—The preference share transfer books will be closed from 17th inst. to 29th inst. inclusive.

W. T. HENLEY'S TELEGRAPH WORKS CO. (LTD.)—In the recent issue of ordinary and preference shares both classes were, we are informed, largely over-subscribed.

WESTERN UNION TELEGRAPH CO. (LTD.)—The executive committee recommend the payment of the usual quarterly dividend of 1¼ per cent. The statement for the quarter ending Sept. 30 (partly estimated) shows: Net earnings, $1,600,000 (decrease $77,000); balance after charges, $1,361,000 (decrease, $81,000); surplus after dividend, $144,000 (decrease, $81,000); total book surplus, $8,602,000.

NOTES.

THAT the city of Manchester has been suddenly isolated telegraphically from the rest of the world is a most startling event, occurring as it does when the summer is hardly spent, and the climatic conditions are all that could be desired. We are accustomed to such breakdowns in the winter time, and are ready to accord the praise it deserves to a department which so speedily repairs all damages. But this disaster, originating at a single point, so far-reaching in its consequences, and yet so trivial in its origin, is likely to create surprise of a very disagreeable kind. It would appear that the whole telegraph service, and to some extent the telephone service, centred in the Manchester office is liable to utter destruction by the misuse or careless handling of a spirit lamp in the rear of the test-box. The lamp seems to have burst, as these lamps are apt to do; and the result in this case was to set the inflammable coverings of the wires and the dry woodwork adjoining ablaze. The conflagration, thus merrily started, soon spread to the roof, which duly fell in, destroying all the telegraph instruments beneath and wrecking the poles and standards on the top. Many days will elapse before temporary arrangements can be made to re-establish communications in fresh premises, and meanwhile the most important commercial city in England, next to London, is deprived of its customary means of intercourse with the business world.

JUDGMENT may be suspended until more detailed particulars of the accident come to hand; but on the face of it we are entitled to say that it ought never to have occurred. Whatever the form of spirit lamp employed it had no business to be in such a critical position; and if, as is most probable, the lamp was a "roarer" its employment would be little less than criminal. Further details of the conflagration are given in another note. To add to the confusion of Cottonopolis, the electric light broke down at eight o'clock the same evening. Owing to the interruption of telephonic communication we are unable to ascertain exactly what occurred; but it appears that the breakdown was complete while it lasted, the street lighting, and the lamps in theatres, private houses, &c., being extinguished throughout the city.

THE resolutions of the Cable Makers' Association with regard to specifications of electric supply mains were published on p. 790 of our last issue, but arrived too late to enable us to comment on them then. We have frequently emphasised the importance both to cable manufacturers and cable users of establishing certain conventions as to the sectional area and resistance of electric light cables; for up to the present, owing to the uncertain effect of the "loss in lay" on the resistance of a stranded cable and the practice of specifying the size of cable in terms of the "equivalent sectional area," the same specification could easily convey to different engineers and manufacturers different ideas as to the size and weight of the conductor. The table forming part of the cable makers' manifesto gives the number and size of wires to be employed for each sectional area and the resistance that the cable should have in each case—although the latter information is valueless as it stands, owing to the omission to state at what temperature the conductor is to have this resistance. Apparently the values are calculated for 60°F.

WITH regard to the constant cry of manufacturers for standardisation, we have always pointed out that the remedy lay in the hands of the manufacturers themselves. If each manufacturer standardised his own wares it would be a great advance, and the next step would evidently be an agreement among leading manufacturers to adopt the same standards. In cables for electric light and power supply we have reached this point therefore, for the Association who have signed this report include all the leading English manufacturers of cable of this class. Unanimity as to the terms of contracts is also a great benefit to the industry, especially the resolution as to the non-finality of the engineer's decision. This conversion of an arbitrary clause into an

Digitized by Google

arbitration clause should also be insisted upon in the case of tenders for other material than cable.

We print in another column an interesting and instructive communication from Mr. H. G. Barwell, under the heading of "A Common Phenomenon noticed in Cable Work," which we think throws some light upon a subject at one time undoubtedly regarded as somewhat of a mystery by those engaged in submarine cable laying and repairing. It was frequently noticed when a splice between two types of cable was paid out into the sea that peculiar sharp kicks were observable upon the galvanometer employed for keeping a constant test upon the cable during the operation; and these kicks were sometimes so marked that they have not infrequently given rise to the suspicion that an incipient fault had developed in the cable, with the result that paying out has been temporarily suspended until further tests could be taken

In recent years, however, the true cause of the phenomenon has been realised by more than one cable engineer, and Mr. Barwell's observations and experiments tend to confirm their ideas upon the subject. As a proof of this, it is the usual practice now, when making a splice on board ship between two types of cable, to remove all taping from the outer sheathing wires and to scrape and clean them thoroughly at intervals; and good contact between them is further ensured by binding the parts so cleaned together with iron-wire wrappings. If this is effectually and carefully done, the phenomenon under notice is usually conspicuous by its absence. Mr. Barwell's Paper is of interest, however, in that his experiments tend to confirm the accuracy of previous surmises, and the method he suggests of "listening" for the approach of a fault or splice when picking up might very well, under certain conditions and in some circumstances, be extremely useful.

The Paper on "Electrolysis of Underground Metal Structures," which we reprint this week, has the recommendation of being written from the point of view of the complainant owners of such structures. The author, Mr. D. H. Maury, is the engineer to a large waterworks at Peoria, in the State of Illinois, and for many years he has evidently being taking careful stock of the mischief wrought by stray currents from electric tramways. He brings now a serious indictment against the overhead trolley system, and backs up his charges by a formidable array of actual instances, many of which are exhibited in photographs which we have reproduced. The subject is of pressing importance, and electrical engineers are as ready as anyone to admit it. None are more eager for a real solution of the difficulty which shall completely and permanently remove the mischievous tendency to corrosion. It is a libel on their profession to hint that their motive in recommending the bonding of water pipes to the negative conductor is merely to obtain a better conductivity for their return current, and thus to reduce their coal bills. The charge is preposterous. Traction engineers are seriously in earnest in their desire to prevent corrosion; for they know well enough that the popularity of the trolley system is menaced if damage is continually being done to water mains and similar underground conduits. It is an incidental effect that the public—the British public, at any rate—would not long stand.

They appear to be less exacting in America, notwithstanding that the traction companies are palpably more careless. Fortunately, as we have often said before, we in this country have a Board of Trade. Its regulations in regard to tramway leakage may not be all that could be desired; but they are, at any rate, restrictive. Illogical from the beginning, and now gradually being shown by practice to be ineffective, the 7-volts limit is a measure of protection that greatly postpones, though it fails to mitigate, the final catastrophe at the water mains. Seven limited volts are preferable to 70 unlimited—common enough in America! Nevertheless, postponement is not a real solution of the problem. Terrible as it may be to contemplate that American practice precipitates the aqueous irruption in five or six years at most, British practice gains little or no security from the fact that the calamity approaches at no more than one-fourth the pace. There must be no damage at all.

We do not admire Mr. Maury's proposed solution of the difficulty. Having carefully examined on the spot "the double trolley system, overhead, as at Cincinnati," we relegated it to the limbo of curious failures. There are many people of Cincinnati who would gladly do the same with its outward and visible manifestation in that city. Better far than this aerial nightmare to provide the ordinary trolley with an underground insulated return connected permanently to a series of surface contact-studs on the track. We do not think this has ever been tried. The principal drawback to the surface-stud systems in their entirety is the complicated mechanism necessary for rendering the studs alive only when a car is over them. The difficulty vanishes when all the studs are on the return conductor and are never at more than, say, 7 volts above earth potential. This would be but little more costly than the ordinary trolley system, especially when it is remembered that much paraphernalia in the shape of rail bonding, negative boosters, &c., would be rendered unnecessary. Moreover, it is a modification that any trolley traction company or authority, with proclivities in underground corrosion, can be made to adopt at any time without involving serious change in the electrical system of working.

A letter from Prof. J. Chunder Bose this week illustrates in a striking manner how theoretical research may assist practice with useful suggestions. While mainly engaged in trying to evolve a satisfactory theory of the coherer, Prof. Bose has observed phenomena which indicate what may be the best course to follow in wireless telegraphy. Thus, it having been ascertained that with many materials a strong electric radiation produces the opposite effect to that excited by weak radiation, it follows, Prof. Bose shows, that in wireless telegraphy the point-coherer should prove the most sensitive arrangement. The steps in the argument leading to this conclusion are clearly laid down in Prof. Bose's letter. We trust that, in the leisure from his actual researches, he will bestow on his practical brethren some further suggestions of

Digitized by Google

this kind; for it is undoubtedly those who best can interpret sound theory who are most competent to lead practice.

THOUGH there is truth in the saying that all the sciences are "but parts of one stupendous whole," M. WILLOT's recent attempt to establish a practical link between stratigraphical geology and wireless telegraphy scarcely illustrates the truism. Acquaintance with the bowels of the earth may be useful knowledge to an electrician, but who would have supposed it would lead to his sending wireless messages along various courses by confining them each to its own allotted geological stratum? Yet such is the proposal made by M. WILLOT, an Inspector of French Telegraphs, at the International Congress of Electricity, at Paris. According to a daily contemporary, the French Telegraphs Department is so enamoured of the scheme that it has appointed a committee "to sink electric pits in different places in order to find out the distribution of electric levels under the earth." Electric pitfalls!

Erratum.—In our report last week of the discussion on "Ions" at the British Association, p. 783, line 26, for "five electrons" read "free electrons."

East London Technical College.—Some particulars of the courses in physics, engineering, mathematics and chemistry are given in an advertisement. Calenders can be obtained from the Director of Studies (Mr. J. L. S. Hatton).

City of London College.—The Michaelmas terms of this college commence October 1. Classes are held on magnetism and electricity, sound, heat, light, mathematics, chemistry, and other science subjects. Prospectuses can be obtained of the secretary, Mr. David Savage, White-street, Moorfields, E.C.

Cable Interruptions and Repairs:—

	Date of Interruption.	Date of Repair.
Latakia—Cyprus	June 21, 1899 ...	—
Cayenne—Pinhieros	Oct. 11, 1899 ...	Sept. 17, 1900

Finsbury Technical College.—At the Technical College, Finsbury, the evening courses begin on Monday, October 1st. Prof. Silvanus P. Thompson opens the Monday evening (Advanced) course with an introductory lecture on the Distribution of Electricity, the succeeding Monday evenings until Christmas being devoted principally to the subject of the Design of Continuous-Current Dynamos and Motors. On Wednesday evenings Dr. E. W. Marchant will lecture on Electric Currents and Methods of Measurement. Prof. Thompson will also give a short course of Special Lectures on Fridays on the Polarisation of Light.

Chinese Cables.—The Eastern Extension and Great Northern Telegraph Companies announce that the laying of the submarine cable between Shanghai and Chefoo has been successfully completed and the line opened for traffic. This, with the Chefoo-Taku cable recently laid by the companies, provides submarine telegraphic communication to Chefoo and Taku, available for international traffic, entirely independent of the Chinese landlines and without any addition to the existing tariffs. The companies also announce the laying and opening of branch cables between Chefoo and Wei-hai-Wei and between Chefoo and Port Arthur.

Appointments.—Mr. L. R. Wilberforce, M.A., demonstrator in physics at the Cavendish Laboratory, Cambridge, and University Lecturer in Physics, has been appointed to the Lyon Jones Chair of Experimental Physics at University College, Liverpool, vacated by the appointment of Dr. Oliver Lodge to the Principalship of the University of Birmingham.

The Admiralty has created an important new post in the dockyard staff, namely that of electrical engineer, to rank next to the four chief assistant engineers. To fill this post the Admiralty has chosen Mr. Louis J. Steele, M.I.E.E., late chief engineer to Messrs. Verity, and formerly assistant engineer with Messrs. Johnson and Phillips. Mr. Steele received his training at the Technical College, Finsbury, under Prof. Silvanus Thompson and Prof. Perry, and was awarded the certificate of the College in 1890. He will be attached to the dockyard staff at Portsmouth.

Obituary.—We regret to record the death of Mr. Abdank-Abakanowicz, a prominent engineer on the other side of the Channel. Bruno Abdank-Abakanowicz was born in Wilkomir, Poland, in 1852. After graduating at the Riga Polytechnicum he occupied the chair of Graphical Statics and Applied Mechanics at the Lemberg Polytechnic from 1874 to 1881, after which he went to Paris and established himself there as a consulting engineer. He has published books on graphical statics and integrating machines, and also many Papers in the *Comptes Rendus* of the Academy of Sciences and various other French publications. Mr. Abdank-Abakanowicz was a Knight of the Legion of Honour, member of the Société de Physique, and member of the Council of the Société Internationale des Electriciens. He was also one of the founders of our esteemed contemporary *L'Industrie Electrique*. In 1889 he organised the United States Section of the Paris Exhibition, and was nominated member of the jury, and he was intimately connected with the French Thomson-Houston Company and other leading firms.

The Propagation of Electric Waves along Parallel Wires.—In a communication on this subject to Section A of the British Association, at Bradford, Mr. W. B. Morton states that in the *Annalen der Physik* for June, 1900, a very complete investigation of this problem has been published by G. Mie. He finds expressions for the wave-length and damping of the oscillations involving a series of ascending powers of the ratio of radius of wires to distance apart. The object of this communication is to point out that the approximate solution, in which the square of this ratio is neglected, can be very easily obtained from the known solution for a single wire, as worked out by Prof. J. J. Thomson and by Sommerfeld. The formula for the damping agrees with that given by Heaviside's simple theory when Lord Rayleigh's high-frequency values are used for the resistance and inductance. Attention is called to an error in the formula for the K_0 function in the work of Thomson, Sommerfeld, and Mie, arising probably from an erratum in Heine's "Kugelfunctionen"; it affects the numerical values worked out in Sommerfeld and Mie's Papers.

The Third-rail System in the United States.—During the last few weeks there has been an outcry against the use of the third-rail system on the elevated railways in Brooklyn. Here, as in other towns in the United States, the third-rail is employed extensively, but recently there have been several accidents to workmen in which shocks from the unprotected line rail were a contributory cause. The Deputy Commissioner of the Department of Public Buildings Lighting and Supplies has in consequence issued an order to the railway companies that they must either make the system absolutely safe or do away with it entirely; and a New York contemporary states that the authorities have ordered that on Brooklyn bridge the charged third-rail must either be removed or protected by guards 3in. high on either side of it. The Baltimore and Ohio Railroad Co. on its new third-rail system through the Belt Line tunnel has encased the third-rail between two planks set on edge, and it is possible that similar expedients may be adopted on other lines. There should be no great difficulty in either placing the third-rail in a safe position or protecting it sufficiently to prevent accidents.

An 1887 Electric Railway.—A description of an electric tramway built in Wichita (Kansas) as long ago as 1887, is published in the September number of the *Street Railway Journal*. Mr. T. C. Hughes, the writer of the article in our contemporary, obtained the concession and was responsible for the erection of the line. The track was of 40lb. girder rail. In the power house were two 100 H.P. horizontal tubular boilers, a horizontal high-speed engine, and a Brush dynamo with an output of 60 amperes at 1,000 volts. The trolley wire was a hollow copper tube ¼in. diameter and

Digitized by Google

about $\frac{1}{32}$in. thick, made in 18ft. lengths. At the end of each length was a switch, whose function was to cut out of circuit the section of the trolley wire immediately above the car. Two trolleys pulled by a flexible cord were attached to the roof of the car with spring clamps, one at either end of the car, at a distance apart about 4ft. greater than the length of the sections of the overhead conductor. The front trolley opened the switch as it passed, and the rear trolley closed it, so that the motor was always cut in in series with the line. Thus the return wire could be a separate pole line, independent of the car. The trolley wire and switches were suspended every 5ft. by insulating supports from longitudinal cables, carried by, but also insulated from, span wires, which were stretched between wooden poles. The trolley itself consisted of a frame carrying five wheels, and, as will be readily understood, its construction and that of the section insulator and switch was fairly complicated. The motors were mounted in a rigid frame, journaled at four points on the axles, and geared to one axle with coil wire belts. As might be expected, the line was only kept running a short time; and, moreover, a proposition to remodel the line on the parallel instead of the series system and to mount the motors on a spring suspension was rejected.

An Experiment on Simultaneous Contrast.—At a meeting of Section A of the British Association at Bradford, Mr. G. J. Burch described an experiment on this subject. It is well known that white objects seen against a red background look greenish-blue, and orange against a blue background. This phenomenon is shown in a striking manner in the following experiment due to Hering: A small white disc is viewed with the left eye against a red background, and another similar disc is viewed against a blue background with the right eye. The discs are so placed as to occupy different positions in the field of view. The result, when the light has been properly adjusted, is that the observer sees an amethyst-blue disc and a topaz-yellow disc against a pale purple ground. The reason of this is demonstrated by the author in the following experiment: Two pieces of glass, one red and the other blue, are inserted in a stereoscope in place of the usual slide, each glass having two small squares of black paper on it. Viewed binocularly the four squares appear as two. In front of the instrument, but out of the direct line of sight, are two adjustable slits, and over the eye-lenses of the stereoscope are two diffraction gratings. The position of the slits is so arranged that the spectrum of the first order of the left-hand grating falls on the right-hand square, and that of the right-hand grating on the left-hand square, the two spectra, which can be adjusted to the same intensity, being thus seen side by side, one with the left eye on a red ground, and the other with the right eye on a blue ground. The red glass produces partial red blindness of the left eye, and the spectrum seen by it lacks red, the other colours being unaltered. And for a similar reason the spectrum seen by the right eye lacks blue, the effect being more noticeable owing to the contrast of sensation in the two eyes. In the author's opinion this experiment affords further confirmation of the views of Scherffer, Darwin and Young in regard to contrast.

A New American Trolley Head.—The *Street Railway Review* for August contains a description of the Feist trolley head recently brought out in the United States. We extract the following particulars from our contemporary's description: The device consists of a two-piece harp, made of malleable iron, and a hardened steel axle, threaded at its ends, connecting these pieces. Four holes are bored in this axle, in each of which is carried a graphite pencil of special composition, these pencils being held against the bearing of the trolley wheel by helical springs in such a manner as to secure constant and even lubrication and assure positive contact. One set of lubricating pencils outlasts a 20,000-mile wheel. Thin lubricating washers are placed on this axle between the wheel and the arms of the harp, thereby ensuring lubrication here, and preventing cutting such as would occur with a metal washer. The axle for a two-motor equipment is 1in. in diameter, while for a four-motor equipment it is made $1\frac{7}{16}$in. in diameter. The size of these axles offers an increased bearing surface, thus insuring ample contact and a materially longer life to the wheel, both bearing and axle being evenly and thoroughly coated with the lubricant. An even wearing away of the bearing is thus obtained, effectually obviating the objections to be found in some of the present graphite bushing combinations, where the wheel bearing is not sufficiently lubricated, causing it to wear away in parts unevenly, and so rapidly becoming loose, causing destructive arcs between the wheel and its axle. This results in blistering the axle, and hence there are frequent renewals and repairs, to say nothing of the short life obtained.

Serious Fire at the Manchester Postal Telegraph Office.—A fire, attended with serious consequences, occurred on Wednesday afternoon at the Manchester Central Post Office, doing considerable damage to that part of the building occupied by the telegraph department, and causing great destruction of telegraph apparatus and plant. According to the *Standard*, the fire was first discovered in a test-box, behind which were a number of wires. Suddenly flames were seen coming from the box, and immediately the whole apparatus was enveloped in flames. The woodwork in the room being very dry, the fire spread with alarming rapidity. The efforts of the clerks in the room to subdue it made not the least impression, the fire-extinction apparatus on the premises proving wholly inadequate for the emergency. The city fire brigade were telephoned for and arrived in great force. In a short time they gained mastery of the flames, but not before the roof had fallen in and the telegraph instruments were so completely wrecked as to cut off the city from telegraphic communication with the rest of the world. The vast collection of wires erected over the building were of course dislodged from their supports, and a great number of lines were not merely interrupted, but absolutely destroyed. The outbreak occurred about half-past one o'clock, when there were 300 or 400 operators in the room. There was no panic, however, their retirement being effected in perfect order. The fire, it appears, was caused by the bursting of a spirit lamp which was being used by some employés of the engineering department, who were repairing the wire coils near the test-box. This is the point where all the wires entering the building converge, and is, accordingly, one of the most important spots in the building. The department of the Engineer-in-Chief in London was immediately communicated with, and it is hoped that the assistance obtained from there, as well as from the engineering departments of some of the other principal offices in the country, will enable the Manchester authorities to remedy the effects of the disaster in the course of a few days. The Manchester Post Office is one of the busiest outside London, being the chief centre for telegraphic distribution through the North of England. The various wires converge at Manchester and spread, in a great network, north, south, east, and west. Many important towns are served from the building which has been so seriously damaged by Wednesday's outbreak, and thus the difficulty arising from the isolation of the city is shared by business people over a very wide area. The building, which was opened in 1884, is constructed of Portland stone, and cost about £120,000. The total number of employés is 2,200. The telegraph instrument room in which the fire broke out is 400ft. in length and 83ft. wide, and contains 250 instruments. To meet the emergency in regard to telegrams the authorities of both cities promptly utilised the excellent train service between Manchester and Liverpool. Thus telegrams handed in at Manchester for transmission to distant places were trained every half-hour to Liverpool, and there put on the wires; whilst, vice versâ, messages from all parts of the country for Manchester were wired to Liverpool and thence trained to Manchester. In telegraphic matters the Post Office is noted for the promptitude and ingenuity with which it can cope with an interrupted communication, and many thousands of messages have been already thus diverted. A system is being organised by means of which Lancashire and Yorkshire towns, whose "transmitting centre" ordinarily is Manchester, will be connected through to Liverpool, which, until the Manchester office is at work again, will be the transmitting centre. A vast amount of extra work will be thrown on the Liverpool office, but every effort will be put forth to successfully cope with it.

THE NEW ELECTRICITY WORKS OF THE GLASGOW CORPORATION.

(*Continued from page 767.*)

The Port Dundas Station.

Site of Buildings.—A satisfactory feature of the Port Dundas station is its position with regard to the Forth and Clyde canal. The canal is at a considerably higher level than the engine room floor, and the ground falls away rapidly from the canal to the roadway. Although this necessitates the coal store, boiler house, engine room, and accumulator house being on different levels, it offers considerable advantages as regards the supply of fuel.

The station is a handsome pile of buildings of red pressed bricks, relieved with red sandstone facings, designed under Mr. Chamen's direction by Mr. Andrew Myles, an architect who has designed many large engineering works in Scotland. The coal store is capable of containing over 2,000 tons of fuel. The boiler house (see illustration in our last issue, p. 767) is 558ft. long by 81ft. wide. It is arranged for only one line of boilers facing towards the coal store and leaving ample space in the rear for economisers, steam pipes, etc., as it is intended as far as possible to keep all steam pipes in the boiler house. There is no ring main, but arrangements are made so that the main steam pipe can be relieved of all pressure at certain times without shutting down the station.

The plans are made for three chimneys, dividing the space behind the boilers into four lengths. The centre chimney, which is the only one at present built, is 200ft. high and 11ft. in diameter; it is built on a square base which reaches to about the roof level, the shaft being of a circular section with an ornamental cap. It is constructed of red pressed bricks and lined with firebrick. Protection is afforded from lightning by a ring of collecting points attached by several diagonal bands to two copper lightning conductors. The other two chimneys are each 250ft. high and 13ft. diameter.

Next to the boiler room and parallel with it, but again on a lower level, is the engine room, which is about 57ft. in width. It is spanned by a 25-ton travelling electric crane by Messrs. Broadbent & Sons, which should be large enough to deal with sets of plant up to 2,500 H.P. capacity. Next to the wall of the boiler house is a trench along which water tanks on weighing machines can be run for the purpose of measuring the condensed steam from the air pump of any engine which may be under test. As will be seen from the detailed description of the plant, all the larger sets are fitted with separate surface condensers, have the air pumps driven directly by the rocking shaft and connecting rods, or more generally in all the recent plants by independent electric motors. The cooling water is taken from the canal at one end of the engine house and returned to it at the other, the necessary pumps for this purpose being of the centrifugal type electrically driven, but owing to the position of the canal very little power is required to effect this purpose. There is another trench on the opposite side of the engine room along which all the feeders are led.

In front of the engine room, and forming the main frontage of the buildings, is in the centre the main entrance, flanked on either side by a battery room 77ft. long by 26ft. wide. The tower itself contains the station engineer's office, an important feature of which is its bay window, which projects over the engine room, enabling the engineer to look from end to end of the engine house without leaving his room. Another special feature is an overhead gangway, which is reached direct from the engineer's room by a spiral staircase. This gangway passes across the engine room above the level of the traveller, and thence across the boiler house, and out on to the towpath by the canal.

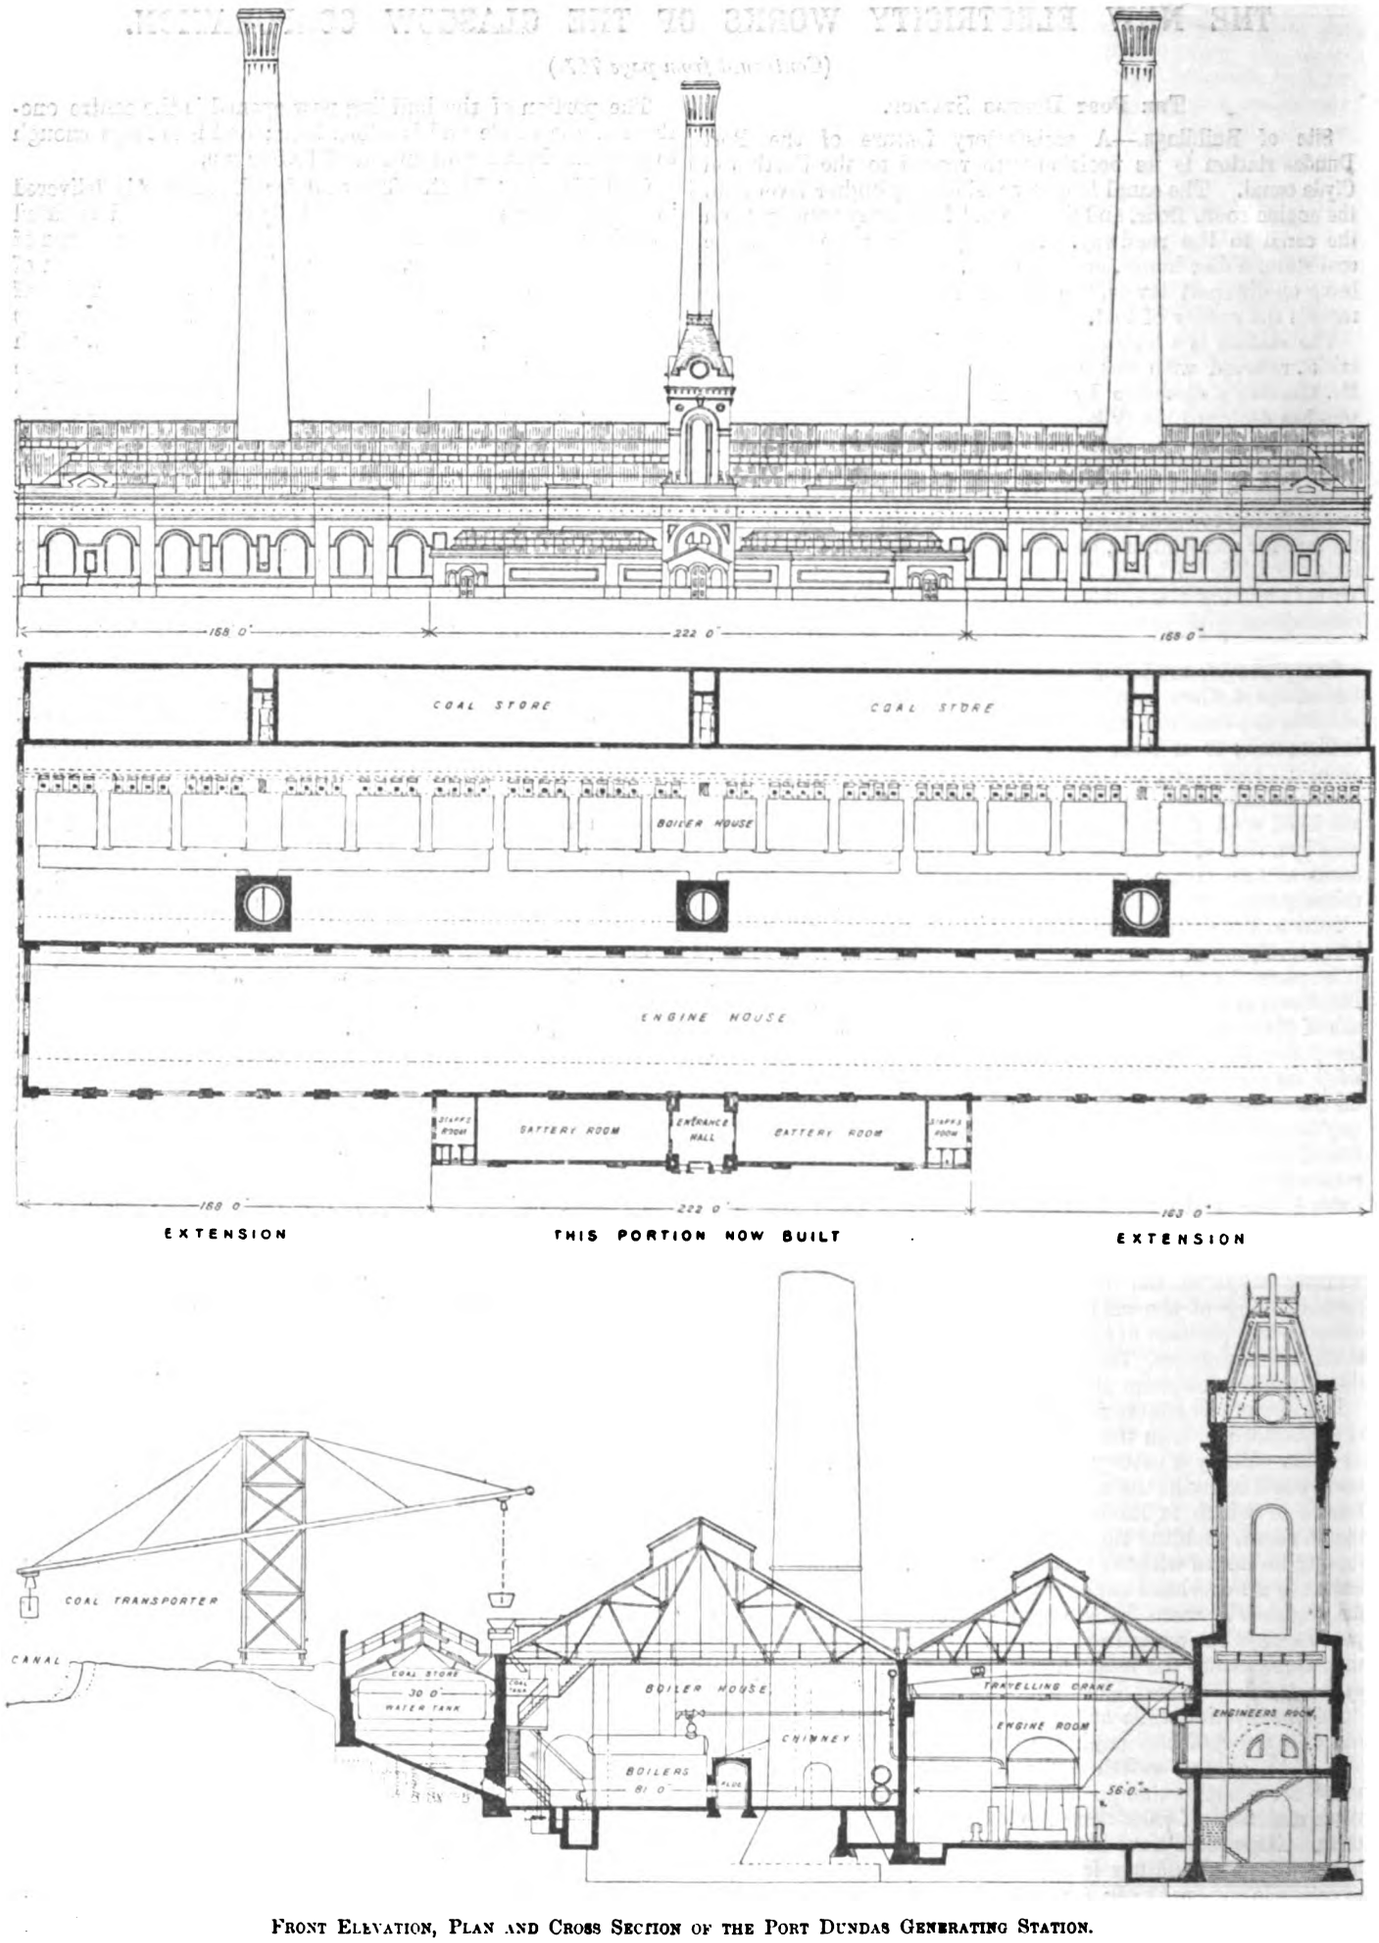
All the interior walls are covered with white glazed bricks, and the floor of the engine room is laid with granolithic. The floor of the switch gallery is laid with glass blocks, which serve the double purpose of giving a good light underneath and also of insulating the switchboard attendant from earth. Glass roofs have been employed throughout. Another feature of the buildings is the ample bathroom and lavatory accommodation, not only for the engineers, but also separate accommodation for the foremen and staff.

The portion of the building now opened is the centre one-third of the whole and is 220ft. long; and it is large enough to contain plant for an output of 10,000 H.P.

Coal Handling Plant.—The coal for the station is delivered in 30-ton barges by the Forth and Clyde Canal, and is lifted out of the barges at the rate of 30 tons an hour by means of a Temperley transporter, handling 1-ton lifts, the boom of which spans from the centre of the barge to the far side of the bunker roof. The transporter is made to travel on rails laid on the wharf; the gauge of the rails is 19ft. 4in., which is much larger than required for the transporter itself, but the conditions were such that no support for the rail could be made for a less gauge. The arm of the transformer which projects over the canal is made to hinge up in a vertical direction in order to clear the rigging of vessels when coming along the side, and to give a clear headway when required over the wharf. The overhang on the water side is 45ft., the overhang on the land side is 41ft., the centres of the tower uprights 12ft., giving a total effective travel of 98ft. The power plant is situated on an extended platform and is covered by a galvanized iron house, with glazed windows to enable the driver to have a clear view of the load during lifting, travelling and lowering. All the motions of the transporter are driven electrically by a 500-volt 20kw. British Thomson-Houston enclosed motor. The gear is capable of lifting 25 cwts. at a speed of 300ft. per minute, and of travelling along the beam at a speed of 600ft. per minute, the driver being able to propel the entire transporter along the rails in either direction by the simple movement of a lever. A load can be taken up or let down at every 5ft. along the beam. There is an automatic arrangement by which, as soon as the fall block enters the hood of the traveller, the weight of the load is taken off the hoisting rope, and the load is suspended directly from the traveller running on the beam. This arrangement unlocks automatically when the load is to be lowered. The complete operation, viz., lifting the full skip from the barge, travelling along the beam, lowering, and the return of the empty skip to the barge, is performed by means of one rope driven from the motor on the power platform, and only one man is required to work the transporter. The coal in the barges is filled into skips, these skips are lifted by the transporter, carried along the beam, and deposited into a travelling weighing machine, of Messrs. Pooley & Sons' make, which records the amount of coal passed through it, and passes it into diverting boxes, each fitted with two shoots, which deliver the coal into a reserve bunker holding 4,000 tons, or into steel coal tanks, holding 60 tons each, one of which is situated opposite to but above the level of each boiler. When the boilers are being fired a trap in the bottom of the tank is opened and the coal runs down an inclined shoot into the hopper of the mechanical stoker at its lower end. These shoots are hinged so that they may be slung back from the reserve bunker, which runs parallel with the whole length of the boiler house, and advantage has been taken of the fact that the building stands on the slope of the canal bank to incline the floor of the coal store to about 45deg., so that no trimming is required.

Boiler-house Plant.—The 10 boilers which are being erected at present are all of the Babcock and Wilcox make, containing 4,020 sq. ft. of heating surface, and each is capable of evaporating 15,000lb. of water per hour working at a pressure of 200lb. to the square inch. They are all fitted with Babcock and Wilcox chain grates and mechanical stokers, which are driven electrically by enclosed motors of the General Electric Co.'s make. The grates, detailed descriptions of which have already appeared in *The Electrician*, are mounted on carriages and may be removed complete from under the boilers for examination or repair. The clinker and ash is shot over the back of the grate into a recess, from which it falls through an opening in the ashpit into the ash tunnel, running under the ashpits for the whole length of the boiler-house. A tramway line fitted with a complete system of wire rope main and tail

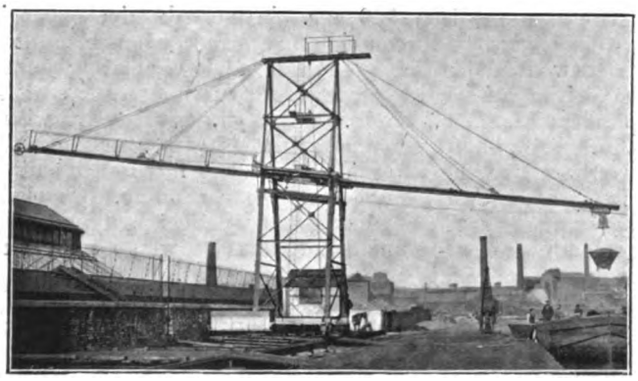
Digitized by Google



FRONT ELEVATION, PLAN AND CROSS SECTION OF THE PORT DUNDAS GENERATING STATION.

Digitized by Google

haulage, electrically driven, removes the ash from the tunnel on to a siding in the yard, where it is deposited in carts for removal. The boilers are fitted with the latest safety devices, Hopkinson water gauges and feed fittings, Babcock and Wilcox high and low-water sentinel valves, duplicate dead-weight safety valves, Babcock and Wilcox superheaters, Schaefer and Budenberg steam valves with steel seats and

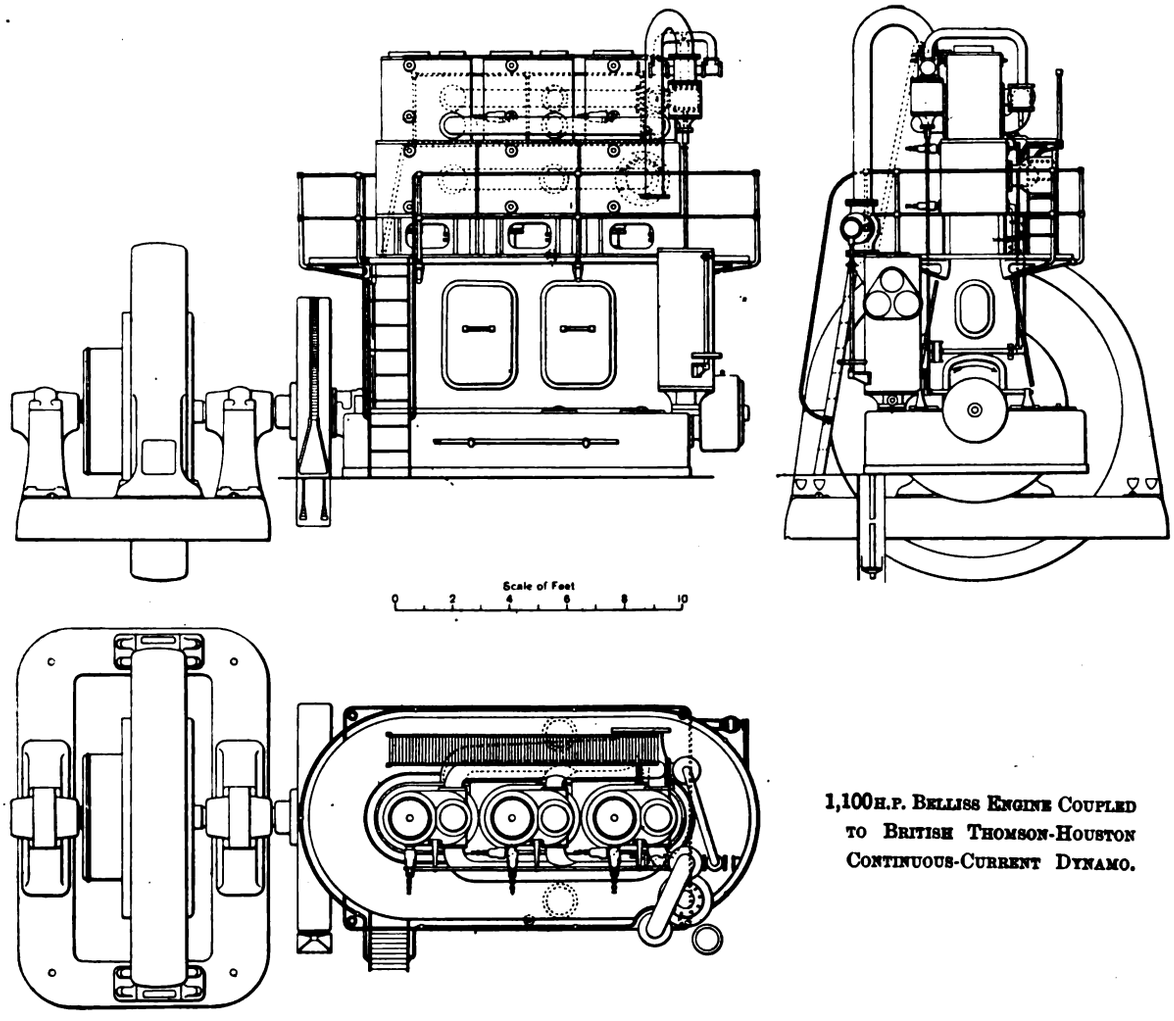


TEMPERLEY TRANSPORTER AT PORT DUNDAS STATION.

their patent safety explosion valve, which shuts the boiler off from the main in the event of a sudden drop of pressure due to the pipe giving out.

The feed range supplying the boilers is composed of two distinct lines of pipes running side by side along the whole length of the boiler-house, and each boiler is provided with an independent connection to each of these lines. The feed pumps are situated in the centre of the range, and consist of two double and one single direct-acting steam pump of Messrs. J. and A. Weir's make, having 7in. water pistons with a 21in. stroke. There is also a Hayward-Tyler three-throw ram pump driven through friction gear by a 12 H.P. series motor, the speed of the latter being regulated by altering the position of the field magnets with regard to the armature core while the machine is running; it is also arranged so that it can be run off either the 250-volt or 500-volt supply. The pump room is also fitted with a large hot well, a set of three gravitation filters, a large reserve storage tank, a feed tank, and duplicate connections from the city water mains. Opposite the pump room is the section containing the firemen's bathrooms and lavatories, which are all fitted with the most modern of sanitary appliances. The return connections from the boilers to the steam mains are 7in. mild-steel pipes with extra heavy flanges welded on, and the sections are bolted together with specially-machined and fitted mild steel bolts; one of these sections consists of an expansion loop of the same material as the pipes. The steam main consists of a 15in. mild-steel pipe with tee connections arranged so that the boilers and engines can be connected right through, or on to the common main as required. In this way it is possible to work a boiler and engine quite independently of the rest of the plant if necessary. These steam pipes were all constructed to Mr. Chamen's specification by Messrs. Stewart and Menzies. The main steam valves are of Messrs. Templer and Ranoe's make and are fitted with special steel seats.

Working platforms are provided for reaching the connections, and some idea of the size of the plant may be gained from the fact that there are, including those in the boiler house, 50 steam valves fitted already, none of them being less than 7in. Behind the boilers are the flues leading to the chimney, and a space with the necessary connection for the erection of fuel economisers should it be considered later on that any advantage would be gained by their use.



1,100 H.P. BELLISS ENGINE COUPLED TO BRITISH THOMSON-HOUSTON CONTINUOUS-CURRENT DYNAMO.

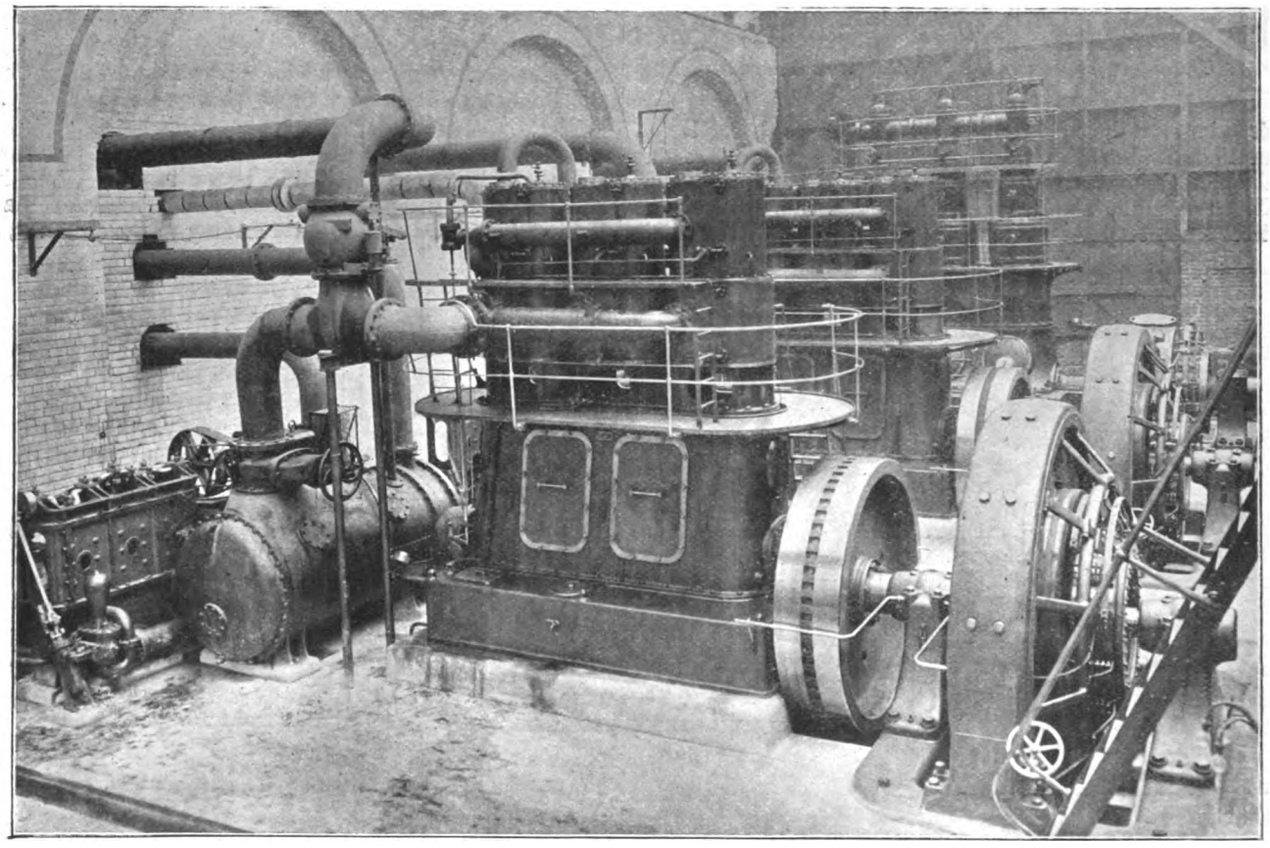
Engine Room Plant.—The machinery at present working consists of seven vertical direct-coupled sets with a combined

Digitized by Google

output of about 6,000 H.P. As has already been explained, the first portion of the plant was erected, owing to want of time, on the permanent foundations under a temporary wooden building. The present station was built round this, and when complete the wooden building was removed; while this was being done the plant installed was kept running up to its full capacity of 1,200kw. without a hitch, a fact which reflects greatly to the credit of Mr. Chamen and his assistants.

The four engines that were first supplied and run under these temporary conditions include, first, a 750 H.P. two-crank compound Ball and Wood engine. The engine has cylinders of 20in. and 44in. by a 24in. stroke, and runs at 150 revs. per min. The steam and exhaust valves are of the Corliss type, and the valve chests are placed on the top and bottom of the cylinder, each chest being divided so that one half contains the admission valve and the other half the exhaust valve for one end of the cylinder. The valves are right on the top of the cylinder covers and the ports are simply slots in the covers. The four admission valves are driven from one wrist plate and the four exhaust ports from another. The exhaust valves have a constant stroke, and the wrist plate is driven from an eccentric on the shaft by means of bell cranks and rods. The admission valves have a variable stroke, depending on the load on the engine. The sheave of the eccentric which drives them is not keyed on to the shaft, but is free to swing on trunnions, and the amount of its eccentricity or swing is controlled by the governor. This governor is a combined momentum and centrifugal governor, fitted with adjustable coach springs and weights, and mounted on the arms of the flywheel so that it takes up very little room. The gear will alter the period of admission on all four valves from zero to $\frac{3}{4}$-stroke, and the engine will take up some overload without any apparent alteration in the speed. Both cylinders are jacketed and there is an intermediate receiver fitted with a reheating coil. The lubrication is done by gravitation from tanks on the top platform, each bearing being fitted with an adjustable sight feed lubricator, and the oil after leaving the bearings is collected in a filter tank and again returned to the supply tanks on the platform. The connecting rods and crossheads are of the locomotive pattern. The main bearings are exceptionally long and are fitted with adjustable wedge packing, and the bedplate and back columns are of great strength and weight. This engine is coupled to two dynamos, built by the Walker Manufacturing Co. There is one machine on each end of the engine shaft, and they are compound-wound, eight-pole, 250-volt machines and are used as balancers, one being connected across each side of the three-wire system.

The next set is a 900 H.P. three-crank triple-expansion marine engine with combined surface condenser, built by Matthew Paul & Co. The air and circulating pumps are driven off the I.P. crosshead. The diameters of the cylinders are 17in., 25½in., and 38in. respectively, with a 30in. stroke, and the engine runs at 120 revs. per min. The governor is of the throttle type, and is fitted with suitable adjustment for varying the speed while running. Coupled to this engine is a 12-pole shunt-wound Schuckert dynamo with a smooth core bar-wound drum armature, whose end connections are arranged to assist the ventilation.



THE THREE 1,000H.P. SETS.

The remaining sets of the pioneer outfit are two single-acting constant-thrust enclosed engines, one of 200 H.P. and the other of 400 H.P., both built by the Mirrlees, Watson and Yaryan Co., of Glasgow. The smaller set is a two-crank two-cylinder compound engine with cylinders 14in. and 12in. diameter and a 12in. stroke, running at 380 revs. per min., the two cranks being placed opposite each other. The larger is a four-crank triple expansion engine with one H.P. cylinder 14in. diameter, one I.P. cylinder 22in. diameter, and two L.P. cylinders 24in. diameter, a 24in. stroke and a speed of 330 revs. per min. The four cranks are set so as to give balanced couples, the engines running under full load without any vibration. Each of these engines is coupled directly to a shunt-wound bi-polar Crompton dynamo, the outputs of these machines being 125kw. and 255kw. respectively, at 500 volts to 600 volts.

On the east side of the engine room are erected three fine 1,100 H.P. sets, each built to Mr. Chamen's specification. Two of these engines are of the well-known Belliss type, arranged for triple expansion working, having six cylinders on three lines—viz., one high pressure, two intermediate pressure, and three low pressure, the high and intermediate pressure

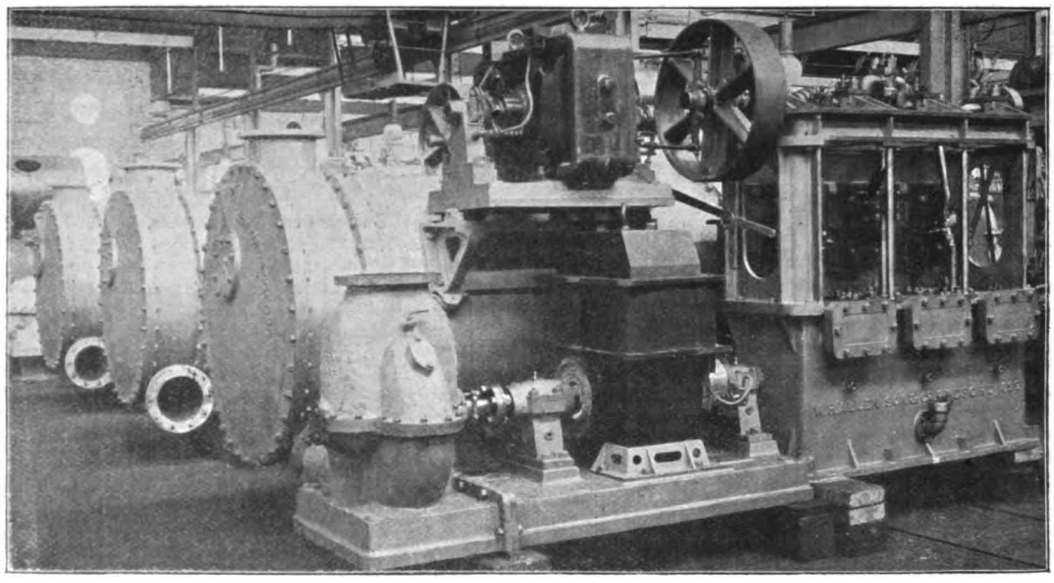
Digitized by Google

cylinders being placed above the three low-pressure cylinders. Each engine is capable of developing 1,100 H.P. as a continuous load when running at a speed of 230 revs. per min. with a pressure of steam of 180lb. per square inch and exhausting into the condenser. The engines are designed for an overload output of 1,500 I.H.P. under the same conditions, the object of this being to help the station over the peak, and as it would only be required for so short a time a slight loss of efficiency is of no importance. The slide valves are of the piston type, the high or intermediate pressures and low-pressure valves being placed on the same valve rod and operated by the same eccentric. Overload by-pass valves are fitted, worked from the governor, which enable them to maintain their rated speeds at overloads of 50 per cent. These engines are direct-coupled to British Thomson-Houston compound-wound multipolar generators capable of giving the full output of the engines at from 500 volts to 600 volts. The armatures are slot-wound and ventilated, and the field magnets are of cast-steel. Both of these dynamos, as also the third 1,100 H.P. machine, which is of Messrs. Crompton's make, are coupled to throw-over switches so that the series coils may be cut out and the generators run as shunt machines when desired.

The other 1,100 H.P. engine is a Willans three-crank triple-expansion engine designed to work economically at 1,100 H.P., but capable of being worked up to 1,500 H.P. if required, being fitted with automatic adjustable cutoff and by-pass valves for that purpose. There is no flywheel to this set, the armature of the Crompton dynamo to which it is coupled having been built extra heavily to take its place. This set probably represents the very latest practice in continuous-current dynamo building in this country. The field magnets are 12-polar, of cast steel, with laminated poles. Series coils are wound on an insulating frame so as to leave a clear air space between the shunt and series windings. The armature core is slotted and ventilated. Aluminium brush-holders are fitted, and ample commutator surface allowed. The outer bearing is of the adjustable self-aligning and self-oiling type. Our illustration shows the three 1,100 H.P. sets; a general view of the engine room was given in our last issue.

Condensing Plant.—For dealing with the exhaust steam from the enclosed sets described above, five sets of independent surface condensers have been installed. These have been built and erected complete by Messrs. W. H. Allen, Son & Co. Each set is capable of dealing with 27,000lb. of steam per hour. The elements of each set consist of a surface condenser, a three-throw Edwards' air pump and a centrifugal circulating pump, each of the pumps being driven by an electric motor. The shells of the condensers are of cast-iron, cylindrical in form, fitted with branches for the exhaust, the circulating water inlets and outlets, and the air pump suction, and with brackets for carrying the motor for driving the air pump. Each condenser has a cooling surface of 2,550 sq. ft., the tubes being of solid-drawn brass fixed into rolled naval brass tube plates by means of screwed ferrules and tape packing. These ferrules are provided with lips to prevent the tubes from slipping out of place, while allowing sufficient play for side expansion.

The air pumps are designed to run at 160 revs. per min., and are geared by Hollicks' gear to the 30kw. Allen motors. Each pump has three barrels 12in. in diameter by 12in. stroke. All liners and working parts and valve seatings are of brass, the casing of the pumps being of cast-iron. The pumps are driven by an overhead three-throw crank shaft carried by a neat entablature. A small water pump for dealing with the hot well water is driven from an overhung crank on the end of each air-pump crank-shaft. The air pumps have an effective displacement of 2·36 cubic ft. per revolution. The circulating pumps are of the "Conqueror" type, having cast-iron casings provided with suction and discharge branches 11in. in diameter, the diameter of the impeller being 17in. Each pump spindle is directly coupled to the motor shaft and stands under the bracket carrying the air pump. When dealing with the full load the air pumps require about 10 amperes at a voltage of 520.



ALLEN CONDENSING PLANT.

The exhaust connection from every engine terminates in a tee piece, one branch of which passes down to the condenser and the other upwards by way of a Blake and Knowles automatic relief valve to the atmospheric exhaust. The pump motors are capable of exact regulation, and the whole plant runs remarkably smoothly and with the minimum of attention.

Balancer, Booster, &c.—In the central portion of the engine room are placed the motor balancers and the boosters. The first-named consists of a Bruce-Peebles four-pole 250kw. motor-driven dynamo and a 50kw. motor-driven Silvertown bi-polar set. The latter is compound-wound, and capable of dealing with an output of 150 amperes at 230 volts to 300 volts at a speed of 650 revs. per min.

For charging the batteries, two sets of motor-driven boosters have been provided by Messrs. Mavor and Coulson. The motors are shunt-wound machines, and take current directly from the station 'bus bars at 500 volts to 600 volts, and the boosters have an output of 225 amperes at 20 volts to 160 volts. They are separately excited at 350 volts and run at 850 revs. per min. The armatures are wound on Sayers' patent system, and carbon brushes are fitted.

The motors distributed throughout the buildings have in most instances been noticed in connection with the plants that they are driving. The power transmission installation is somewhat extensive, as at present there are 16 motors used for various purposes, all running off the 500-volt mains. A

End Elevation of Front and Back Panels.

GENERAL ARRANGEMENT OF THE FEEDER SWITCHBOARDS ON THE GALLERY.

Switching Gear.—The general arrangement of the Port Dundas switchboards and switching gear does not follow the usual practice of bringing all the dynamo panels and feeder panels

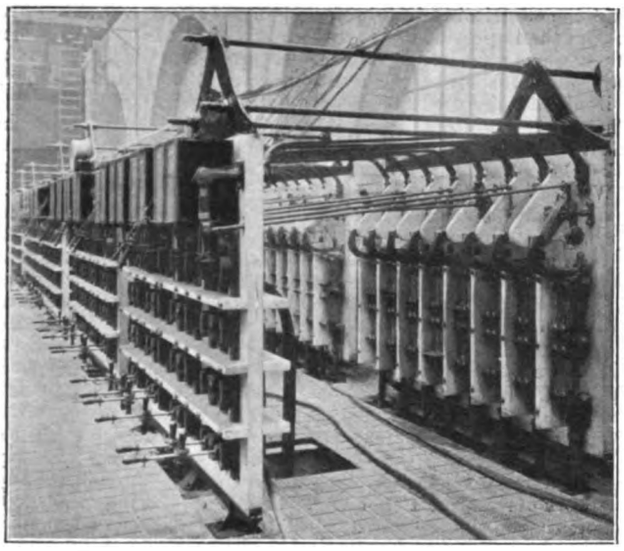
floor level in the engine room, underneath the switchboard gallery, each pair of panels being opposite its own dynamos. The other part is the "feeder panels," which are placed in a

Digitized by Google

gallery running parallel with the machines for the whole length of the engine room.

Each dynamo, as we have said, is provided with a separate positive and negative panel, consisting of massive polished slabs of white marble, mounted in a steel frame bolted to the floor. The positive panel is fitted with an emergency switch, a zero automatic cut-out, duplex fuse, and a four-way plugging and switching device. The negative panel has a similar set of apparatus, except that the zero cut-out is replaced by a Kelvin indicating and recording ampere gauge. These latter instruments are similar to the "feeder log," described further on, in the general construction, but they are current measuring instruments only. The panels for the three large sets are by Cowans Limited, and for the other by Messrs. Crompton and Co.; those for the steam balancer being manufactured by Messrs. Laing, Wharton and Down. The three large sets are fitted with Andrews' patent return current cut-outs. The recording instruments on all the panels are by Messrs. James White.

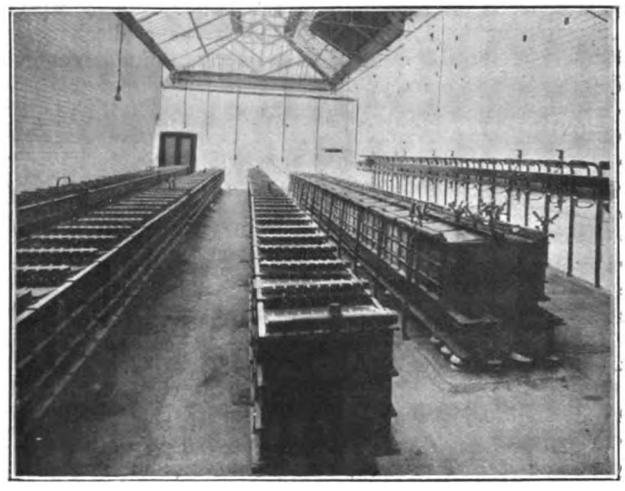
Underneath the switch gallery and above the dynamo panels, which are all connected to them, are run four sets of massive copper 'bus bars, and by means of the four-way plug switches any machine may be switched on to any set of these bars. These bars run from end to end of the entire engine house. The first 'bus bar in each case consists of six sections, the bottom section being 4in. broad by 1in. thick, and the top



View of Feeder Panels from one end, showing Front Panel on Left, and Back Panel on Right Hand Side.

five sections being 4in. by ¼in., thus giving a total sectional area of 14 sq. in. on the main positive and negative bars. The six sections are separated from one another by copper washers ¼in. thick and fastened together with steel bolts. The remaining three 'bus bars on each side are each formed of two sections, 4in. by 1in. and 4in. by ½in. The binding bolts are left long enough in all cases to take five more ½in. bars which will be added as necessity arises. The 'bus bars are erected in 22ft. lengths, and connected together by thin U-shaped copper bars which serve as expansion joints. The present length of 'bus bars amounts to 216ft. Provision is also made for additional lengths of bar for further extensions. All the copper for the 'bus bars was supplied by Elliot's Metal Co., and their erection has been carried out by Messrs. Mechan & Sons.

Connections from these 'bus bars are taken to those mounted on the back of the feeder panels which are erected on the gallery. The feeder panels are divided into sets, supplying eight pairs of feeders, and arranged in two rows one behind the other, and 6ft. 6in. apart, the positive panels for each set of eight feeders being next to the corresponding negative panel, as seen in the illustrations. In this way the positive and negative connections are in all cases only 10ft. apart, and the panels of like polarity stand in front of one another. In the present portion of the building six sets of feeder panels are being installed, supplying 48 feeders. Three of these sets of panels were supplied and erected by the Holland House Electrical Manufacturing Co. of Glasgow, and the other three by Messrs James White. The feeder panels consist of massive polished white marble slabs carried in steel frames bolted to the gallery floor, and the fittings and general construction are of a very solid and substantial nature. The mountings of the negative and positive sides are distinguished by the use of blue and red enamel on the surfaces that did not require to be otherwise highly finished. The back panels receive one terminal of the 1 sq. in. triple concentric feeder cables, and connect them through a duplex fuse to a quick-break main switch; thence across by a bare overhead copper conductor to the front panel through a recording feeder log (marked A in the lower illustration on page 810), devised by Mr. Chamen to keep a record of the load on the feeder and the pressure at the feeding point; from this log the current passes to a vertical plug bar through which the terminal of the feeder may be connected to any of the four 'bus bars mentioned in connection with the machine panels. The other terminal of the feeder is connected to the other pair of panels in the same manner. The middle wire (*i.e.*, the outer conductor of the triple concentric cable) is connected to a special set of panels common to all the feeders. This set of panels is placed in the centre of the gallery, and was manufactured and erected by Messrs. James White. The earth connection from the middle wire to the earth plates is taken through a recording ammeter fitted with an automatic short-circuiting device which comes into action when the leakage current exceeds a certain predetermined amount.



Battery Room.

The panels are uniform in size, being 5ft. 6in. high, 4ft. 4in. wide, and 3in. thick, and all are provided with marble shelves or partitions, which project sufficiently to prevent accidental contact being made from one to the other. The mountings of the panels forming the front row are uniform with one another, and in each case consist mainly of four vertical feeder bars, which can be joined up by means of plugs in the form of S switches to any of four horizontal bars, on the back of the panels, which are fed from the main 'bus bars laid below the gallery. An expansion joint is used to connect the bars on one panel to the corresponding bars on the adjoining panel. In the case of the panels manufactured by the Holland House Company the vertical feeder 'bus bars are of single forgings, complete and without joints of any kind; Messrs. James White's panels, on the other hand, have the contacts silver-soldered on to the vertical bars. Between each pair of vertical feeder bars there are four blocks of forged copper, which are joined through the marble to the horizontal bars on the back, the S switch plugs being used to connect these blocks to the vertical feeder bars. Carbon pieces are fitted to the blocks at the sparking points to enable the circuits to be broken at full load (1,000 amperes) without injury.

The Kelvin feeder log referred to gives a continuous record of the current going out on a feeder and the pressure at the

Digitized by Google

feeding point. The solenoids of these instruments are of Lord Kelvin's latest form, made from high-conduction copper tubes, cut with radial slots, and put together in such a way that the axis of the solenoid is exactly the axis of the field. A sufficient number of turns are provided to give an exceedingly intense field. The case has been specially designed for convenience in changing the record sheets, refilling the pens, &c. The clocks on these instruments are all synchronised from a handsome regulator erected on the feeder gallery, each instrument being fitted with electromagnetic mechanism for rotating the recording drums, and the mechanism is actuated every 30 seconds by a relay controlled by the regulator. The main switches enable each feeder circuit to be controlled separately, and are quick break in action with quick-break carbon sparking pieces. The movements of the switches are effected by steel levers and connecting rods, which latter are geared with lever handles, each having a locking device for the "off" and "on" position mounted on the face of the front row of panels. This arrangement enables the attendant to manipulate the switches from his usual position on the gallery. The duplex fuse apparatus consists in each case of a forged copper link which acts as a change-over switch, thus enabling either of the two fuses to be short-circuited or brought into circuit at will.

Battery Installation.—Running parallel with the engine room and one on each side of the tower containing the vestibule, engineer's office, test room, &c., are the positive and negative battery rooms. These have been supplied by the Tudor Accumulator Co., and contain 335 cells, arranged in two sets on the 500-volt three-wire system. There are 25 pairs of regulating cells on each half of the battery. The capacity of the battery is 1,100 ampere-hours at a discharge of 150 amperes, and the cells can stand a maximum discharge of 250 amperes. In connection with these batteries, one of the most noticeable features is the entire absence of all perishable material in the construction either of the stands or boxes. The stands themselves are composed of rolled steel girders, mounted on the Tudor Company's large porcelain insulators, lead washers being used to bed the girders fairly on to the insulators in order to protect them from the attack of the acid spray. The girders are covered with sheet lead; the cells themselves stand on heavy glass slabs which themselves are insulated from the girders with the ordinary glass oil insulators. The boxes are worthy of special note; Mr. Chamen objected to lead-lined wood boxes, on account of the perishable nature of wood, and as, of course, solid lead boxes of this size would have required to be so very heavy that the price would have been prohibitive. After several experimental boxes had been tried, the present type was adopted, which consists of a sheet-lead box inside a "crate" of cast lead, to which it is only tacked at the edges. Owing to the unsatisfactory wear of cement, &c., when exposed to acid, the floor is laid with pure Val de Travers asphalte. Another feature of the battery is the switch gear. Instead of taking the connections from the regulating cells into the engine room, or at any rate to a central position in the battery room, which would have involved the use of an excessive amount of copper conductor, Mr. Chamen has devised the following arrangement, which works exceedingly well, and was manufactured by Messrs. James White. The cells are arranged in three rows, and the row next the engine-room wall is composed of the regulating cells. Running parallel with these, and fixed to the wall, is a steel bar or rail in the form of an H-section girder. Attached to this rail are wrought-iron brackets, on which large gunmetal contacts are fixed, and insulated with substantial vulcanite insulators; the lower contact is in the form of a continuous copper bar, while the upper ones consist of a row of contacts each of which is connected to the terminals of the regulating cells previously mentioned. Another very novel feature of this regulator is the form of brush contact gear. This consists of a trolley carriage running on the H-section girder, already referred to, the whole length of the battery room. This carriage has three sets of contacts—the lower one makes continuous contact with the lower copper bar, which bar forms a constant connection between the battery and the middle wire, the two upper connections make connection with the row of fixed contacts. In order to prevent sparking the trolley also carries a substantial pilot contact and pilot resistance, so that one or other of the two moving contacts is always in circuit with the cells, and short-circuiting is provided against by the resistance being inserted between the two contacts. This trolley is moved by means of a wire rope passing round drums on a shaft at one end. The drums are geared to hand wheels near the dynamo switchboards in the main engine room, and large indicating wheels are provided showing at a glance the position of the contact trolley in the battery room. The contacts on the trolley are in the form of laminated rings making contact on both sides of the fixed contact shoe.

(To be concluded.)

ELECTROLYSIS OF UNDERGROUND METAL STRUCTURES.*

BY DABNEY H. MAURY.

Reports of electrolytic injury to water and gas pipes are rapidly accumulating from cities all over the United States, where the single-trolley system has been in use for any considerable length of time, and the subject is one of serious moment to every corporation or municipality owning underground metal structures of any sort. It is the purpose of the writer, after illustrating a few of the many instances of electrolytic injury which have come under his notice, to discuss the electrical resistance of the joints of cast-iron mains, and to point out the important bearing which this joint resistance has upon all the various remedies for electrolysis heretofore suggested, and to show from actual cases the results which must certainly follow if cast-iron mains are used to convey electric currents.

The writer has been, since March, 1893, engineer and superintendent for the plant now owned and operated by the Peoria Water Works Co. Early in 1893, the water company's street foreman, Mr. W. B. Norris, reported to the writer that extra strong lead service pipes laid under the street railway tracks were bursting with a frequency that was remarkable, and that the appearance of the burst pipes was unusual, and different from that of any pipes the foreman had yet seen. Electrolysis, as occurring in water and gas pipes was, at that time, almost unknown, and very little had been published, even in engineering papers, regarding it. The writer at once suspected, however, the cause of the breaks, and the foreman was instructed to give him prompt notice of every such break, so that he could personally inspect the pipe and note the circumstance attending its rupture. To keep better track of the injury printed tags were prepared, on which the attendant circumstances were noted whenever a pipe burst; the tags were signed by the superintendent, the foreman and the men assisting in the work of repairing the pipe. A sample of the pipe was saved for reference and the tag was attached thereto. Although a number of breaks occurred before these records were begun, and in spite of the fact that some intelligent labourers in search of lead for making joints in water mains appropriated and melted down a good many of our carefully preserved samples, records are still on file of 116 electrolytic breaks.

The bursting of service pipes continued with increased frequency, nearly always occurring on those pipes which passed under the railway tracks; for instance, on streets in which the mains were laid on or towards the south side of the railway tracks, 96 per cent. of the recorded breaks occurred in service pipes supplying the houses on the north side of the street and in pipes passing under tracks.

In investigating the cause of the destruction of our pipes, the query early suggested itself as to whether chemical action pure and simple could have caused the injury. To make clear the claim that the damage was done by the electric current, it seemed to the writer that some evidence should be found of redeposition of the metal supposed to have been removed from the pipes by the current. Our search for this additional evidence was soon rewarded, for early in March, 1894, we observed in the excavation made to renew a broken service pipe, that the lead taken away from the pipe was deposited in the form of glistening particles, or thin metallic coatings, on soil, sand and gravel, all through the adjacent earth, but above the pipe and in the direction leading from it up to the rails—the pipe at this point being shown by voltmeter tests to be electrically positive to the rails. In one excavation, where there was a well-defined wet streak along a fault in a clayey soil, the lead compound, afterwards identified by chemical analysis as sulphide, was observed along this wet streak as far as the sides of the excavation, or more than 6ft. from the pipe, the streak leading diagonally up from the pipe to the rails. A similar redeposition of the metal was observed in the case of

* Abstract of a Paper read before the American Water Works Association at Richmond, Va.

Digitized by Google

wrought-iron gas service pipes, and of cast-iron gas and water mains, the joints of the latter being surrounded in nearly every case by soil stained with oxide of iron, while immediately in front of the ring of lead in the joint would be found a bluish metallic discoloration showing the redeposition of the lead. The writer sent samples of the soil thus impregnated with lead and iron compounds to Messrs. Stone and Webster, electrical engineers and experts, of Boston, and to *Engineering News*, and to *Fire and Water*. The letters accompanying the samples, which were published in *Engineering News*, March 22, 1894, and in *Fire and Water* of about the same date, were, it is believed, the first published notes of such redeposition of the metals removed from underground pipes by the return street railway currents. On March 30, 1894, the water company's steel stand-pipe on the West Bluff burst, killing one person and injuring 15 others, one of whom died later from his injuries. Upon examining the wreck of the stand-pipe, the writer at once noticed a peculiar pitting of the inside of the vertical sheets, and the appearance of these pits was so different from that caused by any ordinary oxidation that he was soon almost positive that they were due to electrolytic action. A similar stand-pipe on the East Bluff was drained, and was found to be similarly pitted. The whole inner surface of the vertical shell appeared to be thickly covered with blisters resembling in outward appearance the tubercles sometimes found inside of old cast-iron mains. This blistered covering, which was almost as thin as paper, was composed entirely of oxide of iron, and on brushing it away with the finger tips, the black paint with which the stand-pipe had been originally coated would be found beneath it. The black paint was oftentimes almost unbroken, or, at least, very slightly cracked. When the paint was brushed off, the pit would be disclosed, considerably smaller in area than the surface covered by the blister. The surface of the metal in the pit was perfectly bright and clean and its fibre was clearly discernible. Many of these pits were more than $\frac{1}{16}$in. in depth. They were slightly more numerous in the West Bluff pipe than in the East Bluff stand-pipe, and were in both generally larger and deeper on the lower courses of the vertical shell.

Fig. 1 is from a photograph of the wrecked stand-pipe, the upturned corner of the torn sheet near the centre, showing the pitted appearance of the surface, the blisters having been, of course, shaken off by the fall of the metal and the metal itself having become somewhat oxidised before the photograph was taken. The two largest blotches are streaks of mud. Fig. 8 is from a photograph of a small sample of steel from the stand-pipe and shows the pitting in the sheets around the edges of the rivet heads.

FIG. 1.

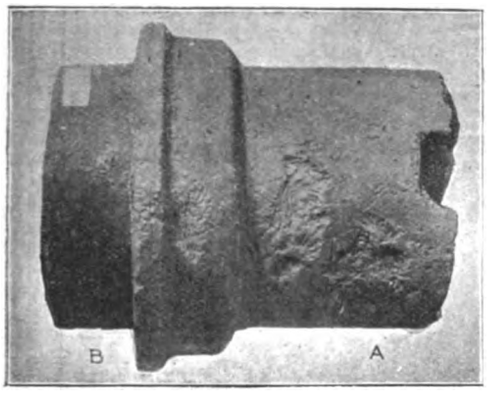


FIG. 3.

It seemed advisable to secure a thorough expert examination with a view to determining the cause, nature and extent of the observed pittings on the stand-pipes, and injuries to the piping system. Messrs. Stone and Webster, of Boston, were selected to make this examination. The work, in which the writer from time to time, assisted, covered seven weeks on the ground, and the report submitted by Messrs. Stone and Webster fully confirmed the suspicions that the pitting was caused by electrolysis, and established the fact that the entire piping system of the water company would be endangered by a continuance of the existing electrical conditions. The West Bluff stand-pipe was distant about 60ft. from the street railway line on Bourland-street. The East Bluff stand-pipe was about 700ft. distant from the railway line on Knoxville-avenue. Both stand-pipes were more than a mile from the power station and were negative to the rails. The electrical examination relative to the stand-pipes was conducted mainly at the East Bluff stand-pipe, which was still in service. A flow of a part of the current from the railway line was clearly traced through the earth to the anchor bolts which held the stand-pipe to its foundation, as shown in Fig. 5, up these bolts and into the steel of the shell, and through the shell and from its inner surface to the projecting section of the 16in. flanged cast-iron pipe which served as both inlet and outlet, and which connected the stand-pipe to the water mains. The current was then traced along this pipe and along the mains to the power station. The deflections of the voltmeter needle were clearly traced to the railway current, being especially influenced by the one or two cars on the line beyond the stand-pipe on Knoxville-avenue, and when the cars stopped running at night the movement of the needle ceased. Where the current left the inner surface of the shell to pass through the water to the inlet pipe it made the pits already described.

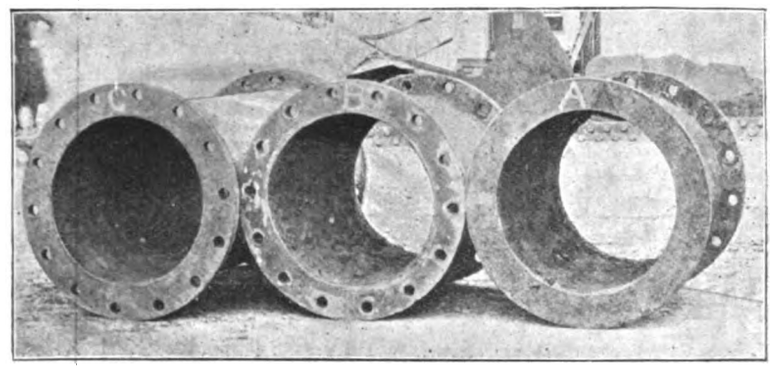

FIG. 2

Fig. 2 is from a photograph showing the interior surfaces of three sections of this inlet pipe, marked A, B and C respectively, the positions occupied by these sections originally being shown by the letters A, B and C in Fig. 5. An examination of the photograph shows the strongly marked and numerous pits which were found inside the sections A and B, while the inner surface of the section C was found to be practically as smooth and perfect as though new. When the condition of the inside of these three sections of pipe was first noted, it seemed hard to understand why A and B should be pitted, while C was unaffected. A closer examination, however, showed that in the flanged joints between the bottom sheet of the stand-pipe and A and B, respectively, corrugated copper gaskets were used, while the pipe B was separated from the pipe C by a thick rubber gasket; and that under the nuts and heads of the bolts holding the flanges together there were grummets or wrappings of cotton wick soaked in tallow. The result of this arrangement was that the current which entered A, after passing through the

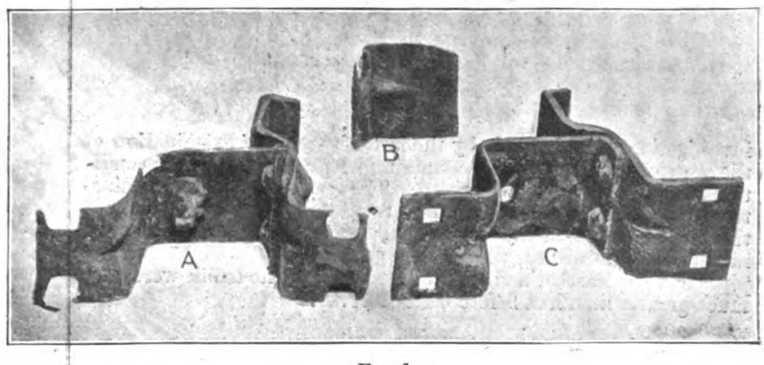

FIG. 4.

Digitized by Google

water from the inner side of the shell of the stand-pipe, and which was trying to return along the inlet pipe and water mains to the power stations, encountered at the joint between B and C the rubber gasket and the grummets. The effect of the gasket and grummets was to practically insulate the section C from the sections A and B, and as none of these pipes were in contact with the ground the current was compelled to leave the pipes A and B and travel through the water or along the slimy coating of oxide on the inside of the pipes around the joint between B and C, in order to continue

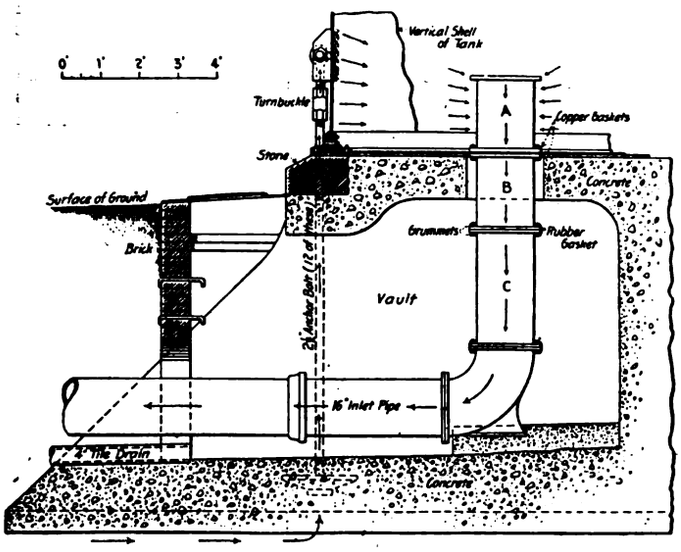

FIG. 5.

on its journey. As the current was not leaving C this pipe was not injured, but the current, in leaving the inner surface of A and B, did pit them, as shown in the photograph. These stand-pipes and the inlet pipes were negative to the rails, and are striking examples of electrolytic pitting under such conditions.

Early in 1898, Prof. D. C. Jackson, of the University of Wisconsin, and Messrs. Stone and Webster were requested to supplement the

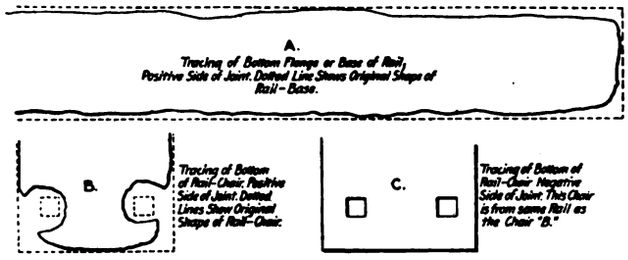

FIG. 6.

investigations already made by the latter by another examination of the system, with a view to ascertaining whether the electrical conditions reported in 1894 still existed. The result of all these examinations and of those made, from time to time, by the writer, showed that the differences of potential between mains and rails had increased rather than diminished, while the number of breaks in the service pipes and the number and extent of pittings in the mains were very much greater than had before been observed.

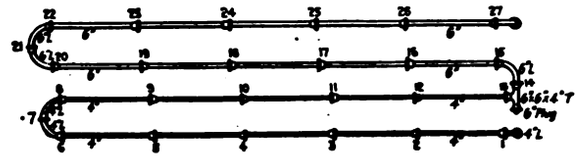

FIG. 7.

With a view to further proving that the injury done to the cast-iron mains and service pipes was caused by the electric current, samples of the graphitic substance dug out from the pits in the mains, and of the scale or incrustation adhering to the mains over the pits, and of the soils at various distances from the mains, and similar samples taken from the neighbourhood of the lead service pipes, were sent to the University of Illinois, where they were analysed by Prof. Arthur D. Palmer. Samples of ordinary soils, unimpregnated by the metallic compounds from the pipes, were also analysed. These analyses showed that there was nothing in the soil which, except for the action induced by the electric current, could injure the pipes, while all of the conditions, as found by chemical analysis of all the samples submitted to Prof. Palmer, were exactly such as would be caused by the presence of the currents complained of.

In 1899, a series of tests were made by Mr. A. A. Knudson electrical engineer, of New York, in conjunction with the writer, at the site of the fallen West Bluff stand-pipe, in order to still further prove

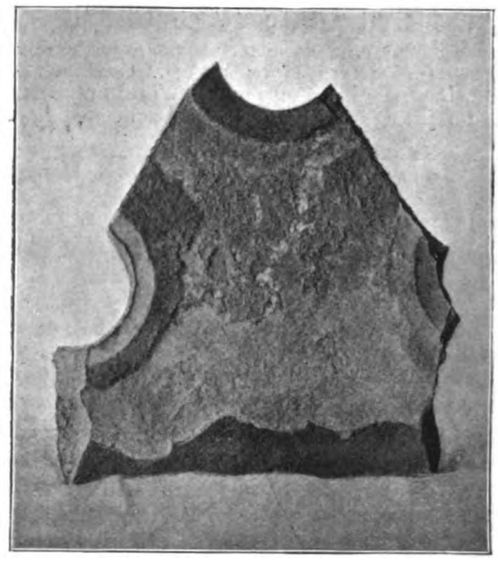

FIG. 8.

that when that stand-pipe was in service, there was an actual flow of current in the manner already shown by the previous tests at the East Bluff stand-pipe by Messrs. Stone and Webster. The anchor bolts were still in the foundations, but the shell of the stand-pipe, as well as the 16in. inlet pipe leading thereto, had been removed. It was necessary, therefore, in order to reproduce, to some extent, the actual electrical conditions that had previously existed, to connect a wire from the ends of the anchor bolts to the 16in. water main in front of the stand-pipe. By connecting in a voltmeter on

FIG. 9.

this wire the variations of potential between anchor bolts and the water main were observed, and by replacing the voltmeter by an ammeter, the actual flow of current was measured. This current was clearly and positively identified as caused by the street railways, and the result of these tests fully confirmed the statement in the reports of Messrs. Stone and Webster, that the pits in the shell of the stand-pipes had been caused by the street railway current.

The joints of cast-iron water mains often offer, as already stated, considerable resistance to the passage of the electric current, and the

Digitized by Google

reason for this resistance is apparent, when the construction of these joints is studied. Cast-iron water pipes are coated inside and outside with a preparation of coal tar that is an insulating material. In making a lead joint, the spigot end of one pipe is inserted in the bell end of another pipe and pressed home until it touches the shoulder in the bell. The spigot pipe is centred carefully, so that the annular space designed to hold the yarn and lead may be of equal width all around. The yarn is then rammed in home against the shoulder and holds the spigot in the centre of the bell. There can thus be no actual contact between the two pipes, except where the very end of the spigot abuts against the shoulder of the bell. As both spigot end and shoulder are simply rough castings and are not turned, it follows that they are rarely in mechanical contact at more than two points, and on curves they can only touch at one point. In fact, it is frequently true that after the spigot pipe is once shoved home against the shoulder of the bell, and then released, it works away in the subsequent handling and yarning and oftentimes is not in contact with the bell at all. Even if the two pipes were in actual mechanical contact, the electrical contact would be poor, by reason of the two intervening coatings of tar or asphalt. In that portion of the joint occupied by the yarn, there is no contact between the two pipes, and they are at this point fairly well insulated by the yarn itself, as well as by the two coatings. The rest of the joint is filled with lead, which is a conductor of electricity, but in between the ring of lead and the bell outside of the lead and between the lead and the spigot on the inside, are the two tar coatings which materially interfere with the electrical contact between the two pipes. As it had been stated that the tar coating is completely consumed and burnt out by the heat of the molten lead when a joint is poured, the writer caused a joint to be poured and calked in the usual manner, and then had the bell sawed into three pieces, so that it could be taken off the spigot. It is needless to tell men who have had experience in laying and taking up water mains that the inner surface of the bell showed that the coating was entirely unimpaired by the heat. Measurements were made by the writer in 1898 to determine the amount of resistance offered by the joints in cast-iron water pipes, and also to ascertain whether the pipes themselves showed any pitting as a result of this resistance. A large number of these examinations were made during 1898 and 1899, and in every case the pipe which was of the higher potential was found pitted near the joint, while the pipe of the lower potential, or that into which the current was flowing from the other pipe, showed much less electrolytic injury. To further test the joint resistance and to determine, if possible, the influence of different methods of caulking as affecting this resistance, the writer, in conjunction with Prof. Jackson, caused a line of 6in. and 4in. pipe to be laid and supported on wooden blocks, so as to insulate it from the ground, as shown in Fig. 7. There were 27 joints in all. The pipe was new, and had not been previously used. The caulker was instructed to drive up the lead hard in one-third of the joints, and to caulk these joints in every way in the best possible manner, just as though the pipe were expected to stand the heavy pressure of the Peoria Water Works Co.'s system. Another third of the joints was caulked not quite so hard, while the remainder were purposely only lightly driven up, the work being done as though carelessly, or by a bungler. A current of known strength was passed through the pipes, and the drop of potential around the joints was measured at points 1ft. apart, and was compared with the drop of potential in length of 1ft. of continuons pipe. These measurements were made at different times; first by Prof. Jackson and the writer, then by the writer alone, and later by Mr. Knudson and the writer. The resistance of the joint was found, as shown by the table, to be from a few times to several thousand times that of the same length of continuous pipe, and this joint resistance was in no way affected by the manner in which the lead was driven up in the joint, some of the joints on which the best caulking was done showing the highest resistance. The usual depth of lead in a joint in a cast-iron pipe is about 2½in., but assuming the length of the joint at 4in., the joints in this line offered 89·2 per cent. of the total resistance of the whole line, or on the average the resistance of a joint was 227 times the resistance of 4in. of plain pipe. In making this calculation due allowance has been made for the fact that the points of measurement around the joint were 1ft. and not 4in. apart. These observations, taken over a period of about 11 months, also showed that the resistance of the joints increased rapidly with age.

In Kansas City Prof. Lucien I. Blake, of the University of Kansas, has recently made a number of tests of the joint resistance in cast-iron mains. He found the joint resistance in three lengths of 6in. pipe to be about 96 per cent. of the total resistance of the pipe and joints together; the joint resistance in the 58 joints of 687ft. of 6in. pipe which has been 13 years in service was found to be 96·2 per cent. of the entire resistance of the line; the joint resistance of 38 joints in 399ft. of 20in. pipe was 88·2 per cent. of the total resistance of the line; and the joint resistance in 400ft. of 36in. pipe was found to be 96·7 per cent. of the total resistance of the entire line. Mr. Knudson found in Albany a pipe joint which showed a resistance 1,000 times greater than the resistance of an equal length of the plain pipe. The injury caused by resistance at the joints is not so rapid at any one spot as the injury where the current leaves

the pipe for the rails in the positive area, only because all of the current carried by the pipe does not flow around the joint. But one ampere of current, leaving the pipe for the power house in the positive area, pits the pipe but once at that point; while one ampere of current flowing along the pipe and around joints in either the positive or negative district, pits each length of pipe near every joint, where it leaves it to flow around the joint; so that the total injury caused by this ampere is cumulative, and may be, in the aggregate, hundreds of times as great as the damage caused by the same ampere of current where it permanently leaves the pipe.

The effect of the current on the rail joints of a single trolley system is similar to that on the joints in the water mains. Within the past three years the writer has examined many hundreds of rail joints, and it was always easy to tell from the appearance of the rail ends, and of the chairs, when the rails were laid on chairs, which way the current was flowing. The end of that rail which was next to the power station would show little or no injury, while the end of the other rail, or that having the higher potential, was invariably pitted. Fig. 6 is reproduced from tracing from the bottom flange or base of such a rail end (and also from two rail chairs), the solid line showing the shape when the tracing was made, while the dotted line shows the original shape of the rail when it was new and before it had been eaten away by the current. Fig. 6 also shows the bottom portions of two rail chairs. The chair B was taken from the side of the joint away from the power station. The dotted lines show its original shape. The chair C came from the other end of the same rail, on the negative side of the joint, and shows no perceptible injury. Fig. 4 shows two rail chairs and a fragment of a third chair secured by Mr. Knudson and the writer. The chair, A, was a sample of a large number of similar chairs on the high potential side of the joint, and its thin and wasted appearance is plainly shown. The fragment B was broken by hand from another similar chair. The chair at C was from the same piece of roadbed, and is a fair sample of a number of chairs observed near the low potential side of the joint. This chair, as the view shows, is almost a good as new. The soil around the outside of a water main offering an easier path for a current than the water or slime on the inside, outside pittings are more numerous and generally deeper, and they are much more easily observed. The pits on the outside may be caused either by current which leaves one length of pipe to go around a joint into the next length of pipe, or by current permanently leaving the main for some other conductor of lower potential, such as rails, or wires leading to the dynamo; but the inside pits cannot be caused by anything except resistance in the line of pipes itself at the joints, as nothing else could make the current leave the metal of the pipe and travel through the water. Opportunities for observing these pits have heretofore been rare, as the action is naturally slower inside the pipe than outside, and as it is necessary for some one familiar with the effect of electrolysis to be present and actually,

Digitized by Google

examine the pipe at the time when it is removed in order that the pits may be identified. The pittings in the 16in. inlet pipe to the West Bluff stand-pipe, observed in March, 1894, and inside pittings found by the writer in a 20in. cast-iron main in 1896, are believed to be the earliest examples of this injury noted, but numerous instances have since been reported. Fig. 3 shows a joint of a 12in. cast-iron main on which the current was flowing from A to B. The very serious outside pittings, nearly ½in. in depth, are plainly shown on the pipe A, while the pipe B, on the other side of the joint was, near the joint, almost uninjured. The surface of the lead in this joint was deeply pitted in places and so much of the metal had been removed that the marks of the caulking tool all around the joint were entirely obliterated. The pipe A was also pitted in a number of places on the inside, while no pits were found on the inner surface of the pipe B near this joint. Mr. A. A. Knudson found deep outside and inside pittings in Albany, in 1899, as shown in the view, Fig. 9. Prof. Blake, from recent examinations in Kansas City, writes as follows: "A 12in. pipe running at right angles to an electric railway, and which was negative to the rails, was found to be carrying a current of varying strength and delivering it into a 36in. main some 750ft. distant. Electrolytic pittings were found on many sections near the joints, only on the positive side, where the current was shunted around the joints. Some of the pittings were ½in. deep. The interior of the pipe could not be examined. Again a length of 6in. cast-iron main was taken up in another part of the city and internal electrolytic effects were apparent near the joint. A chemical analysis of the material dug from the pits gave 22·3 per cent. graphite, 49·7 per cent. iron. A second length was removed and broken into, and a fresh fracture revealed the internal electrolysis by the discoloration of the iron where the pitting was taking place, and which was already ½in. deep, beginning from the inside. A number of similar cases were discovered, and are convincing proof that cast-iron mains cannot convey currents without electrolytic damage when those mains form part of the return circuits of electric railways."

Within the past few months the writer had occasion to remove from the ground a 16in. cast-iron main. This main was negative to the rails, and was nearly 2 miles from the power station. It lay at right angles to the tracks, and the portion removed was distant at its nearest point about 150ft. from the rails, and at its further end, 570ft. from the rails, there being 420ft. of pipe removed. Measurements with voltmeter and ammeter showed a current flowing along this pipe from the rails towards the wet soil of the river bank, in which the further end of the pipe was buried. Every length of pipe showed electrolytic injury. In one pipe the bead in the spigot end had been eaten off for two-thirds of the circumference of the pipe, and in one place the entire thickness of the pipe was eaten out for nearly an inch in depth from the end. There were both outside and inside joint pittings, always on the positive side of the joint, and no pits at all could be found anywhere else on this pipe.

In a recent Paper Prof. Blake states that observations and experiments prove that the effects of electrolysis upon water pipes are not limited to the so-called "danger areas," or districts in which the pipes are electrically positive to the rails. He goes on to say: "Resistance at the joints in cast-iron pipe is sufficient at most joints to shunt a portion of any current allowed in these mains, around the joints through the soil outside or water inside, or through both. Then on the positive side of joints, the effects of electrolysis, both external and internal, are to be apprehended." Prof. Blake then gives in detail the tests previously referred to as made by him to determine the joint resistance, and closes by giving the forcible and convincing examples already quoted of the disastrous results of allowing cast-iron mains to convey electric currents.

It must be clear to anyone who has seen the evidence of injury caused by the return currents, and who has studied the effects on the water mains at the joints, or at any other point where the current, once on the pipe, must leave it, that the owners of such pipes can do nothing to prevent the injury. Street railway companies have frequently recommended that the pipes themselves be connected by wires to the negative 'bus bar of the generator, or to the rails at various points, or to overhead or underground return feeder wires—thus diminishing the resistance of the pipe system as a conductor, and lowering the potential of the pipes usually in what has been termed the "danger district" or the region where the pipes are shown by voltmeter to be positive to the rails. But all such methods contemplate using the pipes to convey the electric current, and they all invite more current to the pipes at some part of the system. It would undoubtedly be a fine thing for the railway companies to have the conductivity of the pipes on which they already rely largely for the return of their current still further increased. It would mean smaller coal bills in the power station and less outlay for construction and maintenance of their own return circuit. It would, also, apparently lessen the rapidity of injury to the pipes in the "danger district," and, by stopping temporarily the number of actual breaks at the points where they have been occurring with greatest frequency, it would stave off the day of reckoning with the pipe owners. But the general pipe system would be carrying much more current, and, as the pitting goes on, at or near the joints, whenever a main is carrying current, either in the positive or negative districts, it would mean that while the injury in the "danger district" would not be so rapid, the whole system would be much more generally attacked, and that by the time a bursting pipe at length called attention to the injury at some point remote from the power station, the entire pipe system would have been seriously injured. Equally impracticable and misleading are the suggestions for maintaining the pipe system at equal potential throughout, and for "insulating sections" or "insulating joints," some of which have been patented. The idea of these sections or joints, as advanced by their advocates, is to break up the metallic continuity of the pipe line and reduce its conductivity, and thus prevent its serving as a path which the return current would naturally choose. The effect of thus dividing a pipe system into a small number of sections would hardly be worth considering, as the ground itself is a good conductor, and the current would leave one section only to go to another, passing through the earth around the insulating joint just as it does around the lead joint in a cast-iron main. To entirely destroy the conductivity of the pipe line, it would be practically necessary to make it up entirely of insulating sections, which, as non-metallic substances are not generally recognised as good material for underground water pipes, and for other equally obvious reasons, would be absurd. The conductivity of the tracks may be, of course, increased by the use of heavier rails, heavier bond wires and improved methods of bonding, or by the introduction of welded joints, or by making practically continuous rails; but the continuous rail itself is at best but a palliative of the electrolytic injury. The rails are not insulated from the ground, and the pipes would still carry and be affected by a large portion of the current, as is clearly shown by numerous electrical surveys and reports of serious damage in cities where the best tracks known to modern science are in use.

In conclusion, the author recommends the double-trolley system, overhead, as at Cincinnati, or conduit, as in Washington and New York, as the only perfect method of keeping currents out of the ground and preventing electrolysis.

AN EXPLANATION OF A COMMON PHENOMENON NOTICED IN CABLE WORK.

BY H. G. BARWELL.

It has probably been noticed by every electrician who has been engaged in cable work that during the whole time a splice is being made sharp kicks are noticed on the galvanometer employed for the usual dielectric resistance test.

On a recent repair, while picking up to a fault, a watch was kept for it coming in by means of a current direct to line through a milammeter, to which was joined one side of a telephone receiver, the other side of the latter being connected through a 1 microfarad condenser to earth (as per Fig. 1). The current observed on the milammeter was 40 milliamperes. On commencing to pick up, the sound in the telephone was found to be intermittent—that is to say, there was alternate buzzing and silence, the cause of which I take to be as follows: The depth of water was 980 fathoms; 480 fathoms from the ship was a splice, type C to D, the latter type having each sheathing wire taped. The fault, which was two nauts beyond this splice, was caused by a wire of the type D having punctured the core at a bad twist, the iron wire remaining in the hole and apparently completely stopping any contact between the copper conductor and the water, as was shown by the fact that the resistance of the fault remained extremely steady at some 40 ohms and exhibited no signs of polarisation with either current. It was evident, therefore, that the fault was in no way responsible for the intermittent buzzing in the telephone, and that it was probably caused by the ship rising and falling on the fairly heavy swell and bringing varying strains upon the splice, which at the commencement of picking up was about midway between the surface and the bottom. On the splice coming over the bow sheave, the buzzing became considerably louder, and continued, without any intermission, until it had passed the jockey, when, on stopping the drum to cut the cable, the noise ceased entirely. Instructions were then given to get the splice on the drum and *worry* it, and then to lay it on the deck again. This operation was repeated several times, and on each occasion, the moment it was handled, buzzing

Digitized by Google

re-commenced, but stopped instantly on its being left alone. After cutting out the splice, its insulation was tested and found to be perfect, within the limits of observation. The telephone was then connected to the sea end containing the fault, and found to be absolutely silent, showing, as before stated, that the fault was in no way responsible for the buzzing. The milammeter meanwhile had remained perfectly steady at 40 milliamperes, exhibiting no signs whatever of any variation of the resistance in circuit.

This phenomenon appears to be of the same nature as that mentioned in my first paragraph; and I offer the explanation that it is due to small changes in the capacity of the cable

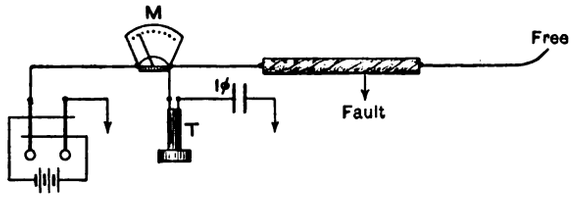

FIG. 1.

caused by variations in the resistance of the contact between the respective sheathing wires at a splice, these variations being due to the application of different strains or pressures, and that the effect is more noticeable when, as in the above case, one of the cables has each of its sheathing wires covered by a partially insulating tape.

As a proof of this the following experiment was tried: Six nauts of type E in one tank, and 17 nauts of type B in another, had their conductors joined together, and their sheathings brought into better electrical contact by means of connecting wires as shown in Fig. 2. On tapping the ends

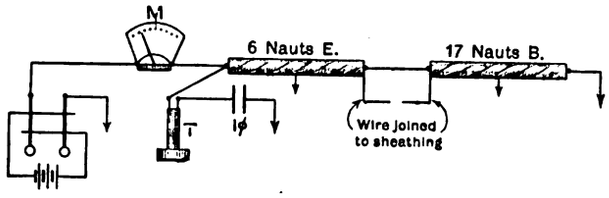

FIG. 2.

of these connecting wires together a very distinct tap was heard in the telephone, which was equally audible when no current was being sent through the cables. One of the wires was then connected to a file, and the other wire scraped over it, when it was observed that the sound in the telephone was very similar to that produced by handling a splice, being more of a buzzing than a distinct tapping. By this means Morse signals could be clearly read, although, as before mentioned, no current was being sent through the cables. The distant end of the type B was then freed, and a galvanometer put in place of the milammeter, and on tapping

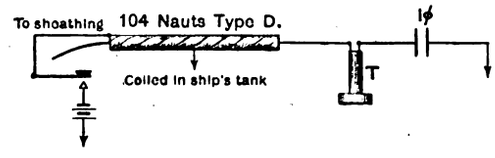

FIG. 3.

the ends of the wires together kicks, similar to those observed while a splice is being made, were produced on the galvanometer. This, I think, proves fairly conclusively that the kicks are due to changes in capacity. It will be seen from the above experiment how very minute the variations in the resistance of the sheathing are which disturb the surface charges, and cause these effects; as, in the above case, the two sheathings were already in good contact with each other through the ship's hull, before the ends of the copper wires were tapped together, and more especially so as a considerable portion of each length of the cable sheathing was devoid of any outer serving. These disturbances are, I think, caused as follows: When two lengths of cable are spliced together, they take up charges which vary according to the respective localities along their length, and possibly also in proportion to the size of their cores, and rates of absorption, &c. Now, if any alteration is made tending to improve or the reverse the connection between their respective sheathings, the *status quo ante* is not maintained, and a redistribution of the free potentials takes place, producing the sound heard in the telephone. The two following experiments are also of interest:—

A current was communicated to the sheathing of 104 nauts of type D coiled in the ship's tank, to the conductor of which a telephone was connected, as shown (Fig. 3). On depressing the key signals were distinctly audible whether the home end of the conductor was freed or earthed, no difference being perceptible when the telephone was connected as shown, or to the home end.

Fig. 4 indicates the connections in the next experiment. In this two 20φ condensers joined in parallel had one of their plates connected to the core of the 104 nauts of type D, and also to one side of the telephone, the other plate being joined to the lever of the key, the lower contact of which was in connection with the cable's sheathing, and the upper to the opposite side of the condenser, so that the latter was short-circuited after each contact. With this arrangement sound signals were quite audible, but not so strongly as in the previous experiment; if, however, the telephone was connected to the far end of the conductor, nothing whatever could be heard. This effect was probably in greater part due to charges induced in the cable from the rolling of the ship, which were imparted to the condenser on depressing the key.

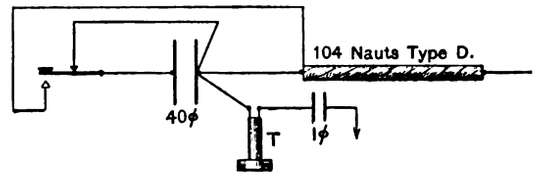

FIG. 4.

These induced charges may also possibly play a part in the first experiment with the two lengths of cable, but I think there can be little doubt that the sounds are mainly due to the improvement in the contact between the two sheathings in this particular case, and the resulting redistribution of the free potentials.

From the foregoing it will be seen that by joining a telephone up as in Fig. 1, a splice can be heard when the ship is approaching it picking up, provided there is no other disturbing influence at work, such as a variable fault in the circuit; and knowing the depth of water, and noting the first indications of the splice being disturbed on the telephone, one may form a fairly approximate estimate of its distance from the ship.

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny
Editorial Publishing and Printing Offices,
2 & 3, SALISBURY COURT, FLEET ST., LONDON.
Telephone: 949 Holborn. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to THE EDITOR.

All letters for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

New Volumes of "THE ELECTRICIAN" *commence in April and October.*

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of THE ELECTRICIAN" *Printing and Publishing Company, Limited. The well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. ELTON YOUNG, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. FISHER and J. C. H. DARBY. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. PHILLIPS. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints" on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. FISHER. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. RAPHAEL. Price 5s., post free.

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by DR. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. Vol. II. Price 12s. 6d.; post free, 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By DR. J. A. FLEMING. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. New Edition. 93 original illustrations, price 6s.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. New edition. Price 10s. 6d., post free; abroad 11s.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d. post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d.; post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free 2s. 2d. each; strong cloth 2s. 6d., post free 2s. 9d. each. Single Primers 2d., post free 2½d.

WIRELESS TELEGRAPHY: SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES. By Dr. O. J. LODGE. New Edition. Price 5s. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, ELECTRIC TRACTION, TELEGRAPHS, TELEPHONES, &c. A. C. CURTIS-HAYWARD, B.A. To January, 1900. Price 3s. 6d., post free.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By FRANCIS JEHL. Price 10s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

THE ELECTRIC ARC.—By Mrs. AYRTON. This work is in the press and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. WADE. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. RAPHAEL. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

THE TELEPHONE.—By DANE SINCLAIR and F. C. RAPHAEL.

SPECIAL NOTICES.

NOW READY.—Vol. XLIV. of "THE ELECTRICIAN" (950 pages) bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of "THE ELECTRICIAN" (1878-1900) can now be supplied. These sets are very scarce, and early application should be made

NOW READY.—"THE ELECTRICIAN" READING CASE. Holds four copies of the Journal. Strongly made and corded for hanging. Price 1s.; post free, 1s. 4d.

THE THEORY OF ELECTRONS.

In our leading article last week we commented upon Prof. J. CHUNDER BOSE's Paper "On the Similarity of Effect of Electrical Stimulus on Inorganic and Living Substances," one of the most important communications made to Section A of the British Association at Bradford. To-day we shall consider the scarcely less interesting discussion on "Ions" which took up the greater portion of a day's proceedings in the same section. The electron theory was its prominent feature. What is an electron, and what are its properties? This, we conceive is the most pressing question at the moment for the physicist; and we hope that when the history of the development and growth of our ideas in this important branch of physics is written, as no doubt it will be, by some future WHEWELL of the twentieth century, the discussion which was opened in so masterly a manner by Prof. FITZGERALD will be found to have added materially to the progress of knowledge of this subject—to have added to it, if not by any new discovery, at least by what is of no less importance for discovery, the clearing up of our conceptions upon such matters, by separating the chaff from the wheat, by defining more clearly the horizon of our knowledge. Often the investigator, like a traveller in the desert, may have to wander far and wide in search of a solid fact upon which he may take his stand. And oftener still some mirage is ready at hand to delude him and make him believe he has reached truth that is indeed far away. He needs the critical mind, and the old experienced hand to draw him back, as it must itself at times have been drawn back. This is the function which discussion at such meetings as the British Association performs, and this we believe is the service which the critic renders to science.

We wonder which of the many ideas suggested at the Bradford meeting will ultimately take the strongest hold in the struggle for existence, as the fittest to survive. The *pièce de resistance* in the debate was, we consider, the

Digitized by Google

electron theory of matter—that matter is made up of one primordial atom, the atom of electricity, whose existence was first emphasised by HELMHOLTZ: the electron, as Dr. JOHNSTONE STONEY has very aptly styled it. We regret that the name of PROUT was not mentioned in the discussion, but this we suppose was a mere accident, although the theory is truly PROUT'S in modern dress. The evidence in support of this great generalisation is no doubt still scanty; but nevertheless the theory has received the support of experimental discovery. For example, it has been shown by FITZGERALD, LARMOR, and LORENZ that it affords the simplest explanation of the results of the experiments of MICHELSON, on the supposition that the diameter of the earth is slightly altered to the extent of 4cm. by its motion through the ether. One point, however, which appears to us to be of no little moment, and to give some support to the theory that all matter is made up of electrons, was omitted in the discussion, namely, the relation that has been found by LENARD to exist between Lenard rays—or, as we may now be justified in calling them, electrons—and the mass of bodies through which they pass. LENARD, it is well known, found that in every case the absorption is directly proportional to the density. This fact appears to add substantial weight to the theory that the atoms of matter are really made up of such electrons. These electrons, which have been found to compose cathode rays, Lenard rays, and one type of the radiation from radio-active substances, have been shown to move with a velocity so great as one-third of the velocity of light, and in so doing they are enabled to travel through considerable thicknesses of metals. What, we ask, would be the result if they actually moved with the velocity of light? Their effective inertia, we know from the electromagnetic theory, would be infinite. It is possible that in moving through a body like the Earth they may encounter some measurable resistance. If this be so, the dream of LE SAGE may, in part, have been realised; for a swarm of such particles or electrons from all directions in space, and moving with the velocity of light, or almost this velocity, towards a given centre, would, by the resistance offered to them, exert a pressure proportional to the mass of a body placed in their path, and to the solid angle subtended by that body at the centre, towards which they all tend. In other words, the pressure would be proportional to the mass of the body, and likewise to the mass of any body placed at the centre, and at the same time would vary inversely as the square of the distance between them. But, after all, vague speculations of this sort do not go far towards clearing up the problem of gravitation.

The discovery of Röntgen rays marked an epoch in the history of the science of matter in its ultimate state. The identical properties which they possess with cathode rays, Lenard rays, and the rays from radio-active bodies in every case—except one, that they are not deflected by a magnet—is in itself highly suggestive; and we may remind our readers that when LENARD attended the meeting of the British Association at Liverpool he strongly and stoutly maintained the identity of the rays he had discovered with those of RÖNTGEN. At present such questions are still in the region of debate and uncertainty. But each and all of them would seem to afford clues, some more clearly defined than others, pointing to the solution of the great problem of physics and chemistry—the ultimate constitution of matter. It will be only by persistently following up these clues, and strengthening each step by experimental evidence, that the proper value of the electron theory as a solution of this problem will be established.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. FOURNIER D'ALBE.]

Dielectric Strength.—The dielectric strength of a medium is measured by the fall of potential per unit of length along the lines of electric force which the medium will stand without breaking down and allowing a spark to pass. The minimum of dielectric strength lies at a pressure of about 0·7mm. in hydrogen, 0·3 in air, and about the same in carbonic acid. In hydrogen, the minimum strength is 233 volts per cm., in air 300, and in carbonic acid 378. The measurements are taken, according to E. Bouty, in a field between two plane and parallel electrodes. This gets rid of brush and glow discharges. When the variation of the dielectric strength with the pressure is studied, it is seen that, apart from the lowest pressures, the dielectric strength varies with the pressure in a lineal manner. If y is the dielectric strength and p the pressure, the relation between the two is expressed by the formulæ

$$y = 1{\cdot}4 + 63{\cdot}33\,p \text{ in hydrogen.}$$
$$y = 1{\cdot}593 + 119{\cdot}09\,p \text{ in air.}$$
$$y = 1{\cdot}703 + 144{\cdot}4\,p \text{ in carbonic acid.}$$

The constant term denotes no doubt the part played by the electrodes in opposing the passage of an electric discharge. The above values are those found for glass, whereas much higher ones were found by Max Wolf for brass. Wolf's direct relation between the coefficient of p and the inverse mean free path is correct as between hydrogen and air, but only very roughly so in the case of CO_2.

[E. BOUTY, *Comptes Rendus*, August 20 and 27, 1900.]

Metastability of Weston Cell.—E. Cohen has found an important flaw in the perfection of the cadmium cell as a standard of E.M.F. Not only can cadmium sulphate in the form used, *viz.*, $CdSO_4 + 8/3H_2O$ exist in two modifications below 15deg., but the cadmium amalgam itself is unstable, and can exist in two modifications below 23deg. The amalgam contains 14·8 per cent. of cadmium. At 0deg. a potential difference of 5 millivolts exists between the two modifications of the cadmium amalgam, and that difference is, of course, large enough to destroy the suitability of the cell as a standard of E.M.F. The fault is found both in the cells of the Reichsanstalt and of the European Weston Electrical Instrument Co. The passage from one modification to the other is apparently quite spontaneous. Above 23deg. there is, of course, no danger, but then a constant temperature cannot be ensured without the use of a thermostat, and the supposed advantages of the Weston cell, derived from its surprisingly low temperature coefficient, are thus rendered illusory. No doubt a similar instability exists in the Clark cell, and it is only by a careful study of the behaviour of the various cadmium amalgams and compounds that any improvement can be attained. Such a study is now being pursued in Amsterdam.

[E. COHEN, *Proc. Akad., Amsterdam*, August 28, 1900.]

Conductivity of Pressed Powders.—The distinction between metallic and electrolytic conduction is chiefly based upon the temperature coefficient of the resistance. If the resistance increases with the temperature, the conduction is metallic. If it decreases, the conduction is electrolytic. Conductors belonging to both classes, or to an intermediate class, have not hitherto been obtained. But F. Streintz has made some experiments on powdered conductors which indicate something like a transition from one class to the other. He prepared fine powders of platinum black, graphite, and lamp-black, and subjected them to considerable pressure in a hole bored in a block of ebonite, at the same time determining their resistance by auxiliary electrodes inserted in the block. The resistance of 1mm. of platinum black having a section 1mm. square was found to be 0·92 ohms at zero, as against 0·14 for ordinary metallic platinum. But the temperature coefficient of platinum black is only half that of platinum. Lampblack under the same conditions showed a resistance of 40,000 ohms, and a *negative* temperature coefficient amounting to the enormous value of 1 per cent. for 1°C. The column of lampblack is therefore equivalent to a dilute solution of

Digitized by Google

sulphuric acid. Graphite, on the other hand, showed a resistance of only 21·9 ohms, and had a positive temperature coefficient. It therefore ranges itself among the metals in this respect. To complete the electrolytic character of lampblack, some kind of ionisation and consequent polarisation remains to be established.

[F. STREINTZ, *Ann. der Physik*. No. 9, 1900.]

Magnetisation of Electrolytic Iron.—Electrolytic iron has hitherto been studied after its formation. C. Maurain has, however, conceived the idea of investigating its magnetic properties in the act of deposition, and depositing it under the influence of magnetic fields of various intensities. The deposits were obtained from a solution of ferrous sulphate in sodium pyrophosphate, and were very brilliant and adhesive. The brass electrodes were mounted in the centre of the magnetising coil itself. It was found that the magnetometer deflection, produced by the deposit, increased in a linear with the time. Since the current was steady, this means that the magnetic susceptibility of the bottom layers of the deposit remained the same as that of the top layer. The magnetisation also increased with the magnetising force, and in that respect the deposit showed no difference from a deposit magnetised after deposition. But a quantity not hitherto fully appreciated is the high coercive force and residual magnetism of these deposits. There is practically no loss of magnetisation after the removal of the field. It even resists an opposite field, when the latter is not too strong. But when the opposite field attains a certain strength, say 20 units, the collapse of the magnetisation is sudden and complete. Nickel similarly deposited, though showing the same remanent magnetism, exhibits a gradual diminution of magnetism with an increasing demagnetising force.

[C. MAURAIN, *Comptes Rendus*, August 13, 1900.]

Mechanical Action of Cathode Rays.—Experimental determinations of the force exerted by cathode rays upon light moveable bodies are as yet lacking, though Riecke has estimated the force acting upon a cathode shaped like a propeller. If the force thus found is regarded as that due to the reaction of projected particles, an amount of energy results which surpasses the whole energy of the cathode rays. It is, therefore, not permissible to deduce the kinetic energy of the cathode particles from such experiments. H. Starke has adopted a different arrangement. He used a cathode with a number of plates resembling a propeller. But the cathode was kept fixed, and the cathode rays impinged at an angle of 45deg. upon a thin plate of aluminium suspended above the cathode by means of a thin platinum wire. The results were almost all negative. An influence machine gave nothing but irregular disturbances, probably due to electrical forces unconnected with the impact of cathode rays. An influence machine of 20 plates, yielding a discharge potential of 10,000 volts, and a current intensity of 10^{-7} amperes, gave something like an appreciable deflection, which indicated, however, that the force to be measured is below 10^{-4} dynes. The experiments are to be continued.

[H. STARKE, *Ann. der Physik*, No. 9, 1900.]

Protection of Magnetic Observatories.—The new electric tramway between Vincennes and Nogent-sur-Marne, which passes at a distance of 3,000 yards from the Parc Saint Maur magnetic observatory, disturbs the needles at the latter to a very appreciable extent, the greatest disturbances being due to the electrical events attending the starting of the cars. Fortunately, these disturbances are symmetrical to the natural curve, and are of a much greater frequency than the natural fluctuations of the earth's magnetism. They can therefore be made practically negligible by employing needles of square or rectangular section, strongly magnetised, by increasing the moment of inertia of the swinging system by means of a piece of copper, and by damping with copper discs. This has been done by T. Moureaux with a declinometer and a bifilar magnetometer, for which bars 5cm. long and 5mm. thick were chosen, with a magnetic intensity of 200 units. The ordinary bifilar showed oscillations amounting to 0·0002 C.G.S. units, but these disappeared almost completely on the new bifilar. A bifilar put up in the Fort de Nogent, within 800 yards of the tramway, showed disturbances of 0·0003 units, which were, however, reduced to one-tenth of that amount in the new instrument. The only effect of the vagrant currents was a slight thickening of the curve traced by the magnetograph.

[T. MOUREAUX, *Comptes Rendus*, July 30, 1900.]

THE INTERNATIONAL ELECTRICITY CONGRESS.

The International Electricity Congress, which was held in Paris in connection with the 1900 Exhibition from Aug. 18 to Aug. 25, was formally opened by M. Mougeot, Under-Secretary of State for Posts and Telegraphs, on Saturday, Aug. 18. France was represented by delegates from the Ministries of Commerce, War, Marine, and Agriculture; other countries which had sent delegates were Great Britain, Germany, Austria, Belgium, Bulgaria, Corea, Denmark, Ecuador, Spain, United States, Guatemala, Hungary, India, Italy, Japan, Liberia, Luxembourg, Mexico, Norway, Holland, Russia, Servia, and Switzerland. The following societies were also represented:—

Association Amicale des Anciens Élèves de l'Ecole de Physique et de Chimie Industrielle de la Ville de Paris.
Association Amicale des Ingénieurs Electriciens.
Association des Industriels du Nord de la France.
French Chamber of Commerce.
Compagnie des Chemins de fer de l'Ouest.
Société Amicale des Ingénieurs sortis de l'Ecole Supérieure d'Electricité
Société Française de Physique.
Société Internationale des Électriciens.
Syndicat Professionel des Industries Electrique.
Syndicat Professionel des Usines d'Electricité.
Elektrotechnische Institut of Karlsruhe.
Verband Deutscher Elektrotechniker of Berlin.
Elektrotechnischer Verein of Vienna.
Association Amicale des Ingénieurs Electriciens sortis de l'Institut Electrotechnique Montefiore de Liège.
Canadian Electrical Association of Toronto.
American Institute of Electrical Engineers.
Franklin Institute (U.S.A.).
New York Electrical Society.
Institution of Electrical Engineers (Great Britain).
Koninglijk Institut van Ingenieurs de La Haye.
Société des Ingénieurs et Architectes Hongrois of Budapest.
Associazione Elettrotecnica Italiana of Turin.
Societa d'incoraggiamento d'Arti e Mestieri of Milan.
Associacão des Engenheiros civis Portuguezes.
Association Suisse des Électriciens.
Parnasse d'Athènes.

The number of members of different nationalities attending the Congress was as follows:—

France	346	Canada	4
Germany	79	Argentina	4
Belgium	54	Brazil	3
Great Britain	51	Turkey	3
United States	50	New Zealand	2
Italy	45	Chili	1
Switzerland	39	Denmark	1
Russia	20	Egypt	1
Austria	16	Luxembourg	1
Hungary	10	Peru	1
Holland	10	Portugal	1
Spain	5	Sweden	1
Japan	5		
Roumania	5	Total	758

In his words of welcome, M. Mougeot alluded particularly to the foreigners who had hastened to Paris in a common sentiment of fellowship and love of science, all with the same idea of solidarity and anxious to improve the lot of humanity. After M. Mougeot's graceful words of welcome, M. Mascart, President of the Organisation Commission of the Congress, delivered a short address, also expressing his gratitude to the number of his foreign colleagues who had replied to the Committee's invitation to attend the congress. He expressed the hope that this reunion of savants and engineers of different countries, who had directed their efforts to the progress of electricity, would tend to strengthen the bonds of friendship formed previously at similar gatherings and to create fresh friendly relations. M. Mascart then gave a short historical sketch dealing with the development of electricity during the past century, and pointed out the entire

Digitized by Google

transformation it had brought about in all industrial and commercial methods. The following general committee was then elected :—

PRESIDENT : M. E. Mascart.

VICE-PRESIDENTS :

France.—MM. Moissan, H. Fontaine and Gariel (Vice-preaidents of the Organisation Commission).
Germany.—Prof. F. Kohlrausch and Prof. Dorn (delegates of the German Empire).
England.—Prof. Perry and Sir William Preece (delegates of the British Government).
Austria.—Prof. Jullig (delegate of the Austrian Government).
Belgium.—M. Eric Gérard.
United States.—Mr. Carl Hering and Dr. A. E. Kennelly (delegates of the United States Government).
Hungary.—M. de Fodor.
Italy.—Prof. Colombo (delegate of the Italian Government).
Russia.—Prof. de Chatelain (delegate of the Russian Government).
Switzerland.—M. Turrettini (delegate from the town of Geneva).

GENERAL SECRETARY : M. P. Janet.

REPORTER : M. Hospitalier.

Presidents were then chosen for the various sections :—

Section I.—Scientific Methods and Measuring Apparatus.—M. Violle.
Section II.—Sub-section A : Production and Mechanical Utilisation of Electricity.—M. H. Hillairet. Sub-section B : Electric Lighting.—M. Hippolyte Fontaine.
Section III.—Electro-Chemistry.—M. Moisson.
Section IV.—Telegraphy and Telephony.—M. Wünschendorff.
Section V.—Electro-Physiology.—M. d'Arsonval.

The President read a letter from Lord Kelvin, who expressed his regret at being unable to attend the congress, owing to ill-health, and wished the congress every success. A telegram of thanks and respectful sympathy was addressed to Lord Kelvin in reply.

Profs. Ayrton and Dorn then expressed the thanks of the foreign delegates for the graceful and hearty welcome which had been extended to them.

On Monday, Aug. 20, and during the week the various sections met separately.

Section I.—*Scientific Methods and Measuring Apparatus.*

On Monday M. Cornu explained a new system of units proposed by M. Rey-Pailhade, based on a physical unit of time equal to the 100,000th part of the mean solar day. The examination of the whole question of units was, however, relegated to a committee formed as follows :—

Prof. Ayrton (Great Britain), Prof. de Chatelain (Russia), Prof. Dorn (Germany), M. de Fodor (Hungary), M. Gérard (Belgium), M. de Hoor Tempis (Hungary), M. Hospitalier (France), M. Lombardi (Italy), and Dr. Kennelly (United States).

A short discussion on "Photometry" followed, in which MM. Cornu, Gova, and Hospitalier took part.

On Tuesday, August 21, Mr. Hildburgh gave a detailed description of apparatus for rectifying alternating currents, and this was followed by a Paper by M. Arnoux on practical standards of E.M.F.s. M. Arnoux referred to the Clark standard cell adopted by the 1893 congress at Chicago, and pointed out the defect of a large temperature coefficient, which was not always known with accuracy, and also the large variation in the internal resistance of the cell, which necessitated the employment with it of highly-sensitive and not very portable galvanometers. In 1884 Czapski called attention to the cadmium cell, in which cadmium and sulphate of cadmium replaces the zinc and sulphate of zinc in the Clark cell, with the result that the variation of E.M.F. with temperature is about a thirtieth as great. Later, in 1897, Jaeger and Wachsmuth made an interesting study of the cadmium cell at the Berlin Reichsanstalt, confirming the observations of Czapski. Gouy, to whom a bioxide of mercury cell is due, had made an interesting and very complete communication to the 1900 International Physics Congress on the cadmium standard, in which he acknowledges that his own cell could not rival the cadmium cell with regard to temperature variation. Gouy made use of the H form of cell adopted by Jaeger, Wachsmuth, and Kahle, but M. Arnoux himself prefers the ordinary cylindrical arrangement in practice, as it enables cells to be made of about a fiftieth the resistance, and with which, in consequence, less sensitive and more portable galvanometers can be employed. M. Weyde having exhibited a mechanical model representing the effects of a continuous or alternating E.M.F. in a circuit possessing resistance, self-induction, and capacity, the section adjourned for the day.

The first part of the session on Wednesday was devoted to oscillographs. M. Blondin exhibited, on behalf of M. Blondel, some new oscillographs, devised by the latter and constructed by M. Dobkevitch. There were three types of this apparatus, viz., the bifilar one, one with soft iron, and the third with a strip of soft iron, a modification of the last mentioned. After explaining the details of the three instruments, and showing the optical arrangement permitting the curve to be projected either on a photographic plate or on a screen, M. Blondin considered the relative advantages and disadvantages of the various types. The bifilar oscillograph was the most accurate, but it required delicate handling and was particularly suitable for laboratory investigation. The frequency of the oscillations of the moving part was 10,000 to 15,000 oscillations per second. The oscillograph with the soft iron strip was recommended for commercial use. Its frequency of oscillation could reach 45,000, and, constructed with a permanent magnet, its weight did not exceed 12kg. to 15kg. A single incandescent lamp sufficed to photograph the curves, and, owing to the use of a permanent controlling magnet, continuous current was not necessary when using it. Mr. Duddell referred to the work he had done in connection with these instruments, and stated that, so far as the bifilar oscillograph was concerned, he had come to the same conclusion as M. Blondel, with whose researches he had not been previously acquainted. M. Dobkevitch gave the following figures for the oscillograph : With a vibrating ribbon without magnetic shunt, 25,000 to 80,000 vibrations, with a sensibility of 40mm. per ampere at a scale placed at a metre distance ; with a strong magnetic shunt, about 10,000 vibrations with a sensibility of 180mm. per ampere at a scale placed at a metre distance. By varying the magnetic shunt he could obtain various degrees of sensibilities and frequencies. The dimensions of the mirrors were : Thickness, between 0·06mm. and 0·10mm. ; width, 0·2mm. to 0·3mm. ; height, 0·5mm. to 1mm. M. Carpentier also spoke, alluding to M. Abraham's method of recording variable currents.

A Paper was then read by Mr. Addenbrooke describing a set of electrostatic instruments for performing accurate measurements on alternating-current circuits. The instruments are intended to perform for alternating currents more or less what the Crompton potentiometer does for continuous currents. The ammeter is an electrostatic voltmeter connected to the terminals of a resistance in the main circuit, and the wattmeter is an electrometer whose quadrants are connected to these same terminals while the needle is connected to one terminal of the alternator or is given a potential proportional to it.

The proceedings on Thursday were opened with a Paper by M. Violle on "Photometry." M. Violle first quoted the conclusions of the International Congress at Geneva in 1896 with regard to photometric units and standards of light, and then proceeded to criticise these and to review the various investigations of light standards which have been made since then. He concluded his Paper with a description of some recent photometers. Herr Hartmann, of the well-known Frankfort firm of instrument makers, then presented a note on "Apparatus for Measuring the Frequency of Alternating Currents." This apparatus consists, in principle, of an electro-magnet traversed by the alternating current, which acts on a vibrating strip and makes it emit a sound. The electro-magnet is placed successively in front of a series of these strips, and the one that give the sharpest sound is discovered. Up to a certain point the excitation of the neighbouring strips permits the apparatus to be used for certain frequencies not included in the natural periods of vibration of the strips in the series. Herr Hartmann then exhibited an apparatus based on the same principle and intended to control the frequency of a given alternating current. It consists of two vibrating strips adjusted to frequencies, one slightly greater and one slightly

Digitized by Google

less, than the frequency required. When the frequency is constant the apparatus will emit no sound at all. M. Blondin then presented on behalf of M. Blondel a communication on tests of two-phase or three-phase alternators made at the Central Laboratory of Electricity by MM. Blondel, Dobkevitch, Duris, Farmer, and Tchernosvitoff by means of oscillographs. They found that the load on one phase caused a deformation of the wave form of the other phases, this deformation being greater the more unequal the loads were. Finally, the armature reaction produced in the field-magnet circuit pulsations which were often very strong, and whose frequency was double the product of the frequency of the armature current and the number of phases.

On Friday the Units Committee presented their report, which was as follows:—

The Committee does not take into consideration propositions to introduce any modification into the decisions of previous congresses.

The Committee does not consider it necessary at present to give names to all the electromagnetic units. However, in view of the employment of practical measuring apparatus giving directly field strength in C.G.S. units, the Committee recommends that the name "Gauss" be given to the C.G.S. unit.

The Committee also proposes to call the unit of magnetic flux, whose magnitude shall be defined subsequently, the name "Maxwell."

Dr. Kennelly, in the name of the American Institute of Electrical Engineers, withdrew its propositions with regard to the prefixes and rationalisation of electromagnetic units.

The first clause of the report was passed unanimously, but there was some discussion on the other recommendations. M. Mascart did not consider that it was necessary to give any name to the C.G.S. unit of magnetic field. He was of opinion that this decision was contrary to the spirit of the congresses of 1881 and 1889, which did not give to the C.G.S. units the names of savants. He would admit that a name might be given to a practical unit. In any case, however, the name of Gauss seemed likely to lead to confusion, for Gauss was the inventor of the first absolute system (millimetre-milligramme-second), which was still employed at the present day in certain cases. M. G. J. Van de Well was in favour of adopting the name Maxwell for the unit of magnetic flux, but he thought that the magnitude of this unit should be defined. Prof. Kohlrausch said that the absolute units sufficed for physicists, but if engineers found the necessity of naming the units, Prof. Dorn and himself did not see any inconvenience in their giving them names such as Gauss and Maxwell for instance. However, the German delegates could not, he said, give an undertaking on behalf of their Government, and he thought that the congress should limit itself to recommending these new names without trying to give them a legal sanction. Prof. Ayrton was of the same opinion as M. Mascart, and pointed out that apparatus such as the Ayrton-Mather field tester had been used for several years without any necessity being felt for giving a name to the unit of field strength. Moreover, the C.G.S. unit of magnetic field was the one in practical use. M. Mascart said that there was ambiguity in the word "practical." Although the C.G.S. unit of magnetic field was employed in practice, it did not belong to what was called the practical system of units. M. Hospitalier desired that they should give names to the two units in question. He did not ask for a legal decision, but a simple recommendation by the section. After further discussion, in which MM. Ayrton, Carpentier, Dorn, Fernandez, Adison, Hospitalier, Kohlrausch, Mailloux, Mascart, Alexander Siemens, and Silvanus P. Thompson took part, at the suggestion of M. Eric Gérard the question was put by the President whether the section would recommend that special names be given to the C.G.S. units of magnetic field and magnetic flux, and this proposal was adopted with only two dissentients. After a short adjournment the two proposals were put that the section recommended the adoption of the name "Gauss" for the C.G.S. unit of magnetic field and the name "Maxwell" for the C.G.S. unit of magnetic flux. These two recommendations were adopted successively, two members only dissenting in each case.

M. R. Arnoux then exhibited a new type of thermo-galvanometer which he had designed in conjunction with M. Chauvin. This instrument differed from others on the same principle in the arrangement of the gear to amplify the deflection, and in the arrangement to compensate for the external temperature. The hot wire of variable length f is coupled to a fixed lever of very short length, b, and these two form a triangle with the frame of the instrument, the length of the third side being a. The angle F of this triangle subtending the hot wire will be very nearly 180deg. The following relationship is obtained between these magnitudes: $f^2 = a^2b^2 - 2ab \cos F$. On differentiating, this becomes

$$f df = ab \sin F dF, \quad \text{or} \quad \frac{df}{dF} = \frac{f}{ab \sin F}.$$

This relation shows that a small variation in the angle F, corresponding to an elongation df of the wire will have a maximum value when the lever b is very small and the angle F either very nearly zero or very nearly 180deg. By employing this principle, a deflection of 90deg. of the needle was obtained with the consumption of 0·85 watt in the hot wire, corresponding to a current of 3·5 amperes at one-tenth of a volt, whereas most hot wire instruments would require three-tenths of a volt with the same current for this result. The arrangement for compensating for variations of external temperature consists of fixing parallel to the hot wires a number of wires identical to it and stretching the whole by means of a strong steel spring.

M. P. Janet described a recording apparatus made for him by M. Richard. This apparatus had been specially designed to study the working of three arc lamps connected in series. It included three recording voltmeters to register the differences of the potential at the terminals of each of the lamps, and a recording ammeter for the current. The four pens register on the same drum, which facilitates the comparison of the curves.

At the afternoon sitting on Friday, M. C. Perskyi read a communication on "Television," describing a number of apparatus based on the magnetic properties of selenium.

(*To be continued.*)

THE CENTRAL LONDON RAILWAY.

(*Continued from page 732.*)

At each sub-station the secondaries of the six transformers are brought by means of low-pressure switches (Fig. 46) to three main 'bus bars, which lead to the top terminals of each of the two 2,000-ampere Samuelson quick-break switches seen upon the two panels immediately to the left of the transformer panels (Fig. 45). These two panels are devoted to the alternating-current side of the two 900kw. rotary converters. These switches carry 2,000 amperes per blade at 330 volts, and have to be protected by marble division slabs. From their bottom terminals leads are carried down under the floor to the brush holders for the collector rings of the rotary converters. A diagram of the switchboard connections is shown in Fig. 47.

The rotary converters are 12-pole, three-phase, 25-cycle machines, corresponding to a speed of 250 revs. per min. Each has an output of 900kw. at 500 volts continuous current, the alternating-current input voltage corresponding to this being 305 across collector rings. Fig. 48 shows an elevation and section of one machine. The base, a cored iron casting, is in one piece, and on this are bolted the bearing pillow blocks, the magnet frame, and collector brush rigging brackets. The magnet frame or yoke is of mild cast steel, in two halves bolted together, and carries the 12 inwardly-projecting magnet cores and pole-pieces, which are of laminated sheet steel. The field coils are wound on sheet-iron spools having brass flanges. The winding space on each spool is divided, the upper portion being devoted to the shunt winding, which consists of 912 turns in series of No. 11 B and S per spool, while the lower portion is reserved for the series winding. This series winding consists of eight copper strips, 2·5in. by 0·075in., in parallel, there being 2½ turns per spool. The object of this compounding is that the rotary may be adjusted automatically to maintain constant voltage under all conditions of load by means of phase control. Nominally, a rotary converter has a fixed ratio of voltage

Digitized by Google

between collector and commutator, but the voltage between the generator and rotary collector ring may be varied by displacing the phases of current and E.M.F., causing the current to lead or lag, as higher or lower voltage of commutator may be required. This is only the case if reactance arrangements be introduced, but in practice, unless extreme variations are required, sufficient reactance exists in the armature of the generator itself, and the leading currents in its armature, produced by the over-excited rotary, help the field excitation, and considerable variation of voltage may be obtained. Thus, suppose in this case a heavy load comes on, the field becomes over excited, by reason of the increased ampere turns due to the series winding, and causes the alternating currents to lead in phase, with a corresponding higher voltage at the commutator. The compounding has been so adjusted, by shunting part of the series amperes, that the continuous-current voltage keeps quite constant even under the most trying fluctuations of load. The outside diameter of the magnet yoke is 123in.; the length parallel to the shaft is 22in., and the magnetic density in the steel 48,000 lines per square inch. The magnet cores are 12in. square, and the length of the pole arc 15⅞in.; the density in cores is 95,000 lines per square inch. The armature core, which is slotted to receive the winding, is built up of separately insulated sheet-

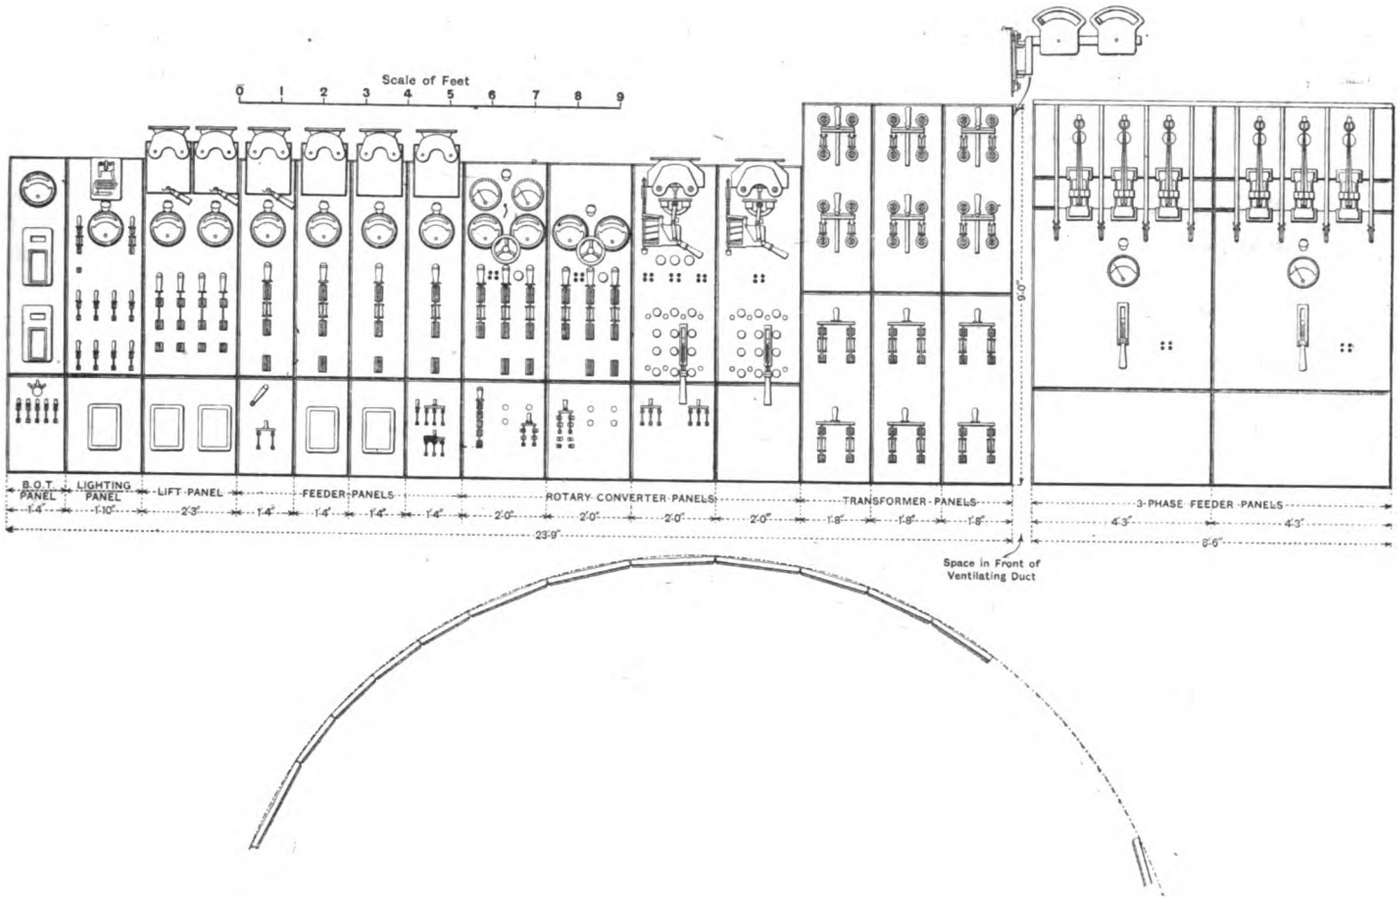

FIG. 45.—GENERAL ARRANGEMENT OF HIGH AND LOW-PRESSURE SWITCHBOARD AT THE NOTTING HILL GATE SUB-STATION.

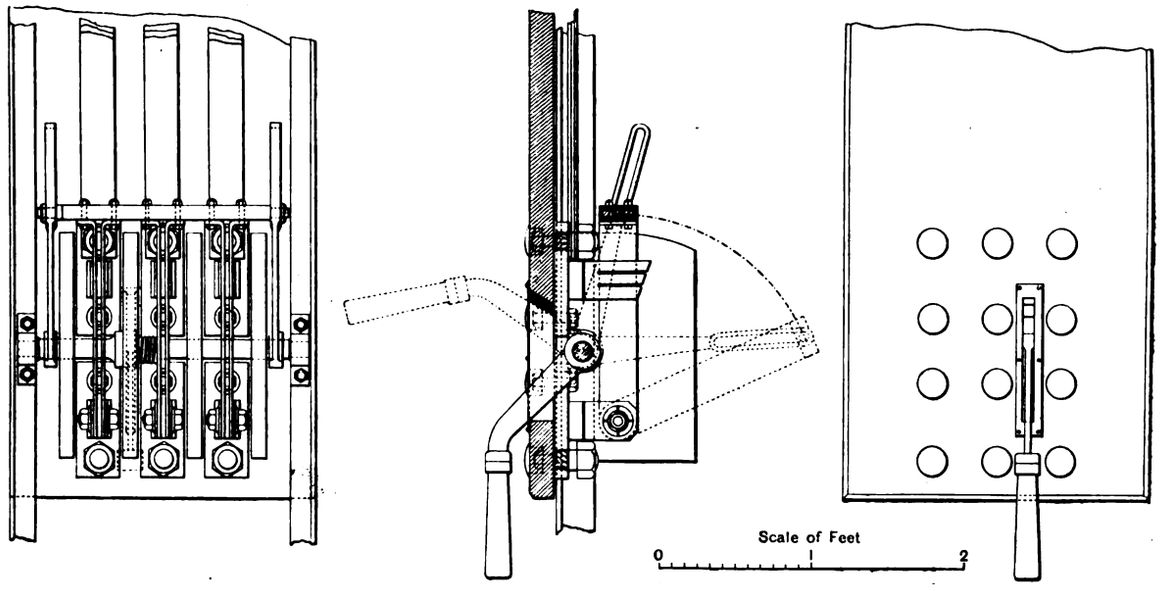

FIG. 46.—THREE-PHASE LOW-PRESSURE SWITCH.

Digitized by Google

iron punchings 0·014in. thick, and is carried on a heavy cast-iron spider, the laminæ being secured thereto by dovetailing. The magnetic density in the teeth is 128,000 lines per square inch, and in the core below teeth 51,000 lines. The winding is of the multiple circuit drum class, bar type construction being employed. There are four

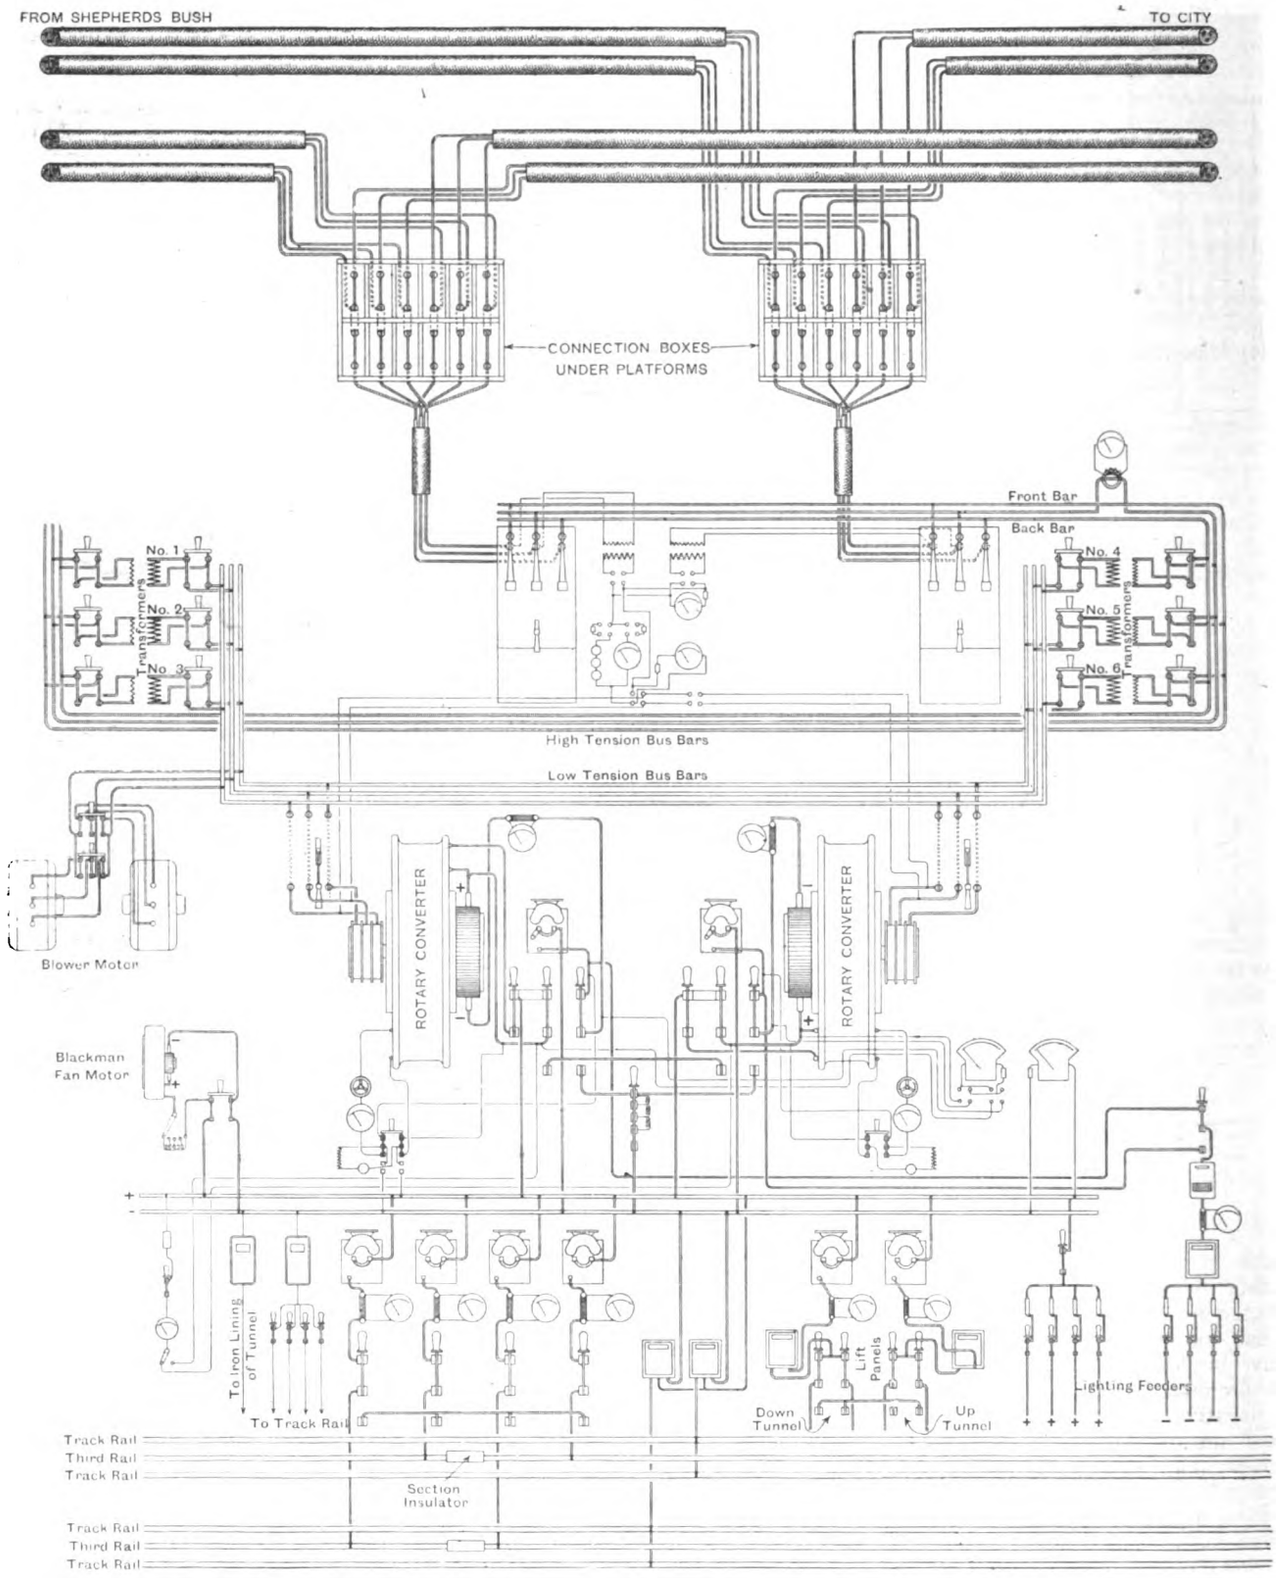

FIG. 47.—DIAGRAM OF CONNECTIONS AT THE NOTTING HILL GATE SUB-STATION.

conductors, each 0·4in. by 0·125in. per slot, the dimensions of the slots being 1·25in. deep by 0·44in. wide, and 288 such slots altogether. The number of parallel paths through the armature is 12, leaving 48 turns in series between brushes. The cross-section of these 12 paths is 0·6 sq. in., and figuring on the resultant current gives a current density of 2,400 amperes per square inch. Into this winding are 18 equidistant tappings for the three-phase currents, or three tappings per pair of poles, which are brought down to the three collector rings carried on a separate spider on the shaft. The collector is 24in. diameter, and each ring is 3½in. wide, and has eight copper gauze brushes, which are supported on cast-iron brackets bolted to the base. The commutator is 54in. diameter and 17½in. long, and has 576 segments, or one segment per turn. It is supported by a separate cast-iron spider. There are 12 sets of carbon brushes, each set having

Digitized by Google

eight brushes 1½in. wide by ¾in. thick, and they are carried in holders on spindles fixed to brackets on a cast-iron ring. This ring is supported on arms bolted to the magnet frame, and is free to move in a groove turned in these arms. By means of a handwheel and worm this ring, carrying all the sets of brushes, can be rocked round to any position, but in actual operation for all loads the brushes remain fixed at the mechanical neutral position.

The weights of the various parts of the machines are approximately as follows:—

Armature, complete with collector, commutator and shaft	24,800lb.
Magnet frame, cores, pole pieces, and spools complete	19,550lb.
Collector brackets, brush rigging, &c.	4,000lb.

Returning to the switchboard (Figs. 45 and 47) we find the next two panels contain the main switches and instruments for the continuous-current side of the rotaries, one panel being for each rotary. The three large single-pole, quick-break, divided blade switches on each panel are the positive, equaliser and negative switches respectively. The bottom of the positive switch is connected to the series winding and the top is connected to the positive 'bus bar. The latter two switches are double throw, the lower point connects the equaliser switch to the equaliser 'bus bar, and the upper position connects positive brush ring direct to the positive 'bus bar, the rotary then running as a shunt machine. If the positive is closed at the same time then the series winding is short circuited, but if open then the series winding is open. The negative switch when thrown upwards—which is its normal running position—connects the machine through the circuit-breaker to the negative 'bus bar. The circuit-breaker is located above the three-phase rotary switch for that particular machine. The down position connects the machine through the starting rheostat to the negative 'bus bar. Above the negative switch is the main ammeter, of the Weston shunt type, showing the total current going out from the rotary on the continuous-current side. The field switches, which are of the double-pole type, are mounted on the sub-bases of their respective panels, and the field ammeter, which reads either way, is mounted to the left of the main ammeter in each case. The field rheostat is mounted above the board, and is regulated by means of a hand wheel. Auxiliary three-pole field switches are mounted on the sub-bases of the three-phase rotary panels, so that when starting up on the alternating-current side the field can be divided into four separately-insulated parts, the double-pole field switch also being open. On the sub-base of No. 1 rotary panel there is the four-point starting rheostat, one end of which is connected to the bottom terminals of the two negative switches and the other end to the negative 'bus-bar. Also at the top of this panel there is the alternating current machine voltmeter, which can be connected across two of the rings on either rotary by means of a plug receptacle on each panel. To the right of the machine voltmeter is the synchronising voltmeter. The synchronising lamps are located, besides the circuit breaker, on No. 1 three-phase rotary panel.

Now follow the four-line feeder panels. The positive 'bus bar is continued along the top of these panels, and feed down to each feeder through separate circuit-breakers and double-throw quick-break switches. The third rail is divided in each tunnel at a point outside each sub-station. This enables the station to feed into any or all of the four sections by throwing the feeder switches to the "Up" position. By throwing the switches downward either or both rails may be made electrically continuous by means of a common 'bus bar connecting the lower points of the switches together; and the line can be fed right through by the other stations at work at the time, thus enabling the station to shut down. A Weston shunt type ammeter connected in each feeder indicates the current going out to each section. The track rails are in permanent connection to the negative 'bus bars. The total current returning by the rails in each tunnel is recorded separately by two Thomson integrating wattmeters (one for each tunnel). Mounted on the base of the first of the feeder panels are the two three pole switches for operating the two 6 H.P. three-phase blower motors for the air blast transformers. On the base of the fourth feeder panel is a double-pole switch and starting rheostat for a series-wound Blackman fan motor for ventilating the sub-station.

The passenger lift panel is arranged next to the feeder panels. There are two positive cables (one in each tunnel) running the entire length of the line. The lift motors at the various stations are connected to these and in each case use the rail as a return. The cables are brought into each sub-station and connected up to the middle points of the four lever

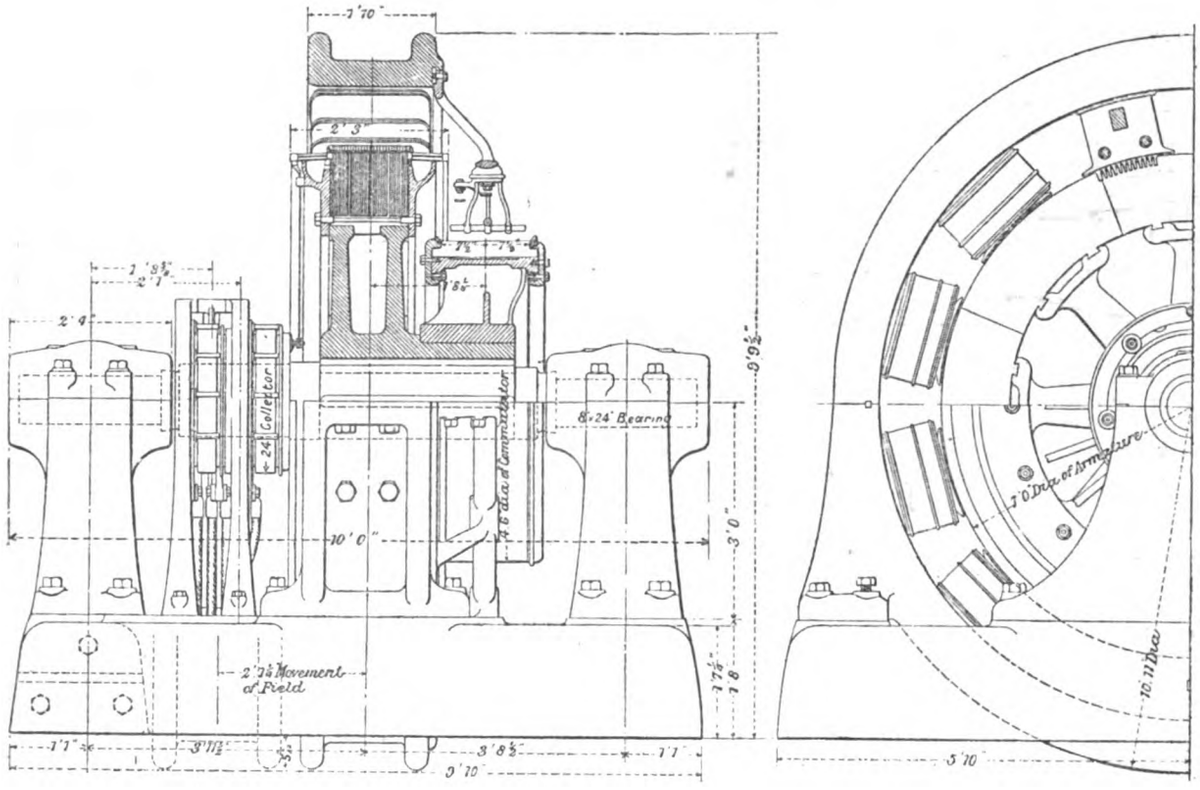

FIG. 48.—ELEVATIONS AND PART SECTION OF THREE-PHASE CONVERTER.

Digitized by Google

switches, two for either direction. The bottom point connects all cables together, and serves to interconnect the separate sections of third rail, so that they may be operated independently of any particular sub-station. The top points of the four switches feed the four insulated sections of the third rail, two for each tunnel, each through an ammeter and circuit breaker to the positive 'bus bar at the back. Two Thomson integrating wattmeters are mounted on the sub-base of the lift panel, and record the total amount of current going out in either direction to the lifts. It is interesting to note that the ammeter reads either side of zero. The deflection to the left of zero corresponds to the amount of current restored to the line by the lift motors while their individual lifts are on their downward journeys. The lift cables might also act as auxiliary feeders to the line, but are not required for this purpose.

The main lighting and distributing switches are arranged on the next panel. Two positive and two negative lighting feeders run the whole length of the tunnel (one positive and negative in each tunnel). The distributing boards in each station are connected across these and the whole line is lighted up on the three-wire system. The positive and negative main cables enter each sub-station and are connected through switches and fuses to the positive and negative 'bus-bars. There are also several battery stations along the line which are also connected across the lighting mains, so that while the sub-stations are running the lighting can be done from the machines and also charge the batteries at the same time. A minimum cutout is in circuit, and is shown at the top of the lighting panel, so that should the machine volts drop below the battery volts the minimum cutout acts and throws the lighting load on to the batteries, thus preventing the batteries feeding back into the machine. The batteries are used for lighting the stations, offices, and depôt during the time that the line is shut down. There two main switches on the lighting panel, one a single-throw switch, which connects the positive lighting 'bus bars to the main 'bus bar, the other connects the negative lighting 'bus bars to the negative of either rotary (whichever may be running). A main ammeter indicates the total amount of current sent out for lighting. A Thomson integrating wattmeter records the total amount of energy used for lighting purposes.

The next and last panel on the board contains various testing instruments. The Weston round ammeter at the top of the panel is for testing the third rail leakage on any section from either rotary by means of a two-way switch on the sub-base of the panel. Underneath the ammeter is an Elliott recording voltmeter showing drop in volts from certain fixed points along the line to the sub-station. There is also a recording ammeter showing total return by earth to the sub-station.

(To be continued.)

Electrical Engineering in Bengal.—We have received a copy of six lectures on "Electrical Engineering with Particular Reference to the Conditions in Bengal," delivered last March by Mr. J. W. Meares at the Civil Engineering College, Sibpur. Mr. Meares, who is electrical engineer to the Government of Bengal, chose to treat his subject in an elementary manner, and his lectures are likely to have given a good general idea of electrical engineering methods to an audience of civil engineers who had not much previous knowledge of the subject of electricity. The lecturer devoted most attention to electric lighting, although possibly telegraphy might have been more useful to some of the civil engineering students. The three lectures on house-wiring and private generating stations, as well as model specification, extracts from wiring rules, and an electric lighting act, show that Indian and home practice do not differ very much. The wood-casing system is still preferred by Mr. Meares to more modern methods, with which he confesses that he has not had experience. There are as yet few public supply stations in India, and from the brief descriptions in the book it would appear that these are also erected more or less in accordance with European practice. Probably the buildings are different, but such detail was, of course, outside the scope of these lectures.

ELECTRICITY WORKS ACCOUNTS.

Halifax Municipal Electric Supply Works.

Since the acquisition of the tramways as a customer, the Halifax undertaking stands as a splendid example of the economy resulting from a combined lighting and traction load. The accounts which we deal with in our table indicate most excellent results all round.

A general and substantial reduction in the costs has been effected, and the result has been that in conjunction with the much greater output the working profit was £9,002, representing no less than 11 per cent. on the mean capital expended, and this notwithstanding the lower average total revenue secured of only 2·8d. per unit sold. The aggregate costs at 1·2d. per unit are just about half the average of stations of similar output in 1898. Of the total output of 1,371,333 units sold the tramways took 895,024 units, or 65·3 per cent., and of the total revenue for current sold (for all purposes) of £15,820 the tramways contributed £7,459, or 47·2 per cent. The beneficent influence of the traction load on the undertaking by increasing the load factor is not, of course, by any means adequately represented by the consequent low working expenditure. It is only by taking into account the influence on the capital charges that the advantages can be appreciated.

Of the working profit of £9,002, £810 represented the contribution to the sinking fund and £2,685 the interest charges. After meeting these and placing aside £3,489 to a renewal account there was left £2,000 transferable in aid of the rates.

A comparison of the results with those of past years is facilitated by the following table:—

Year to March.	Plant capacity kw.	Equiv. lamp con.	Output. Units sold.	Sold to tramways.	Sold for public lighting.	Total costs per unit sold.	Total works costs per unit.	Total rev. per unit.	Working profit to mean cap.
1896	600	9,816	119,028	—	4,815	4·74d.	3·36d.	5·74d.	1·27%
1897	600	14,146	177,530	—	12,430	3·57d.	2·55d.	5·86d.	3·78%
1898	850	20,800	239,814	—	21,107	2·87d.	2·05d.	4·85d.	3·77%
1899	1,400	32,020	628,759	279,867	59,264	1·65d.	1·21d.	3·42d.	7·11%
1900	1,250	45,403	1,371,333	895,024	82,123	1·24d.	0·90d.	2·81d.	11·0%

Nottingham Municipal Electric Supply Works.

Seldom have we to deal with accounts which indicate such sustained and rapid progress of an undertaking as do those of Nottingham. Last year we had occasion to note the result of the reduction in the tariff which was then made—viz., an advance in the lamp connections of nearly 77 per cent, and in the output of over 86 per cent. During the latter period covered by our analysis this week the lamp connections advanced from the equivalent of 67,339 to 100,378 8 c.p. lamps or by 49 per cent., while the output shows an increase of 66·7 per cent.

In character, as well as in magnitude the load has improved as is indicated by the load factor of 10·8 per cent., which obtained last year as compared with one of 9·3 per cent. in 1898-9.

Owing to the probably unavoidable rise in the fuel charge and in spite of a very general reduction in the other items, the works and total costs have slightly risen. In particular and in the aggregate, however, the various items of expenditure are all still well below the average at the output and load factor.

It will be noticed that the average revenue per unit has further dropped, exhibiting the very moderate figures of 2·8d. for ordinary consumers, and 2·96d. from all sources.

In the following table some figures are given which will show the progress the undertaking has made since the starting of operations:—

Year to March.	Lamp connections.	Output. Units sold.	Load factor per cent.	Total costs per unit sold.	Total works costs per unit.	Total revenue per unit.	Working profit per cent. to mean cap.
1896...	17,400	171,654	6·98	2·85d.	1·71d.	6·09d.	4·30
1897...	25,725	297,185	8·48	2·20d.	1·32d.	5·94d.	7·62
1898...	38,140	480,381	7·44	1·83d.	1·21d.	5·37d.	9·85
1899...	67,359	894,674	9·30	1·38d.	0·95d.	3·47d.	7·65
1900...	100,378	1,491,184	10·8	1·41d.	1·06d.	2·96d.	6·59

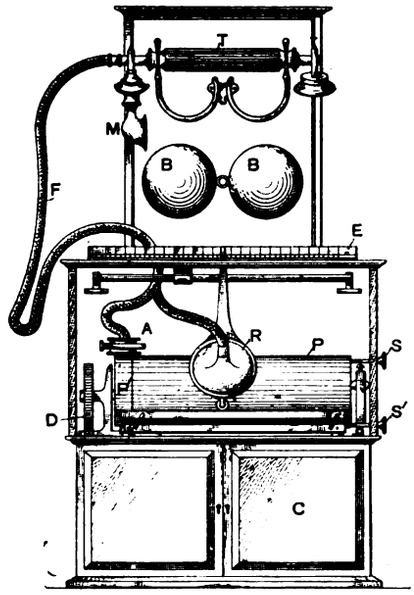
THE KUMBERG "TELEPHONOGRAPH."

In a recent issue (July 13, p. 427) we described a recording telephone, still in an experimental stage, which we had had an opportunity of examining and testing. The results did not appear to us particularly encouraging at the time, but since then Mr. Kumberg has been endeavouring to improve his instrument with a view to placing it on the market. We have received the following description from the inventor; it supplements to a certain extent our previous description:

This novel instrument is a combination of the phonograph with the telephone, and the accompanying drawing shows how it is achieved. The crux of the invention consists in a simple mechanical device, inside the electro-magnetic recording diaphragm cell R, which device increases and multiplies the impulses of the electrical vibrations, and thereby cuts clean and deep sound waves in the coating of a cardboard cylinder P, measuring 10in. in length, and 5in. diameter. This cylinder is interchangeable. By revolving the cylinder the record is made at 150 spirals to the inch, and the number of words which may be thus taken down when the whole length of cylinder is covered, is some 15,000, which would represent a page of an ordinary newspaper.

There is also a second cylinder P′ an inch broad, but of same diameter as its fellow P. The function of this cylinder is to take the place of an attendant and to answer calls. This is accomplished through the medium of the "automatic speaker" A, which informs the caller that Mr. Brown is out, and adds, for instance: "I am the telephonograph, if you will give your message it will be recorded, and Mr. Brown will hear it on his return."



When, on the other hand, the person who is called up is at hand, he disengages the automatic speaker A by means of the lever S′, and if he chooses to take his message without recording it phonographically, he can do so by pulling the upper lever S. M is a special mouthpiece having a separate channel for conveying the sound-waves directly to the recording stylus of the home station.

On the scale bar E slides a pointer which must be pushed against the tail of the electro-magnetic diaphragm R when leaving the office. The machine is then ready to record messages received. C is the battery and motor case. The other details of the sketch are common with ordinary telephonic instruments, and therefore no explanation if needed. In conclusion, it may be observed that the cylinders are inexpensive, and that the machine will soon be on the market.

Tramcar Fuse Boxes.—Several curious accidents, says the *Electrical Review* of New York, have taken place recently in New York and Brooklyn on account of dusty fuse boxes under street railway cars. Under some stress of overload, a fuse has suddenly blown, setting fire to the bottom of the car and causing "entirely unnecessary" panic among the passengers, who are alarmed by sudden outbursts of flames. It appears that, frequently, carelessness in caring for and inspecting fuse boxes has been the cause of this happening.

CORRESPONDENCE.

COHERER THEORY AND PRACTICE.

TO THE EDITOR OF THE ELECTRICIAN.

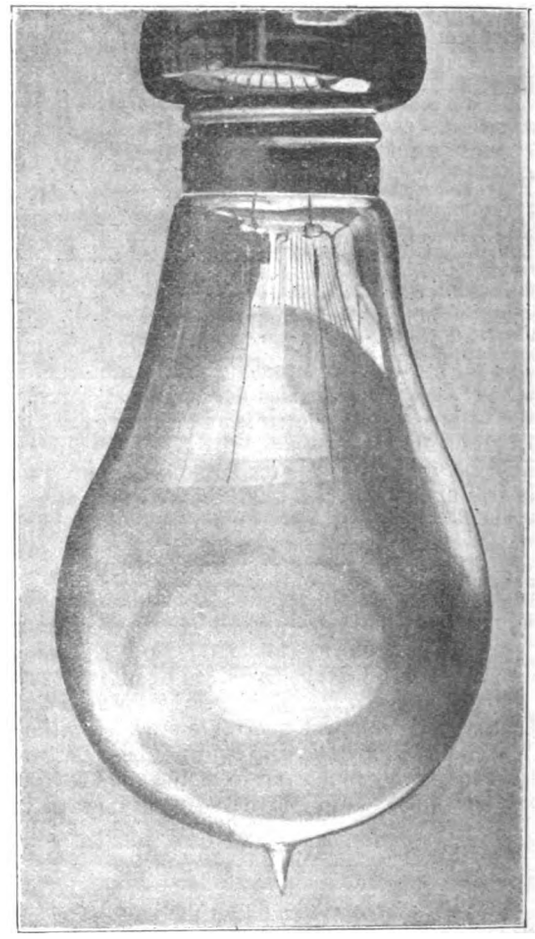
SIR: In trying to work out a satisfactory theory of the molecular receiver, or coherer, I have obtained several results which are suggestive and may prove of interest in practice. In the present letter I wish to draw attention to the reversal effect produced by electric radiation when the intensity falls below the critical value. If the receiver consists of a mass of metallic particles, it follows that the outside particles will exhibit the normal—say, the positive—effect; as the radiation gets absorbed in passing inwards, a reversed or negative effect may take place in the particles in the interior. The resultant effect will thus be a differential one. Some experiments I carried out seem to verify this deduction. Now, in long-distance space telegraphy the intensity of radiation is very feeble and near the critical value; hence it appears that, other things being equal, Prof. Lodge's method of single contact should theoretically be a more sensitive arrangement (there being no danger of any differential action) than the method of contacts in multiple.—Yours, &c. J. C. BOSE.

London, Sept. 18.

CARBON FILAMENTS AND LIGHTNING FLASHES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On my return from my holidays I notice your observations with respect to the effect of lightning storms on



electrical apparatus, and it has occurred to me that a peculiar case which has recently been brought under my notice might be of interest. If you think so, will you please make use of this communication. During one of the recent unusually heavy storms a flagstaff on the offices of the engineer of the line at Derby was struck; a short-circuit was established in the holders of two incandescent lights, and the safety fuses of the same were of course blown. The lamps in question

Digitized by Google

and the fuses applied to a "Ring" service employed in lighting the offices referred to. A few days subsequent to the occurrence attention was called to the appearance of one of the lamps—a peculiar configuration having appeared on the frosted portion. I have caused this lamp to be photographed, and I enclose photagraphs showing this peculiar condition. I am not sure whether to attribute this to deflagration of the filament. The appearance of the glass bulb which I am also sending you scarcely supports this theory, the marks being more like a stain than a deposit of carbon; the configuration, however, clearly follows that of the filament.

As the pecular condition of this lamp was not noticed immediately after the disruption of the fuses, I cannot, of course, say that it occurred at the same time, but from the fact that a short-circuit occurred at the same instant as that on which the flagstaff was struck and the safety fuses blown, it would appear that a highly-induced charge took place at the same moment in the "Ring" service, and it is probable that the effect on the lamp in question was then produced. The appearance of other lamps was as usual.

Although on the Derby station there are many instances in which the lighting of offices is effected by a "Ring" service, in no other case has anything peculiar arisen with the lamps in circuit, nor have any of the fuses been blown, nor, so far as can be ascertained, has the insulation of the service shown depreciation.—Yours, &c., W. Langdon.

Derby, Sept. 17.

[Beyond question, the shading on the lamp sent to us follows the shape of the filament. It might reasonably be supposed, therefore, to have originated with the filament; and the theory of deposition under the influence of the lightning flash appears quite probable. The lightness in tone of the deposit may arise from the extreme thinness of the carbon film.—Ed. *E.*]

TO THE EDITOR OF THE ELECTRICIAN.

Sir: With reference to the note in your issue of August 31, page 691, which commences: "A curious phenomenon has occasionally been observed in the glow lamps on the circuits of the Calcutta Electric Supply Co.," I should like to make a few remarks on the subject, as it is a phenomenon that I have frequently noticed, and from which I have experienced more serious consequences, which is probably accounted for by an experience of much heavier lightning storms in the Transvaal, where I have resided for the past seven years. Practically all the lighting circuits of the Transvaal mining companies are overhead, especially between the various buildings; and in scattered areas to the extent of some 300 yards or 400 yards in length. The system that seems to suffer mostly is the three-wire (which may be explained by higher E.M.F. being employed across the outer conductors, tends more readily to short circuit), the fault arising therefrom being the perforation of the insulation between the conductors in the flexible cords, which usually occur in series on both "legs" simultaneous, sweeping away a dozen lamps or more with one lightning flash; and oftentimes, after repeated flashes, a system is so deranged by the destruction of fuses, &c. (especially when the neutral is provided with a fuse) that the whole of the lamps on one leg have been destroyed.

With the two-wire system using from 100 volts to 120 volts the trouble seems to be minimised to the loss of a few individual lights.

For some time past I have contented myself with the explanation that the pulsating which the lights were subjected to was due to the effect of mutual induction between the lightning flash and the overhead conductor, which takes the form of a very high potential oscillatory current, which disappears entirely with the lightning flash (I am of a firm opinion that overhead conductors with their continuations, machines, &c., under the varying conditions with which they operate, are not capable of maintaining any static charge whatsoever); the E.M.F. and current value of the charge so generated being governed by the distance therefrom and direction that the lightning flash takes with respect to the direction and length of the overhead conductor, the greatest inductive effect taking place when the lightning flash takes a direction near about parallel to the overhead conductors.

The suggestion of the "coherer" theory being applied as an explanation is to my mind improbable for the following reasons:—

1. That lamps which are situated in close proximity to the generating station, with consequently short lines, are not so affected.

2. With very crooked overhead conductors, which pass from building to building, making a circuitous route, the pulsations are noticeable but usually do no damage.

3. With very straight lines pulsations are very great and usually accompanied with some damage.

If my memory serves me rightly, I have never known a low-tension armature used for lighting purposes to be burned out by lightning, whilst I have repeatedly seen punctures in the core insulation of 100-110-volt machines which I have have had for re-winding, the reason for which I have accounted to lightning discharges, the E.M.F. of the machine being insufficient to cause a short circuit by reason of the working current following the lightning discharge. However, I think the bulk of the discharge finds its way through the insulation of the conductors.

With transmission of power plants this phenomenon appears to me to take the same shape—in drum armatures almost without exception, two adjacent coils will be found to be burned out, short circuiting two diametrically opposite coils, oftentimes without injuring the core insulation. With ring armatures my experience has been the same, with the exception that they seem to stand much longer. I think that is due to the fact that the insulation of the diametrically opposite coils is much more perfect, having to pierce the core insulation twice.

I have frequently noticed with continuous-current transmission of power plants that when the machines at one end get damaged the other end invariably escapes; I attribute this to what I believe to be an important counter-effect which the "flow" or "return" current plays neutralising the inductive effect of the lightning flash in one conductor, and this accounts for the flow of the induced charge from one line to the other either by way of perforating the insulation between the coils of the armature diametrically opposite, or by discharging through the arrester to earth at one station, and from earth to the other line at the other station arrester, and completing the circuit by a simultaneous condenser action between the two conductors.

I will illustrate by describing some observations on the behaviour of a lightning storm on a 50-unit 500-volt continuous-current transmission of power plant, the property of the New Goch Mines (Ltd.) of Johannesburg.

The overhead lines are about 2½ miles long, the first ¾ miles being straight, subsequently turning through an angle of 120deg. for the remaining 1¾ miles, and extends from the company's mill engine house to their pumping station at Rosherville, the two stations being telephonically connected. At each station the machines are protected by double-pole lightning arresters, each pole being separately earthed.

The arresters are so constructed that any discharge can readily be seen, and its duration noted—in some instances I have observed discharges which continued for, I should say, between one and two seconds. Discharges were recorded from the + conductor at the generator end, and from the − conductor at the motor end simultaneously, and vice versa, some of the discharges being almost inaudible. Whilst these observations were being made the lightning storm was well overhead, and generator and motor kept running; when the current was switched off and switches kept out at both ends the discharges seemed equal from both wires and appeared at both ends alike.

Observations were made with a high-tension polyphase plant belonging to the same company, and with this, discharges appeared from all wires at both ends simultaneously.—Yours, &c., S. P. Blackmore.

Birmingham, Sept. 10.

MUNICIPAL, FOREIGN & GENERAL NOTES.

Aberavon.—A committee has been appointed to make application for a provisional electric lighting order.

Aberdeen.—The Corporation have adopted the report prepared by Mr. Bell in regard to the provision to be made for laying feeder and pilot cables from Dee Village to the different feeding points. Mr. Bell recommended the committee to authorise the building of a concrete subway above the new sewer which was to be laid in Crown-street and Portland-street, thus obviating the road being opened more than once. The estimated cost of the subway is put at from £5,400 to £6,600, according to the design adopted.

The Town Council have adopted the recommendation of the Electric Lighting committee to increase the salary of the city electrical engineer (Mr. J. A. Bell) from £300 to £350, increasing by annual increments of £50 to £500.

Ashton.—The local Ratepayers' and Property Owners' Association have resolved to oppose the Wigan and District Tramways Co.'s application for a light railway order unless they will undertake to construct the new line to the standard gauge, will efficiently light the route of the proposed railway electrically, or to pay to the township of Ashton a sum equivalent to such lighting.

Bermondsey (London).—The Vestry have approved the specifications of Messrs. Kincaid, Waller, and Manville for the steam dynamos and boosting and balancing sets, and for feed pumps and pipe work for their electricity works, and it has been decided to advertise for tenders. It is estimated that, with a battery of accumulators, the plant will have a capacity equivalent to 8,000 8 c.p. lamps alight. The Vestry are advertising for a resident electrical engineer at a salary of £250 per annum.

Bolton.—Mr. J. A. Day, the recently-appointed borough electrical engineer, will take up his duties on Monday next.

Bournemouth.—Application is about to be made for power to borrow £200,000 for the electric tramways to be constructed by the Corporation under their 1900 provisional order.

Bradford.—The Tramways committee recommend the Corporation to promote a bill for powers to construct extensions of the electric tramways.

Sanction to a further loan of £56,000 for electric lighting extensions has been received by the Corporation.

Buckie.—A representative of the North British Electricity Supply Co. is to wait upon the Burgh Commissioners to explain the company's electric lighting proposals.

Bury St. Edmunds.—The demand for electric current is being maintained, and Ald. Lake, chairman of the Electric Lighting committee, considers the prospects of the undertaking very satisfactory.

The police station is to be wired for the electric light.

Cannock.—Application is to be made for a provisional electric lighting order.

Cardiff.—The tramways pass into the hands of the Corporation on Jan. 1, 1902, and the Council have already obtained powers to adopt electric traction and to make extensions of the existing lines. Mr. Arthur Ellis, the recently-appointed electric tramway engineer, has promptly set to work and presented a report, in which he states that the work of equipment should be proceeded with without delay, and that the whole of the equipment and plant should be completed and ready for testing at least a month or six weeks before the system is opened for regular service. Considering the limited time to carry out the various works and the great difficulty in obtaining early deliveries of plant, &c., especially engines and generators and cars, Mr. Ellis has confined his report to the question of the type of plant to be adopted and to the site. The Roath Brook site has, he says, two most essential points in its favour, viz., its close proximity to a railway, and also to a brook. There was also ample room to make extensions, and there would be no difficulty in the distribution of power. He therefore advises the selection of the Roath Brook site for the power station. As to plant, he therefore makes the following recommendations: The engines to be of the compound vertical condensing type, running at a speed not exceeding 100 revs. per min., and fitted with Corliss valve gear. The generators to be of the compound type and mounted direct to the shafts of the engines between the high and low pressure cylinders. He recommends slow speed engines as a tramway load is constantly varying. In connection with the condensing plant Mr. Ellis recommends a cooling tower, for the following reasons: The Roath Brook is not of very great size, and is not of regular capacity throughout the year, although there is a good flow of water for nearly nine months in the year. In any case it would not be of sufficient capacity for the amount of plant which will be installed, nor of sufficient area to allow of the water being cooled after delivery from the condensers. By using a cooling tower the same water would be used over and over again, and any losses from evaporation would be made up from the water from the brook. In addition to this, during the greater part of the year the water from the brook could be used to feed the boilers. The boiler-house plant would consist of Lancashire boilers, economisers, superheaters, pumps, mechanical stokers, and coal conveying plant, the mechanical stokers and coal haulage plant to be driven electrically. In conclusion, Mr. Ellis states that what he has seen of Cardiff a very quick service would be necessary, and by making provision for this the receipts per car per day would be much greater than with a slow service. The committee have adopted the report, and Mr. Ellis has been instructed to prepare specifications for machinery, &c.

Crieff.—A provisional electric lighting order is to be obtained by the Council.

Devonport.—The Corporation will construct the tramways authorised by the provisional order of 1899 and the act of 1900, provided satisfactory arrangements can be come to with the Devonport and District Tramways Co. as to working, and the town clerk has been instructed to apply to the Board of Trade for an extension of 12 months of the time within which the tramway may be commenced and completed.

Douglas (Isle of Man).—In reply to a query as to the position of the electric lighting question in this town, the chairman of the Electric Light committee (Ald. W. Goldsmith) explains that the committee has been waiting in expectation of the electric tramway undertaking being offered for sale by the liquidator. He promised that the committee would have an early meeting and submit a report.

Electric Railways and Tramways in Germany.—In 1891 only three towns in the German empire possessed electric traction. In 1895 the number had increased to 33, in 1896 to 46, in 1897 to 62, in 1898 to 77, and in 1899 to 93. The length of tramways working at January, 1900, was 2,286 kilometres, and 837 kilometres were in course of construction.

Enfield.—The Council has resolved to apply for a provisional electric lighting order.

Farnworth (Bolton).—The foundation stone of the electricity generating station was laid by the chairman of the Electricity committee, Mr. W. B. Richardson, J.P., last week. The total cost of the electric lighting and tramway scheme is estimated at about £22,000, and Mr. Richardson said the Council had powers to construct about 6 miles of tramways in the district, and authority to lay tramways in other districts. An agreement had already been made with the Kearsley Council. The plant would be capable of generating current for the equivalent of 6,000 16 c.p. lamps, and a number of arc lamps for public lighting, in addition to the needs of the electric tramways.

Folkestone.—The Council are recommended to obtain powers to construct electric tramways involving an expenditure of about £95,000.

G.P.O. Telegraph Staff.—It is stated that important changes are about to be made in the internal arrangements of the Telegraph department of the General Post Office. Some of the leading newspapers have hitherto been allowed to monopolise the services of the most skilled of the Postal Telegraph Department operators, and no sooner does a male operator make himself thoroughly competent than he seeks and obtains a position on the "private wire" staff. The Postmaster-General has now, it is stated, decided that in future newspaper proprietors must provide their own telegraphists.

Huddersfield.—Application has been made to the Board of Trade to borrow £38,305 for converting two additional tramway routes to electric traction.

Ince (Lancs.).—The Council has decided to apply for an electric lighting provisional order. The South Lancashire Electric Supply Co. have also given notice of intention to apply.

Ipswich.—The Council have notified the Ipswich Tramway Co. of intention to exercise their powers of purchase under the Tramways Act, 1870.

Italy.—Extensive public works improvements are in hand at Bari, and it is anticipated that the gas lighting of the public thoroughfares will shortly be superseded by the electric light.

At Salerno Messrs. Sprecher & Co., mill owners, have put down an extensive electric generating plant, which supplies current for the public lighting of Carva and Vietri. A concession is being sought by a local firm of engineers for a scheme to divert the course of the river Tusciano for the generation of electric energy to provide current for an electric tramway from Salerno, through an extensive district, to Torre dell' Annunziata. 20,000 £10 shares are to be issued.

Kilmarnock.—Mr. F. B. Lea, the local representative of the British Electric Traction Co., attended at the meeting of the Council last week to explain the company's proposals to construct electric tramways between Beansburn and Riccarton, with a spur line from the Cross to Hurlford.

Digitized by Google

Lake District Electric Tramway Scheme.—The scheme of the British Electric Traction Co. to construct a light (electric) railway between Bowness and Ambleside has been withdrawn, to be revived in a modified form later.

Light Railways.—The Ormskirk and Southport Light Railway order has been submitted to the Board of Trade, and objections must be sent to the secretary, Railway Department, Board of Trade, London, by Oct. 11.

The promoters of the Loughborough Light Railway scheme (Loughborough and District Electric Traction Syndicate) have come to terms with the Council as to the amount to be contributed for streets improvements, and the order will now be issued by the Light Railway Commissioners.

Liverpool-street—Romford Electric Railway.—A rumour having been published that the Great Eastern Railway Co. have under consideration the construction of an electric line from Liverpool-street to Romford (to be submitted for parliamentary consent next session), Mr. J. F. S. Gooday, the general manager, has stated publicly that the company have no such undertaking in hand.

Lowestoft.—A bill for powers to construct a system of electric tramways is to be promoted by the Council. Application has been made to the Local Government Board for sanction to borrow £20,000 for electric lighting extensions.

Malta.—The revenue from the electric lighting department of the Malta Government for 1899 was £12,860, compared with £11,236 in 1898, an increase of £1,624. The revenue for 1897 (the first year of working) was £9,123.

"Men of Note in Commerce and Finance."—This is the title of a new biographical business directory edited by Mr. H. A. Bassett and published by Effingham Wilson, 11, Royal Exchange, London. Mr. Bassett has gathered together a mass of somewhat scrappy information regarding a large number of men engaged in "city" operations. Too many of the entries savour of the "Directory of Directors," and with regard to others, without unduly extending the size of the book some additional interesting particulars should undoubtedly have been furnished, more particularly as this is obtainable from other published works. Mr. Bassett has, so far as we have had time to check the entries, done his work very well, and those interested in the commercial men with whom they are in daily contact will find these brief sketches an inducement to seek elsewhere for more extended particulars. It is the fault of books of this kind that they must be very incomplete, and "Men of Note" is no exception to this rule.

Moss Side.—The Council have applied to the Local Government Board for sanction to borrow £10,870 for refuse destructor works.

Municipal Trading.—The evidence given before the Joint Select Committee of the Houses of Lords and Commons on Municipal Trading has just been issued in Blue Book form. As already announced, the Committee recommends that it should be re-appointed next session.

Nottingham.—The Corporation are converting the local tramways to electric traction on the overhead trolley system, and the *Nottingham Guardian* of the 15th contained a plan of the existing tramway routes and of the proposed extensions. The work will entail an estimated capital expenditure of £585,500, and the total length will be about 40 miles. Contracts have already been let, that for the cars having been placed with Messrs. Dick, Kerr & Co., the poles are being supplied by Messrs. John Spencer, of Wednesbury, the rails by Messrs. Bolckow, Vaughan & Co., and the points and crossings by Messrs. Askham Bros. and Wilson.

Plymouth.—A breakdown occurred at Plymouth electricity works last week, and as the somewhat circumstantial account of the accident in the local Press might lead to the assumption that the interruption was serious, the following particulars may be of interest: At about 3:15 p.m. on the 11th inst., the commutator on the dynamo side of the tramways negative booster flew into pieces. This was caused by the breaking of the gun-metal ring holding the commutator. The results were rather startling. A number of pieces went through the roof, smashing a lot of glass, while other pieces flew about the room in all directions. The brush gear was wrecked, the pedestal of the machine cracked right across, and the magnet and armature windings were considerably damaged. The conducting cables were also injured. The current was, of course, interrupted, and it took a little time to get it on again. Luckily nobody was hurt, although there were several narrow escapes. The machine was 4kw. capacity, and ran at about 1,400 revs. per min.

Presentation.—Mr. F. Kershaw, who has severed his connection with the Bradford Corporation electricity works in order to become chief assistant to Mr. A. H. Gibbings, was last week presented with a case of cutlery by the chief officials and staff at Bradford.

Rubber in Rhodesia.—According to a report recently presented to the British South Africa Co. by Mr. Lyttleton Gell, there are extensive tracts of natural rubber forests in north-west and south-east Rhodesia, the rubber product being of a high commercial value. In Southern Rhodesia indigenous rubber is reported in abundance in the Sabi Valley and along the Zambesi. Unfortunately the native methods of extraction here as elsewhere in Africa are very destructive to the trees, and the present methods of preparation of the rubber for market are very faulty, and reduce the market value of South African rubber considerably.

St. Helens.—The North-road and St. Helens Junction electric tramway routes are ready for Board of Trade inspection.

Salford Royal Technical Institute.—The calendar for the fifth session (1900-1) of this Institute is issued, and is a copiously illustrated and well-arranged publication. Information regarding the course of study in the day and evening classes available for students is given, the illustrations conveying an excellent idea of the efforts made to provide the necessary plant and apparatus for efficient instruction in the various branches of theoretical and practical work. Electrical and mechanical engineering, physics, &c., are well to the front.

Shoreditch (London).—The Lighting committee have been authorised to purchase 25 10-ampere and 25 25-ampere meters at a cost of £5 each.

Skegness.—The consulting engineer (Mr. W. C. C. Hawtayne) recommends the Council to apply for a provisional order, and a special meeting will be held to consider the matter. The North British Electric Supply Co. has intimated an intention to apply for an order.

Southampton.—The consulting engineers (Messrs. Kincaid, Waller and Manville) have been instructed to prepare specifications for the construction of two additional electric tramway routes. The estimated cost of construction, exclusive of cars, distributor mains and feeders, is put at £19,180.

South London Tramways.—The London County Council recently proposed to apply for Parliamentary powers to construct a tramway from Camberwell-green to Forest-hill provided the Camberwell and Lambeth Vestries and the Lewisham Board of Works agreed to contribute one-third of the cost (estimated at £155,450) of the necessary street widenings. The Lambeth Vestry have declined to entertain the offer.

The London County Council propose to seek powers to construct an electric tramway along the new street between Bermondsey New-road and Tooley-street, and have informed the Bermondsey Vestry that the making-up and paving of the carriageway of the new street will shortly be put in hand. In order to avoid breaking up the concrete of the carriageway for the purpose of laying the tramways, the Council propose that the construction of the electric conduits, drains, pits for road boxes and grooves for the rails be proceeded with at once in anticipation of powers being granted by Parliament, leaving the slot rails and tram rails to be laid when parliamentary sanction has been obtained. The paving between the rails is to be granite setts, "because, if the slot rails for the conduit are to be put down at a later date, wood paving will not be suitable." Bermondsey Vestry having approved the double track will ask the Council to take current from the Vestry's generating station, and reserve to themselves the right of action in regard to the system of traction until the Council's application comes before Parliament.

Stalybridge and Hyde Electrical Scheme.—It has been decided by the Stalybridge, Hyde, Mossley and Dukinfield Electric Traction and Lighting Joint committee to promote a bill for powers to construct a system of electric tramways in the towns named and to supply current for lighting. The consulting engineer for the scheme is Mr. A. H. Gibbings.

Teddington.—A provisional electric lighting order is to be applied for by the Council.

Torquay.—An electric tramway scheme, prepared by Mr. J. Taylor and estimated to cost about £50,000, is at present under the consideration of a sub-committee of the Electric Lighting committee.

Wednesbury.—The Council have formally notified the South Staffordshire Tramways Co. of their desire to purchase so much of the company's undertaking as lies within the borough of Wednesbury.

Workhouse and Asylum Lighting.—The Ormskirk Guardians have appointed a sub committee to report upon the question of adopting electric lighting.

The Local Government Board having intimated to the managers of the Poplar and Stepney Sick Asylum that they could not give consent to a loan for the electric lighting of the institution until an estimate of the cost of the work had first been obtained, this estimate has now been furnished.

The Brighton Corporation have referred a report of the resident electrical engineer (Mr. Christie) as to the electric lighting of the workhouse to a committee. At present there are about 1,000 gas jets in use. The capital cost of the whole installation, consisting of 1,000 lights wired, two 10 H.P. motors, and all accessories, is put at about £1,500.

Digitized by Google

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers, or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London:—

"The Art of Electrolytic Separation of Metals."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free. The author treats fully both the theoretical principles of the art of electrolytic separation of metals and the practical rules and details of technical application on a commercial scale. The work is adapted to the use of the manufacturer as well as the student.

"Electromagnetic Theory."—By Oliver Heaviside. *Vol. I.*, 12s. 6d. *Vol. II.*, 12s. 6d.

"Drum Armatures and Commutators," by Mr. F. Marten Weymouth. also ready. Price 7s. 6d., post free. Prospectus on application. This is a complete treatise on the theory and construction of drum winding, and of commutators for closed coil-armatures, together with a *résumé* of the principal points involved in their design, and an exposition of armature reactions and sparking.

"Electrical Engineering Formulæ," a pocket book, by Messrs. W. Geipel and H. M. Kilgour; price 7s. 6d.; by post, 7s. 9d.; abroad, 8s. *New Edition nearly ready.*

"Bibliography of X-Ray Literature and Research."—A valuable compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of general as well as special information bearing upon the whole subject of electrical discharge research. Edited by C. E. S. Phillips. Price 5s., post free.

"The Manufacture of Electric Light Carbons."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated, price 1s 6d.; post free, 1s. 9d. In this work the author gives useful hints as to the manufacture of electric light carbons, including the preparation of material, firing, saturating, and coring, together with a description and estimate of cost of the plant required.

"Localisation of Faults in Electric Light Mains."—By F. C. Raphael. Price 5s., post free. The book deals with the important subject of localising faults in electric light and power cables; and the various methods of insulation testing are here collected and discussed.

"Wireless Telegraphy: Signalling across Space without Wires by Electric Waves." A Review of the Work of Hertz and his Successors.—By Dr. O. J. Lodge, with a large number of illustrations, bringing this latest application of electrical science quite up to date. New and Enlarged Edition, 5s. nett. *Now ready.*

"The Centenary of the Electric Current, 1799-1899."—By Dr. J. A. Fleming. Price, paper covers, 1s. net, post free 1s. 3d.; strong cloth, 2s. 6d., post free.

"The Manufacture of Carbons for all Electrical Purposes."—by Francis Jehl. 10s. 6d., post free. This is a practical handbook, giving a complete description of the art of making carbons for electric lighting, electrodes, &c., with particulars of the various gas generators and furnaces used in carbonising. The work also contains particulars of the cost, &c. of erecting and working carbon works, and plans of a model factory.

"Motive Power and Gearing for Electrical Machinery."—By E. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free. In this comprehensive work an account is given of the scientific principles and modern practice in the use of engines for dynamo driving, not only for isolated power plants, but also for public electric lighting and power stations. The various forms of gearing in the power station and for electric motors are also dealt with; and the book contains, in addition, numerous tables giving exact data of the equipment and working of electric power stations.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. *New and Cheaper Edition*, 6s., post free.

"The Students' Guide to Submarine Cable Testing."—A new edition of this book, by Messrs. H. K. C. Fisher and J. C. H. Darby, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated.

"The Incandescent Lamp and its Manufacture."—By Gilbert S. Ram. Price 7s. 6d., post free. The principles underlying the manufacture of the incandescent lamp are carefully and fully dealt with in this volume.

"Magnetic Induction in Iron and other Metals."—By Prof. J. A. Ewing. Price 10s. 6d. net. *New Edition (Third) now ready.*

"Electric Motive Power," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. Price 10s. 6d., post free; abroad, 11s.

"Electrical Testing for Telegraph Engineers."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. Demy 8vo, fully illustrated. 10s. 6d., post free.

"Submarine Cable-Laying and Repairing. —By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d. This work gives a detailed technical summary of modern practice in manufacturing, laying, testing, and repairing submarine telegraph cables.

"The Alternate Current Transformer."—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. Vol. I.—*New Edition.* Price 12s. 6d., post free, Vol. II., price 12s. 6d., post free, is also ready.

"Armature Winding of Electric Machines."—By H. F. Parshall and H. M. Hobart. This work has been compiled from notes made by Mr. Parshall in his capacity as Chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables, 30s. post free.

"Temperature Coefficients of 'Conductivity' Copper." Compiled by Messrs. Clark, Forde and Taylor, consulting engineers. Strongly bound in cloth, 2s. 6d. net. Also a Sheet Table of Log. Reciprocals of Coefficients for Copper Resistances at different temperatures from 32°F. to 84·9°F. Printed on strong cardboard, 6d. net.

"Laboratory Notes and Forms."—We have ready a set of 40 Elementary and Advanced Exercises for use with Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of the series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net; in sets of any three, 1s. net; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net; or in handy portfolio, price 12s. net; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnics and other Science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper, and with less space for tabulated records, are issued at half the price of the original set.

"The Potentiometer and its Adjuncts": A Universal System of Electrical Measurement.—By W. C. Fisher. Fully illustrated. Price 6s., post free.

"The Electrician" Reading Case.—To hold four numbers of the Journal. Strongly bound, 1s. net; post free, 1s. 4d.

"Electro-Chemistry."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"The Steam Engine Indicator and Indicator Diagrams."—Edited and enlarged by W. Worby Beaumont. Price 3s. 6d., post free. This work is a concise guide to the objects, construction, and use of the steam engine indicator and to the interpretation of indicator diagrams.

"The Electrician" Primers.—In Two Volumes. Vol. I., Theory Vol. II., Practice. Price, stout paper cover, 2s. 2d. each, post free; cloth, 2s. 9d. Single Primers, 3d. each, post free.

IN THE PRESS.

"The Electric Arc."—By Mrs. Ayrton.

"Secondary Batteries, their Design and Manufacture."—By F. J Wade.

"Primary Batteries: Their Construction and Use."—By W. R. Cooper.

"Practical Telephony."—By Dane Sinclair and F. C Raphael.

"'The Electrician' Wireman's Pocket-book."—Edited by F. C. Raphael. *Nearly ready.*

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office no later than first post Thursday morning. New Catalogues, Price Lists and similar matter should be sent early in the week.]

TENDERS INVITED.

Ilford District Council invite tenders for direct-current meters and cutouts. Specification may be obtained from the clerk (Mr. John W. Benton), Council Offices, Cranbrook-road, Ilford, and specification can also be seen at (but not obtained from) the offices of the consulting engineer (Mr. W. C. C. Hawtayne), 9, Queen-street-place, London, E.C. Tenders to Mr. Benton by noon of Oct. 8. An advertisement contains further particulars.

Grimsby Corporation require tenders for wiring the Free Library. Specifications from the borough electrical engineer (Mr. W. A. Vignoles), with whom tenders must be lodged by Oct. 6. See advertisement.

Manchester Tramways committee invite tenders for cast-iron bases for tramway poles. An advertisement giving further particulars and specifications, &c., can be obtained from the general manager (Mr. J. M McElroy), Tramways Department, Town Hall, Manchester. Tenders to chairman of committee by Oct. 1.

Hoylake and West Kirby District Council invite tenders for the "free wiring" of premises in the district. An advertisement contains further particulars, and tenders must be sent to the clerk (Mr. Roderick Williams), District Council Offices, Hoylake, by Oct. 4.

Birkenhead Corporation invite tenders for the supply, delivery, and erection of feeder mains, &c. An advertisement gives further particulars, and specifications, &c., may be obtained from the borough electrical engineer (Mr. Wm. Bates), Bentinck-street, Birkenhead. Tenders to town clerk (Mr. Alfred Gill), Town Hall, Birkenhead, by 4 p.m. of Oct. 2.

Aberdeen Town Council invite offers for the manufacture and supply of 25 electrical tramcars, and equipments for six horse cars

Digitized by Google

about to be converted. Tenders must be in before 12 noon of Oct. 17. An advertisement elsewhere gives further particulars. Mr. J. Alex. Bell, Cotton-street, Aberdeen, is city electrical engineer.

Aberdeen Electric Lighting committee invite tenders for two 200kw. and one 420kw. direct-coupled continuous-current generators and one 120kw. balancing set. Willans engines in both cases. Tenders to city electrical engineer by Sept. 29.

The directors of the *Lancashire and Yorkshire Railway* invite tenders for supply of stores during the 12 months ending Oct. 31, 1901. Among the articles required are brake blocks, copper, india-rubber, iron castings, ironmongery, sundry tools, &c. Some information is given in an advertisement, and all further particulars and forms of tender may be obtained at the stores department, Osborne-street, Manchester. Tenders, addressed to the directors, must be lodged with the secretary (Mr. R. C. Irwin), Hunt's Bank, Manchester, by 10 a.m. of Monday, Oct. 8.

Wigan Corporation invite tenders for material for the equipment of their electric tramways, particulars of which are set out in an advertisement. Tenders must be sent to the borough electrical and tramway engineer (Mr. H. Collings Bishop) by 27th inst.

Bradford Corporation require tenders for an engine and dynamo, switchboard apparatus, &c., for their destructor works. Specification may be obtained from the city electrical engineer (Mr. R. A. Chattock), Town Hall, Bradford. Further particulars are given in an advertisement. Tenders to town clerk (Mr. Frederick Stevens) before Oct. 9.

Eray Urban District Council will on Oct. 4 receive and consider tenders for the supplies required at their electric light works for 12 months, including cables, house wires, switches, holders, incandescent lamps, &c., &c. Specification, &c., can be obtained of Mr. P. MacDonnell, clerk to the Council, Town Hall, Bray, Ireland, to whom tenders must be delivered before 10 a.m. of Oct. 4.

Walthamstow District Council invite tenders for electric lighting plant and apparatus, including gas plant, gas engines, dynamos, switchboard, boosters, balancer and measuring instruments. Tenders to vestry clerk by 5 p.m. Sept. 25.

Devonport Corporation invite tenders for two vertical engines, two 300kw. generators, balancer, battery, booster and motor, switchboard for lighting and traction, storage battery, and a 10-ton travelling crane. Tenders to town clerk by 5 p.m. 26th inst.

Sheffield Corporation invite tenders for : (*a*) Two 600kw. two-phase steam alternators and exciters, and (*b*) alteration of present single-phase plant to two-phase. Tenders to chief engineer and manager of electric supply department (Mr. S. E. Fedden) by Oct. 6.

Dublin Electric Lighting committee invite tenders for electricity supply mains and accessories. Tenders to town clerk by 4 p.m. Oct. 4.

Dublin Corporation invite tenders for power machinery at Ringsend, including pumping engines and pumps, boilers, electric motors and pumps. Tenders to town clerk by noon Oct. 3.

Eastbourne Corporation invite tenders for water-tube boilers, with fittings, feed pumps, &c. ; 400kw. steam alternator, with exciter (vertical enclosed high-speed engine) ; and main switchboard and connections. Tenders to town clerk by noon Oct. 4.

Long Eaton Council require tenders for establishing telephonic communication between their waterworks pumping station, Stanton-by-Bridge, near Derby, and the service reservoir at Castle Donington. Tenders to surveyor by Oct. 1.

St. John, *Hampstead* (London) Vestry, invite tenders for eight dry-back marine boilers, steam and water pipes, feed pumps, &c. Tenders to vestry clerk, by 4 p.m. Sept. 27.

Salford Electric Light committee invite tenders for seven iron transformer chambers. Tenders to chairman of committee by 10 a.m. 24th inst.

Brighton Corporation invite tenders for 25 electric motor-car bodies, trucks, and electric-motor equipments, and also for steel girder tramway rails, fishplates, and joints. Tenders by Oct. 1.

Hull Electric Lighting committee invite tenders for steam and water pipes, feed-pumps, &c. Tenders (addressed chairman of committee) to town clerk's office by noon Sept. 27.

Medomsley (Durham) Parish Council invite tenders for the electric lighting of the road leading from Black Hall Mill to Medomsley. Particulars from the clerk (Mr. M. T. Milburn).

Tenders are invited for an overhead travelling crane and an economiser for the *Dundee* electric lighting station. Tenders to clerk to Gas Commissioners by noon, 26th inst.

Tunbridge Wells Council invite tenders for the erection of a chimney shaft at the electricity works. Tenders to town clerk by 24th inst.

Hackney (London) Vestry invite tenders for the constructional ironwork for their electricity and refuse destructor works. Tenders to vestry clerk by Oct. 3.

Hackney (London) Electric Lighting committee invite tenders for electricity supply mains. Tenders to vestry clerk by 5 p.m. Oct. 3.

Nottingham Corporation require tenders for the erection of a new power station. Tenders to city engineer by 21st inst.

Middleton Council invite tenders for erection of electricity station buildings. Tenders to town clerk by Oct. 11.

Fulham (London) Vestry invite tenders for coal handling plant at their electricity works. Tenders to clerk by 6 p.m. 25th inst.

Tenders are invited for wiring the *Suffolk* County Asylum, Melton. Tenders to Mr. A. T. Cobbold, County Hall, Ipswich, by Oct. 5.

Varna (Bulgaria) Municipal Council invite tenders for the electric lighting concession for 40 years. Tenders by Oct. 15.

Fuenteovejura (Cordova, Spain) municipal authorities invite tenders until Oct. 9 for the electric lighting concession for 20 years. Tenders to el Secretario del Ayuntamiento.

TENDERS RECEIVED AND ACCEPTED.

As stated in our issue of the 7th inst., the Salford Corporation have placed an order with Messrs. W. T. Glover & Co. for the supply and laying electric lighting cables, tramway feeders, and street-lighting accessories for £159,684. 12s. 8d. The adoption of report of the committee recommending the acceptance of the tender was moved by Ald. Shaw, who said Messrs. Glover's tender was the lowest which conformed to the specification, and the cables would be subjected to the test mentioned in the specification before they were taken over. Councillor Higson said there was one tender lower than Messrs. Glover's, but the reason it was not accepted was because it was proposed to substitute tar in place of a bituminous compound. The British Insulated Wire Co. were £650 lower, but their tender did not conform to the specifications. He congratulated the Council and Messrs. Glover that they had a firm within the boundaries of their borough capable of undertaking the work. The mayor said he was pleased there were local firms capable of carrying out the Corporation contracts. Local firms like Mather and Platt, Galloways, and some others could do their work, and it was pleasant to think that they were practically employing their own people. The resolution was carried.

Poplar and Stepney (London) Sick Asylum District Managers have received the following tenders for the installation of telephonic communication at the asylum :—

G. Weston & Co. (*accepted*) ...	£135	London & Prov. Telephone Co.	£176
Private Wire & Tel. Instll. Co.	191	Barlow Bros. & Co.	175
F. Emerson & Sons	188	V. G. Middleton	165
Palatine Telephone Co.....	185	G. W. Lummis-Paterson & Co.	163
Strode & Co.	183	Julius Sax & Co.	160
Consol. Telephone C. & M. Co.	182	Cox-Walkers	158

Messrs. Weston & Co. subsequently asked permission to withdraw their tender on the ground that a mistake had been made in their estimates. A decision on this point will be given at the next meeting of the managers.

Aberdeen Town Council have accepted the following tenders for the supplying of tramway rails, fishplates, tie-bars, and bolts and nuts :—

Bayliss, Jones and Bayliss (20 tons bolts and nuts)	£16	10	0	per ton.
A. and J. Main & Co. (35 tons steel tie-bars)	12	7	6	do.
P. and W. Maclellan (fishplates)	8	13	9	do.
Ditto (straight rails)	7	13	9	do.
Ditto (curve do.)	7	13	9	do.

The following tenders were received by the Southampton Guardians for supplying the generating plant and wiring the new workhouse infirmary :—

Lankester & Son (*accepted*)	£3,499	10	0	Nat. Elec. Wiring Co.	4,890	0	0
Maple & Co.....	5,494	5	6	F. Troy & Co.	4,825	0	0
Gifkins & Co.	5,465	0	0	Lea and Warren	4,500	0	0
T. F. White	5,406	2	6	Cox Walkers.....	4,254	0	0
H. M. Ashton	4,998	0	0	Shalders and Davis...	4,100	0	0
Crompton & Co.	4,950	0	0	Drake and Gorham...	4,058	0	0
				Foote and Milne	4,056	0	0

Nuneaton and Chilvers Coton Council have accepted the following tenders :—

Babcock and Wilcox (boilers)	£1,060
Edmund Charrington (switchboard)	391
Clarke, Chapman & Co. (new armature)	66
Nuneaton Engineering Co. (crane)	120

As stated in our last issue, the tender for accumulators has been given to the Hart Accumulator Co.

Bradford Tramways committee recommend the acceptance of the tender of MM. V. Demerbe & Cie. for the supply and laying on the Demerbe system the rails for the Farsley, Thackley, Idle, Clayton, Quensbury and Manchester-road tramway routes. The rails are, however, to be rolled in England.

Glasgow Corporation have accepted the tender of Messrs. Chamberlain and Hookham for the supply of 150 2-ampere electricity meters at £3. 10s. each, and that of the Callender Co. for the supply of half-mile of 0·5 sq. in., and half-mile of 0·25 sq. in. lead-sheathed

Digitized by Google

cable, and 5 miles of telephone wire, and 1 mile of 0·15 sq. in. triple concentric cable, at £335, £176, £275, and £651 per mile respectively.

A contract for the supply of the storage battery required by the committee of management of the Kensington and Knightsbridge and Notting Hill Electric Lighting Companies in connection with their Wood-lane works has been secured by the Hart Accumulator Co.

Messrs. Lowdon Bros. & Co. have obtained the contract for the overhead equipment of about 10 miles of light (electric) railway at Southend-on-Sea. The line is to be opened in April.

Heywood Council last week accepted a tender for the supply and erection of electricity generating plant at £8,389.

Birkenhead Corporation have accepted the tender of Mr. J. Merritt for the erection of an electric tramway car shed at £10,183.

APPOINTMENTS VACANT AND FILLED.

Royton District Council are considering the advisability of applying for provisional orders for electric lighting and traction, and invite applications from engineers for preparing plans, &c. An advertisement gives some particulars, and all further information may be obtained from the clerk (Mr. Thomas Bleasdale), Town Hall, Royston, near Oldham.

Bermondsey (London) Vestry require a resident electrical engineer. Further particulars are given in an advertisement, and applications must be sent to the clerk (Mr. Frederick Royal), Town Hall, Bermondsey, London, S.E., by noon Oct. 3.

Fleetwood District Electric Light and Power Syndicate require a shift engineer. Applications to Mr. Oswin Hansom, resident engineer, Electricity Works, Fleetwood, Lancs. See advertisement.

A shift engineer is required for the Rathmines (Co. Dublin) electricity works. Applications to resident engineer (Mr. G. F. Pilditch), by 24 inst.

Birmingham Small Arms Co. require an assistant electrician. See advertisement.

A traveller is required by a firm of electric wire and cable manufacturers for the Midlands and South of Yorkshire. See advertisement.

A lecturer and demonstrator in physics is required for University College, Nottingham. Applications by 25th inst. to secretary. See advertisement.

The Council of Hartley College (Southampton) invite applications for the appointment of assistant lecturer in engineering. Applications to clerk (Mr. D. Kiddle) by Oct. 3. See advertisement.

A science master is required for the Kilmarnock Academy. Applications to clerk by Oct. 1.

A junior demonstrator in physics is required for Owens College, Manchester. Applications to the Registrar by 24th inst.

Mr. H. W. Angus, chief assistant at Bolton, has been appointed borough electrical engineer by the Eccles Town Council.

Mr. A. J. Oridge, of Brighton, has been appointed meter superintendent of the Sheffield electric lighting department.

The British Thomson-Houston Co. have appointed Mr. T. W. Sheffield district manager of their branch depôt recently opened at Trevelyan Buildings, Corporation-street, Manchester.

BUSINESS NOTICES.

Messrs. Doherty and Donat, engineers and contractors, 40, South King-street, Manchester, are the sole licensees for Great Britain for "Zschocke's" patent water cooling towers, and we are informed that already cooling plants representing over 600,000 I.H.P. (including 35 electric lighting and power stations) are in successful operation all over the world.

BANKRUPTCIES, LIQUIDATIONS, &c.

A meeting of the Woodlands Electric Co. (Ltd.), will be held at 10, Berey's-buildings, Church-street, Liverpool, on Oct. 15, to receive an account of the winding-up. Mr. F. J. Armstrong is liquidator.

In the bankruptcy of E. B. Pym, electrical engineer, 29, Bramham-gardens, London, S.W., lately trading at Bar-chambers, Scarborough, the trustee, Mr. A. H. Wildy, has been released.

In the bankruptcy of E. M. Winter, electrical engineer, Amberley House, Norfolk-street, London, W.C., the trustee, Mr. A. H. Wildy, has been released.

Claims against A. G. Inrig, electrical engineer (trading as the Globe Electrical Co.), 46, White Post-lane, Victoria Park, London, E., must be in by Oct. 2. Mr. E. H. Hawkins, 3, Barbican, E.C., is trustee.

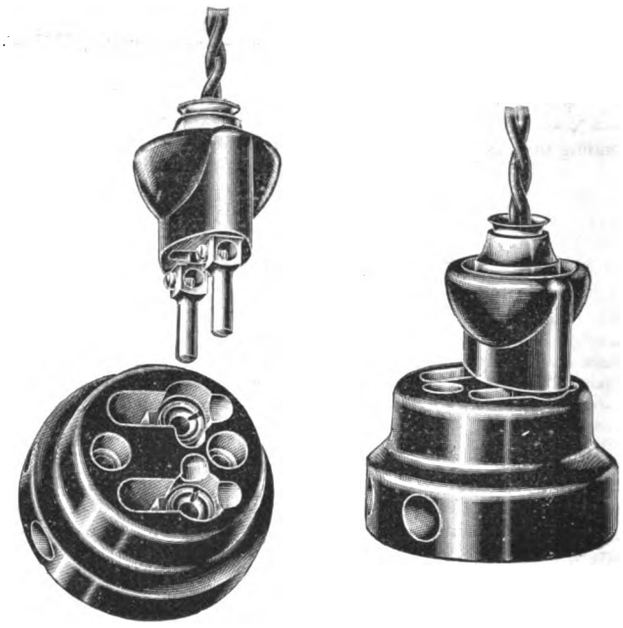
A first and final dividend of 2s. 1½d. will be payable on 26th inst., at the O.R.'s, 31, Manor-row, Bradford, in the bankruptcy of Herbert Sewell, electrician, &c., Clifton-place, and 63, Birkland's-road, Shipley.

Engineering Works for Sale.—Our advertisement columns contain particulars of engineering works in the city of Dublin which are offered for sale by tender as a going concern owing to the death of the late proprietor. The works are centrally situated and have a suitable set of offices, pattern shop, machine shop and foundry, and smith's shop, together with a number of tools which are all of modern type, many of them being new. Tenders are to be addressed to Mr. A. Basil Wilson, M.I.C.E., Maryville, Malone, Belfast, from whom further particulars can be obtained.

Plant for Sale.—Mr. Gabriel Moon notifies in an advertisement that he will sell by auction on Tuesday, 25th inst., the whole of the Earlestown public electric lighting and generating plant, together with the stock-in-trade of an electrical engineer and contractor. Sale commences at 11 a.m. Catalogues from the trustee (Mr. George F. Clarke), Cross-lane, Earlestown, and Hardshaw-street, St. Helens, or from the auctioneer, Earlestown, Newton-le-Willows.

Johnson and Phillips' Cables.—Johnson and Phillips Electric Cable Works announce that, in consequence of a slight fall in the market price of raw materials an additional 5 per cent. on the trade discounts previously allowed off vulcanised rubber cables listed in the firm's February, 1900, catalogue can now be allowed. A well got-up new list (No. 10, September, 1900) of Johnson and Phillips' cables is now available. The additional cable factory for the manufacture of lead-covered and armoured cables for town lighting is now completed and in working order, and a contract for the Manchester Corporation is being executed.

I.E.C. High-Voltage Wall Plug.—The change from low-voltage to high-voltage supply has required that special attention should be given to accessories suitable for the increased voltage, and for a new wall plug manufactured by the International Electric Co., 55, Redcross-street, Barbican, London, E.C. It is claimed that, as far as insulation is concerned, it will answer the most stringent requirements of central station engineers. Arcing or short-circuiting is, it is contended, an impossibility, as all the current-carrying parts are deeply embedded in and surrounded by china, there being no metal parts at the back of the china base. The plug itself is provided with this firm's patent porcelain cord grip. The price at which the plug is supplied complete to the trade is a low one, and supply station engineers can obtain samples free of charge on request.



The New I.E.C. High-Voltage Wall Plug.

Electrical Supplies.—Messrs. Krupka and Jacoby send us their latest list relating to Lessing dry batteries, carbons for arc lamps and other electrical purposes, manufactured by Dr. Alb. Lessing, of Nurnberg, for whom Messrs Krupka and Jacoby are sole agents for the United Kingdom and Colonies. The same firm send a list of "Siemens" incandescent lamps, of which a large stock is held.

Aluminium.—The display at a number of stands at the Paris Exhibition of a variety of goods manufactured from aluminium calls attention to the advance which has been made in a quiet way in this branch of industry. Apart from the excellent exhibit of the British Aluminium Co. (who, by the way, have secured a gold medal for their aluminium exhibit) there is to be seen in the exhibits of a number of leading British firms some excellent examples of repoussé and all kinds of hand-hammered aluminium work for a variety of indus-

Digitized by Google

trial, ornamental and domestic uses. At Messrs. Thomas Bolton & Sons' stand there is a fine collection of tubes and wires in aluminium, and also a large coil fixed to a large still, of which a number have been supplied by the British Aluminium Co. for use in the making of acetic acid, aluminium having been found very suitable for this apparatus. Among the miscellaneous aluminium displays may be particularised door furniture, fittings for light vehicles, wire, bicycle parts, a ship's propeller, &c., and an interesting exhibit is a portable water steriliser made in aluminium and specially designed for use in connection with the present military operations in South Africa. This steriliser weighs only 25lb., and is capable of producing 200 gallons of good drinking water per day. It is stated that several examples of this apparatus have been used with satisfactory results. The British Aluminium Co. have two stands at the exhibition, the stand on the ground floor being confined chiefly to raw material and that on the first floor to manufactured goods. Both stands are in group XI., classes 63 and 64.

"**New Lamps for Old.**"—An interesting circular is issued by the Renewable Electric Lamp Co. (Ltd.), Brunswick-place, City-road, London, N., which lampdealers and users may wish to obtain. Copies will be forwarded free on application to the company.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Sept. 12 to Sept. 18, with the ports of destination :—

Africa—Cape Town, £620 ; Durban, £1,143 (including £442 telegraph apparatus) ; Port Elizabeth, £25. *Argentina*—Buenos Ayres, £27. *Australasia*—Adelaide, £75 ; Auckland, £86 ; Fremantle, £255 ; Melbourne, £1,070 (including £994 telegraph material) ; Sydney, £1,026 (including £624 telegraph material) ; Wellington, £2,408. *Austria*—Trieste, £365 (telegraph cable). *Belgium*—Ostend, £70. *Ceylon*—Colombo, £44. *China*—Shanghai, £165. *Denmark*—Copenhagen, £61 (telegraph wire). *Germany*—Hamburg, £110. *Gibraltar*—£20. *Holland*—Amsterdam, £160 ; Rotterdam, £74 (telegraph wire). *Hong Kong*—£304 (including £202 telegraph material). *India*—Bombay, £71 ; Calcutta, £275 ; Madras, £159. *Japan*—Kobe, £296 ; Yokohama, £13,692 (including £13,284 telegraph cable). *Mauritius*—£30. *Straits Settlements*—Singapore, £33. *United States*—New York, £300. Total £22,964, against £15,476 in the corresponding week last year (Sept. 13 to Sept. 19).

PATENT RECORD.

The following list of Applications for Patents and Specifications published has been compiled for this journal by MESSRS. J. C. CHAPMAN and Co., *Chartered Patent Agents, of 70, Chancery-lane, W.C., from whom any available information in connection with Patents, Designs, and Trade Marks may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned Applications are not open to public inspection until after the acceptance of the complete Specification. The names within parentheses are those of communicators of inventions. When complete specification accompanies application, an asterisk is affixed.*

July 19, 1900.

13,010. W. JAMIESON and THE SCOTTISH WIRELESS ELECTRIC SYNDICATE (LTD.). Glasgow. Improvements in high-voltage fuses.
13,014. H. OPPENHEIMER. London. Improvements in and connected with fuses or cutouts for high-voltage circuits. (Actiengesellschaft Mix and Genest, Germany.)
13,015. H. OPPENHEIMER. London. Improvements in and connected with insulated bases for switches. (Actiengesellschaft Mix and Genest, Germany.)
13,020. E. VAN HAANEN. Manchester. Apparatus for generating dynamical electricity by means of the direct influence of steam.
13,021. E. GARDNER, T. H. GARDNER, and L. GARDNER. Manchester Improvements in electric ignition devices for internal explosion engines.
13,024. A. E. SEGNITZ. Birmingham. Improved means for starting and stopping electro motors.
13,031. A. REAME and C. WOKES. London. An improvement in or connected with laminated electric switches.
13,035. A. E. BEST. London. Improvements in or connected with apparatus for electrically igniting miners' safety lamps.
13,036. H. F. JOEL. London. Improvements in dynamo electric machines and electric motors.
13,044. SIEMENS BROS. & CO. (LTD.). London. An improvement in electric railways in which transformers are carried on the train. (Siemens and Halske Aktien Gesellschaft, Germany.)*
13,048. W. B. ELLIOTT and J. W. ESKHOLME. London. Improvements in and relating to means for controlling the speed of electro motors.*
13,049. E. SCHATTNER. London. Improvements in maximum demand electricity indicators.

July 20, 1900.

13,081. P. J. PURDY. Manchester. Improvements in means for grinding and truing up dynamo commutators and the like.
13,085. A. PARIETTI and A. R. DURANTE. Manchester. Improvements in the method of, and means for, sounding alarms on electric tram and motor cars.
13,095. R. MACRAE and H. C. MACRAE. London. Storage battery electrode.*
13,102. W. A. PHILLIPS and C. E. KENT. London. Improvements in and relating to electrical conductors.
13,103. W. A. PHILLIPS and C. E. KENT. London. A new or improved method and means for fire-proofing insulated wires and cables.
13,104. W. A. PHILLIPS and C. E. KENT. London. Improvements in means for covering wires and cables.
13,105. W. A. PHILLIPS and C. E. KENT. London. Improvements relating to the covering of electrical conductors.
13,106. F. T. HOLLINS. London. Improvements in safety devices for electric interlocking or block signalling apparatus.
13,125. R. HACKING. London. Improvements in automatic cutouts or combined cutout and shunt switches for overhead trolley wires for electric traction overhead electric cables or the like.
13,134. A. H. WALTON. London. Improvements in and relating to electric arc lamps. (Date applied for under Patents, &c., Act, 1883, sec. 103, Dec. 21, 1899, being date of application in United States.)*
13,143. THE THOMSON-DAVIS TELEPHONE SYSTEMS (LTD.) and A. T. M. THOMSON. London. Improvements in telephonic signalling apparatus applicable also to other purposes.

July 21, 1900.

13,184. A. BROOK. London. The Elland electric "railway" fog signal.
13,195. G. H. SMITH. London. Improvements in electrolytic apparatus for the production of caustic soda.
13,198. B. CRUVELLIER. London. Improvements in electric traction.*

July 23, 1900.

13,237. A. SOUTH. London. Improvements in electrical tatooing apparatus also applicable to stencilling or engraving.
13,249. W. FRIESE-GREENE. London. Improvements in and connected with the electrical transmission of images and in the recording of images.
13,280. J. F. ACKERMANN. London. Improvements in arc lamps.*

July 24, 1900.

13,344. T. B. LAMBERT. London. Improvements in the process of and apparatus for reproducing phonographic records.*
13,356. W. P. THOMPSON. Liverpool. Improvements in telephonic relays. (J. Tice, W. G. Urmson, J. W. Parsons, and H. A. Bell, United States.)*

July 25, 1900.

13,375. H. F. ATKINS. Coventry. Improvements in or relating to electric ignition plugs.
13,385. C. T. DRIGGS. Kingston. Improvements in the method of and means for medically applying electricity.
13,401. C. D. ABEL. London. An improved electrical converting transformer. (La Société Anonyme pour la Transmission de la Force par l'Electricité, France.)
13,415. C. A. LÓPEZ. London. Improvements in and in the manufacture of electric insulators.*

July 26, 1900.

13,447. C. CAREY-GIBSON. London. An improved electric tramway system employing alternating currents, preferably polyphase.
13,448. A. T. WEDELIN. London. Electricity used in tanning.
13,472. A. MUIRHEAD. London. Improvements in telegraphic transmitting, receiving and translating arrangements.
13,478. H. F. HUNT. Birmingham. Improvements in electric motor starting and regulating switches and cutouts.
13,479. J. T. ARMSTRONG and A. ORLING. London. Improvements in and relating to aerial conductors and like apparatus for transmitting and receiving electromagnetic impulses.
13,482. E. BEDE. London. Improvements in current collectors for electric traction.

July 27, 1900.

13,496. W. F. JONES. London. Improvements in electric switches.
13,515. R. HACKING. London. Improvements in or relating to overhead trolley wires or conductors for electric traction, overhead electric cables or the like.
13,533. E. DRAULLETTE. London. Improvements relating to electric motor vehicles.
13,538. J. G. LORRAIN. London. Improvements in or connected with current arresters. (P. C. Burns, United States.)*
13,539. J. G. LORRAIN. London. Improvements in or connected with current arresters and alarms. (P. C. Burns, United States.)*
13,540. P. MANGUIN. London. Improvements in electric igniting arrangements for internal combustion engines.

July 28, 1900.

13,573. E. T. PARKER. Wolverhampton. Improvements in apparatus for electrically lighting railway trains.
13,585. P. MANGUIN. London. Improvements in electric ignition devices for internal combustion motors.
13,592. H. HILL. London. London. Improvements in or relating to electric light fittings.
13,608. G. NAST. London. A new or improved current receiver or trolley for electric railways with overhead-current conducting system.

Digitized by Google

July 30, 1900.

13,636. W. E. Cocks. London. Combined electric alarm switch and air-brake coupling.
13,637. A. Schoeller. London. An improvement in inductors or like apparatus having an oscillating armature.
13,639. A. G. Bloxam. London. An improved electric motor. (La Société Ch. Mildé Fils & Cie., France.)
13,643. C. Maréchal, J. Michel, and E. Dervin. London. Improvements in wireless telegraphy.*
13,652. R. J. Gülcher. London. Improvements in and in the construction of electrodes.
13,656. R. W. James. London. Improvements in and relating to the electrodes of accumulators and the manufacture thereof. (J. J. Heilmann, France.)
13,661. W. R. Renshaw. London. Improvements in tramcars, railway cars, or locomotives and the like, driven by electric or other motors.

July 31, 1900.

13,679. B. M. Drake, E. G. Sheppard, and The Nernst Electric Light Co. (Ltd.). London. Improvements in holders for electrolytic incandescent lamps.
13,680. S. L. Powell and The Nernst Electric Light Co. (Ltd.). London. Improvements in series resistances for electrolytic lamps.
13,692. T. A. Edison. London. Phonographic recorder.*
13,693. T. A. Edison. London. Process of and apparatus for duplicating phonographic records, also applicable for other purposes.*
13,709. H. Oppenheimer. London. Improvements in and connected with index arrangement for telephone subscribers. (Actiengesellschaft, Mix and Genest, Germany.)
13,720. The British Thomson-Houston Co (Ltd.). London. Improvements in methods of operating dynamo-electric machines. (F. G. Berg, United States).*
13,721. The British Thomson-Houston Co. (Ltd.). London. Improvements in systems of electric motor control. (C. L. Perry, United States.)*
13,722. A. W. Staveley and I. H. Parsons, trading as Gent & Co. London. Improvements in contact devices chiefly designed for use in connection with electrical counting or recording devices.
13,732. W. M. Mordey and G. C. Fricker. London. Improvements in electricity meters.
13,751. C. Sintas and E. E. Schultz. London. A new or improved automatic device for the safe operation of electric conductors with or without guard wires.*
13,758. T. H. Hill. London. Improvements in incandescent electric safety lamps.
13,765. J. Shoecraft and C. C. Gardiner. London. Improvements in automatic electric block systems for railroads.

August 1, 1900.

13,805. G. Wright and C. Aalborg. London. Improvements in insulating supports for electrical conductors. (Date applied for under Patents, &c., Act, 1883, Sec. 103, Jan. 2, 1900, being date of application in United States.)
13,810. A. Bosshardt. Manchester. Improvements in trolleys for electric traction having three wires for triphane currents. (L. Gerard, Belgium.)
13,811. H. Hillischer. London. Improvements relating to underground electric conduits.
13,816. W. O. Rooper. London. Improvements in or connected with storage batteries.*
13,820. E. F. Moy and P. H. Bastie. London. Improvements in or relating to starting switches and automatic controllers of electromotors.
13,822. F. M. Lewis. London. Improvements in alternating-current electro-motors.

August 2, 1900.

13,839. E. M. Drake and The Nernst Electric Light Co. (Ltd.). London. Improvements in glow bodies and heaters for electrolytic incandescent lamps.
13,860. T. S. Perkins. London. Improvements in controllers for electric motors. (Date applied for under Patents, &c., Act, 1883, Sec. 103, Jan. 13, 1900, being date of application in United States.)
13,873. G. H. Whittingham. London. Improvements in electric switches.*
13,874. G. H. Whittingham. London. Improvements in automatic circuit controllers.*
13,892. V. I. Feeny. London. Process for the production of heating bodies for exciting electrical incandescence bodies made of second-class conductors. (Allgemeine Elektricitats Gesellschaft, Germany.)*
13,911. J. R. Dick and The Reason Manufacturing Co. (Ltd.). London. Improvements in electrical demand indicators. (Partly by A. Wright, on the high seas.)

SPECIFICATIONS PUBLISHED.

Note.—All Specifications can now be obtained at the uniform price of 8d. each.

1899.

18,414. Greil and Audiger. Electric contacts or current-taking devices.
18,475. Tidswell. Guards for electric tramcars and other tramway vehicles.
18,555. Slack. Splicing ears and terminals for overhead electric trolley wires employed on electric tramways.
18,892. Johnson (Hartmann and Braun). Electrical damping apparatus.
20,214. Vogelsang. Electrolytic bleaching of baled yarns.
20,227. Taylor. Collectors and conduits for electric tramways.
20,587. Maxim. Electric railway conduit systems.
21,302. Sondermann and Berlow. Electricity measuring instruments.
21,470. Mühlberg. Automatic charging device for electric motor carriages.
21,773. Rowntree. Electrically controlled elevators or lifts.
22,607. Beckmann. Manufacture of lead peroxide, and its application to electrical storage batteries.
23,497. Von Madaler. Gramophones.
23,877. De Thiersant and Norballe. Electric gas lighters.
24,536. Gottscho. Thermo-electric piles.
25,362. Thompson (Sinding-Larsen). Method of telegraphing on telephone lines, and telegraphic recorders for use in connection therewith.

NEW COMPANIES, STATUTORY RETURNS, &c.

ACCUMULATOR INDUSTRIES (LTD.)—This company was registered on Sept. 12, with a capital of £10,000 in £1 shares, to adopt certain agreements, and to carry on the business of electrical and general engineers, manufacturers of electrical accumulators, motors, controllers and vehicles, dynamo manufacturers, wire drawers, electro-platers, &c. The first directors are H. Leitner and B. Kuttner.

BRITISH POWER, TRACTION AND LIGHTING CO. (LTD.)—This company was registered on Sept. 15, with a capital of £52,000, in £1 shares, to take over certain businesses (including that of the Eclipse Brass and Copper Co. (Ltd.) and the Power Transmission and Traction Co.), and to carry on the business of electrical and general engineers, motor, motor car, crane, and lift manufacturers, &c.

ELECTRO-CERAMIC SYNDICATE (LTD.)—This company was registered on Sept. 11, with a capital of £2,000, in £1 shares, to acquire from Mr F. J. Shippey and Messrs. Shippey Bros. (Ltd.) the benefit of certain inventions and processes relating to electro-ceramic photography, chinagraphy, &c., and to manufacture and deal in photographic china plaques, electro-ceramic china, china and glass ware of all kinds, electrical and scientific apparatus, &c. The first directors are E. B. Koopman, W. T. Smedley, and A. Shippey.

MEYRA ELECTRIC CO. (LTD.)—This company was registered on Sept. 12 with a capital of £10,000, in £1 shares, to enter into an agreement with P. Meyer, to acquire the trade mark "Meyra," and certain inventions and processes relating to galvanic and dry batteries, and to carry on the business of electrical and general engineers, founders, chemists, &c. The subscribers are G. T. B. Cobbett, P. Meyer (electrician), O. Kopp (electrician), R. S. White, O. Percy, G. H. Homan, and S. Bridgwater (engineer). The first directors are G. T. B. Cobbett, O. Kopp, S. Bridgwater, and P. Meyer.

SUNBEAM LAMP CO. (LTD.)—The annual return to Aug. 24 has been filed. The capital is £25,000, in £10 shares, 1,765 of which have been taken up. £10 has been called up and paid on each of 908 shares, and £8,570 is considered as paid on the remainder.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since July 19, 1900). Price of silver 28⅛d. per oz. (Sept. 20). Consols (2¾ per cent.) 98⅛—98⅜ for money, 98⅜—98½ for account; 2½ per cent. 97—97¼ (Sept. 20). Stocks and Shares Continuation Days, Sept. 26 and Oct. 10; Ticket Days, Sept. 27 and Oct. 11; Pay Days, Sept. 28 and Oct. 12; Mining Share Carry-over Days, Sept. 25 and Oct. 9.

BRITISH ELECTRIC WORKS CO. (LTD.)—The first annual meeting of this company was held on the 11th inst., when the following report of the directors to June 30 was presented. The accounts covered a period of 16½ months, as the company had to take over the works and business from Feb. 15, 1899, but the company's beneficial occupation did not commence until May 11, 1899, and it was some months before they could be said to be in working order, after the almost entire cessation of business during a long period. The company had to embark upon a new line of business, to get out new patterns and tools for it, to organise the departments, employ travellers and agents, advertise largely, and incur other expenses incidental to working up a new connection. The profit from the trading account (£6,482. 13s. 11d.) had thus been absorbed in the larger expenditure for these purposes. As the plant with which the factory was equipped was largely adapted for the production of cycle parts it was decided to continue this branch of work while the company's business was being established in other directions. The past year, however, was a very bad one in the cycle trade, and the directors have now entirely given it up, and are disposing of the whole of the cycle stock. The directors have succeeded in establishing a new and very satisfactory class of business in the manufacture of ammunition for Her Majesty's Government. Large contracts for this have been taken, and are now being executed. Steady progress is being made in the electrical business, but it was found that it was no use, commercially, for the company to have only two or three new and improved articles for sale, but that they must be ready to supply all that an ordinary

Digitized by Google

customer would be likely to require. This again has meant delay and expense in preparing patterns and producing satisfactory samples, which has now been done. The directors considered it desirable for the company to manufacture its own porcelain for electrical fittings, and accordingly purchased works at Hanley, which are proving a valuable adjunct to the Birmingeam works. The manufacture of a new electricity meter has been undertaken by the company on advantageous lines, which the directors expect will prove a large and profitable business. The orders on hand amount to over £50,000, and if it had been possible to get the preparations for the Government work completed sooner, the accounts would have shown a much better result.

GENERAL ELECTRIC CO. (U.S.A.)—A quarterly dividend of 2 per cent. on the common stock has been declared.

KIDDERMINSTER AND DISTRICT ELECTRIC LIGHTING AND TRACTION CO. (LTD.)—An extraordinary meeting of this company will be held on 21st inst. to approve the Kidderminster and Bewdley light railway order.

MERSEY RAILWAY CO.—In the report just issued the directors regret that the result of the working for the past half-year shows no substantial improvement, the working expenses having reached 77·97 per cent. of the receipts, against 76·67 for the corresponding period last year. Last Session the company obtained powers to adopt electric traction, and to raise the necessary capital for providing the generating plant, &c.

MIRRLEES-WATSON CO. (LTD.)—This company (formerly the Mirrlees, Watson and Yaryan Co., Ltd.) has presented a petition to the Court of Session for an order confirming resolutions reducing the capital from £500,000 to £125,000.

STOCK EXCHANGE NOTICE. — The Stock Exchange committee has been asked to allow 125,000 ordinary £1 fully-paid shares (Nos. 1 to 125,000) of the *Aron Electricity Meter (Ltd.)* to be quoted in the Official List.

VERA CRUZ (MEXICO) RAILWAYS (LTD.)—This is the name of a company inviting subscriptions to a share capital of £750,000. Sir Weetman D. Pearson, Bart., M.P. (president of the well-known firm of contractors—S. Pearson & Son, of Westminster) is chairman of the company, which acquires, in addition to a number of railway lines, the tramways of Vera Cruz, 12 miles in length, at present worked by animal traction. It is proposed to construct about 4 miles of extension lines and to introduce electric traction and an accelerated service. A new concession of the tramways for 99 years has been secured by the company.

WILLANS AND ROBINSON (LTD.)—The registers of transfers and members of this company are closed from 19th inst to Oct. 3 inclusive.

NOTES.

ON another page of this issue will be found an abstract of a Paper upon "Electric Furnaces," read by M. KELLER before the Congress of Electricians recently held in Paris. His Paper does not contain anything strikingly new, but it is a useful summary of recent progress in this branch of electrical science, and as an appendix to the works of MOISSAN and BORCHERS upon the same subject it will be of value for reference purposes. For this reason we have given a copious abstract of the Paper. M. KELLER, being a Frenchman, naturally claims for MOISSAN an important place in connection with the development of the electric furnace, but we think he is incorrect in putting forward the Moissan laboratory furnace as a type from which forms now in use for industrial purposes have been derived. MOISSAN carried out his most valuable and classical laboratory researches upon high-temperature reactions in the years 1893 and 1894, and it is only just to point out that SIEMENS had devised and experimented with an electric-arc furnace 15 years earlier—namely, in 1878–79,—and that the Cowles furnace was used upon an industrial scale in America in 1885, and in this country one year later. These two furnaces, the Siemens and the Cowles, are, therefore, the original types upon which all later forms of arc and resistance furnaces have been based. M. KELLER, in pressing MOISSAN's claims to be the inventor of a furnace which others have copied and turned to industrial uses, is therefore claiming for the latter a position which we are disposed to think the noted French chemist would hardly claim for himself.

IT is interesting to note that, although arc-heating is still employed in many carbide works, furnaces using this method of heating are condemned, since they produce an unnecessarily high temperature and lead to loss of raw materials, and to decomposition of carbide already formed. Resistance heating as applied in the Heroult or Cowles type of furnace is therefore recommended for carbide manufacture and similar purposes, and polyphase currents are advised because the dynamos producing these are more simple in construction and less liable to damage through sudden changes in load than continuous-current generators.

M. KELLER closes his Paper by stating that 230,000 H.P. are now employed industrially in manufactures dependent upon the use of the electric furnace, and that over one-fourth of this total is accounted for by the French carbide industry. We are inclined to consider both these totals too high, if they refer to the average power employed. Reliable estimates in our possession show a much lower total; but doubtless M. KELLER's figures represent the power which is *available* in all the works for electro-thermal purposes during the springtime of the year, when the rivers everywhere are in flood. We know that at other periods of the year, especially in France, the power available for electro-chemical and electro-metallurgical operations is greatly diminished, and the carbide industry is also subjected to a further cause of disturbance owing to the fluctuating demand for the manufactured product. It is satisfactory to learn that the yield of carbide per kilowatt day of 24 hours in the latest form of furnace has been increased to 6·2kg. The theoretical yield is fixed, however, by some authorities at 10kg. The thermal efficiency of the best type of furnace is therefore only 62 per cent., and a wide margin exists for further improvements in design and operation.

THOSE disciples of RUSKIN who collectively form the Ruskin Union, in congress assembled, have recently taken upon themselves to denounce "light railways and electric traction," believing themselves to be "acting in harmony with Mr. RUSKIN's life-long endeavour to keep Lake-land in a pure

Digitized by Google

and wholesome condition for the recreation and enjoyment of the whole nation." The Windermere scheme just abandoned by the British Electric Traction Co. furnished them with their text and pretext. We totally dissent from their denunciation, believing it to be quite out of harmony with the spirit of Mr. RUSKIN'S own writings. Let the æsthetic objectors to the scream of the steam locomotive and the begriming smoke of its furnace rather welcome than condemn a system of traction that is silent and cleanly, and one that withal causes less offence to the eye than innumerable other necessaries of material civilisation. If the "whole nation," or any considerable part of it, is to enjoy Lake-land, as these hysterical clamourers profess to desire, must there not be railways of some sort to convey it thither and bring it home again? And what can better meet the case than the despised "light railways and electric traction."

NOT the Artist but the "Egoist" is the master of these selfish persons, who seek to disguise their anxiety to keep back the crowd under a cloak of affected horror at the prospect of natural beauty being desecrated. To quote from another of MEREDITH'S works: "The courtship of solitude wanes when we are haunted by a second person in pursuit of it; he is discolouring matter in our pure crystal cup. Such is the worship of the picturesque." And such, too, is the secret of much of the local opposition to the introduction of "light railways and electric traction" into picturesque rural districts.

The Times of the 22nd inst. prints an article "from a correspondent," on the well-nigh threadbare topic of the "Comparative Electrical Development in Great Britain and America." We are told therein that there are only 800 miles of electric street railways in the United Kingdom, while in the United States no less than 18,000 miles have been constructed. Bald statements of this sort ignore the relative dimensions of the two territories: there is not room for 18,000 miles of tramways in the United Kingdom. Better far than making gloomy and misleading contrasts, would it be to note the fact that—however belated—electric traction is making remarkably rapid headway in this country, and there are indications that in the next few years the mileage of electric lines will have increased tenfold, if not more.

ON one point, however, we are in harmony with the writer in *The Times*. Quoting from the report of Mr. MARSHAL HALSTEAD, American Consul at Birmingham, he casts ridicule on the widespread tendency of British local authorities to make separate experiments for each town, instead of relying immediately on the experience gained in other places. "Birmingham cares nothing for the newly-acquired tramway experience of Liverpool"; "Glasgow sent a commission to study the street car systems of the cities of the United States, Germany, France and Austria-Hungary, and . . . built merely an experimental line." In the truly experimental days of electric traction this sort of thing was justifiable, apart from the pleasant holiday it afforded the peripatetic deputations; but nowadays, to look outside the United Kingdom for examples of electric tramway traction is as unnecessary and absurd as to send a municipal deputation round the globe before deciding upon the architecture for a town hall, or the construction of waterworks. In quality if not quantity of electric traction, Great Britain takes the lead.

THE first instance, we believe, of a judicial restrainer from the use of a telephone occurred recently in the United States. A time may come when English Courts will adopt a similar form of injunction. In the American example, a man persisted in making love to a pretty dressmaker, greatly to her annoyance, by ringing her up ten or twelve times a day. He was promptly estopped by the judge. An American contemporary observes that this case emphasises the necessity for some better means of safeguarding telephone subscribers against intrusive callers. At present a telephone is a dead earth in the insulation of one's privacy—unless, indeed, the drastic practice be adopted of removing the receiver and so becoming deaf to the entire telephone world.

Telephone between London and Brussels.—It is announced that direct telephonic communication will be established between London and Brussels at the beginning of next year at the charge of 10fr. for three minutes' conversation.

Central London Railway.—The Bond-street station of this railway was opened for traffic on Monday last. Owing to delay in completing the lifts equipment, this station had remained closed for several weeks after the opening of the line.

Incorporated Association of Municipal and County Engineers.—At Tonbridge, on Friday, the 20th inst., a "Home District Meeting" of this Association was inaugurated. Among the Papers read was one on "Electricity Supply for Lighting, Power and Tramways, with Special Reference to Small Towns," by Mr. H. L. P. Boot, of Tunbridge Wells.

Central Technical College Old Students' Association.—The third annual dinner of the Association of Old Students of the Central Technical College will be held on Tuesday, October 2, at the Restaurant Frascati, Oxford-street, W. Old students can obtain further particulars from the honorary secretary, Mr. M. Solomon, 12, Edith-road, West Kensington, W., to whom all applications for tickets should be made

Cable Interruptions:—

	Date of Interruption.
Latakia—Cyprus	June 21, 1899
Tangier—Tarifa	Jan. 5, 1900
Ceara—Maranham	Feb. 20, 1900
Pará—Maranham	Mar. 2, 1900
Môle-St. Nicolas—Cap Haitien	Mar. 7, 1900
Pernambuco—Para	Sept. 19, 1900
Zanzibar—Mombasa	Sept. 20, 1900

Errata.—In the description of the switchboard gear in the Port Dundas works at Glasgow, published in our last issue, it should have been stated that five of the feeder panels were made by the Holland House Co., and one by Messrs. James White, instead of three by each firm.——The last line of our report of the Paris International Electricity Congress in the same issue should read, "apparatus based on the electrical properties of selenium."

City and South London Railway.—About half-past six on Wednesday night an accident occurred on the City and South London Railway, between the Bank and London Bridge stations. According to the official report, a train, the engine of which had broken down, was run into by a second train. The impact was not great, and no passengers complained of injuries. Traffic, however, was a good deal disorganised, and for a considerable time the trains between Moorgate-street and London Bridge stations had to be run on a single line.

Digitized by Google

The full service between London Bridge and Clapham was uninterrupted.

Utilisation of Waste Heat.—According to a consular report, the three large German electrical companies, Messrs. Siemens and Halske, the Union, and the Allgemeine Electricitäts Gesellschaft, have founded a company bearing the title "Abwarme Kraftmaschinen Gesellschaft" for the exploitation of patents to utilise the waste heat of exhaust steam and condensing water. The report states that should the invention fulfil the expectations of its projectors, especially with regard to machines of large dimensions now in course of construction, "it will lead to a most important, in fact epoch-making, progress in the economy of central power plants."

Para-Pernambuco-Monte Video Cable.—In connection with the laying of an additional cable by the Western Telegraph Co. from Para to Monte Video, the section from Para to Pernambuco (1,230 knots) was laid some time ago, and the Telegraph Construction and Maintenance Co.'s cable ship "Scotia" is due on October 10 from Rio de Janeiro after laying the second section from Pernambuco to Rio de Janeiro (1,867 knots). The same vessel goes out later with the remaining section from Rio to Maldonado and Monte Video (1,250 knots). This will complete the third cable of the Western Company on this route, the line being in duplicate from Para to Pernambuco, and in triplicate from Pernambuco to Monte Video.

Personal.—Mr. L. B. Stillwell, electrical director of the Niagara Falls Power Co., has resigned his position with that company and removes to New York, where he will open an office as consulting electrical engineer. Mr. Stillwell has been connected with the Niagara Falls Power Co. practically since its inception. For the past two years Mr. Stillwell has given a large part of his attention to consulting work for other electrical enterprises, notably the equipment of the elevated railway of the Manhattan Railway Co. in New York. Following Mr. Stillwell's departure from Niagara, Mr. Philip P. Barton and Mr. Paul M. Lincoln, assistant superintendents, have been promoted, Mr. Barton having been appointed superintendent of the operating department of the Power Company, and Mr. Lincoln resident electrician.

Carbon Filaments and Lightning Flashes.—A correspondent in Madison, Wis., U.S., who has apparently forgotten to append his signature, sends us the following interesting comments on this subject:—

Your editorial note in the issue of *The Electrician*, dated August 31st, upon the phenomenon observed by the electric lighting people at Calcutta when the region is visited by thunderstorms, recalls similar experiences which have been very common in the region of our plains lying east of the Rocky Mountains. In this region, thunderstorms are very severe and quite frequent, and the disturbance of the lamps, which is mentioned in your editorial note, is quite common. The brightening of the lamps may sometimes be so great as to break the filaments. The phenomenon does not wholly consist in the brightening of the lamps, but the dimming of their incandescence is equally evident.

I have always ascribed the phenomenon to the flow of the induced electric charges which gather upon overhead wires and are discharged therefrom during the various cycles of condition of the clouds overhead. When one of the conductors is grounded or for other reasons makes the most convenient path for the flow of the induced charge during its accumulation or its discharge, a current may naturally be expected to pass through the lamps from the other conductors of the systems into this convenient conductor.

The amount of current which will flow on to and then discharge off of a partially-grounded system during the passage of a heavy thunder cloud overhead is quite enormous, as is shown by the heating effect of the current flowing to the ground; and it is of ample magnitude to make a considerable disturbance of the brilliancy of the lamps when the overhead circuits cover an extensive area.

Failures of Automatic Block Signals due to Lightning.—Mr. H. D. Miles read an interesting Paper on this subject before the Railway Signalling Club at Atlantic City (N. J.) on September 11. There were, he said, two kinds of failures of automatic signals due to lightning, the failure of signals to clear, and the consequent delay to traffic; and the failure of signals to go to danger, and the consequent imperilling of train movements. The introduction of the carbon contact for relays and their use in combination with fuse wires had solved the first problem. A lightning arrester which would take care of the heavy discharges without opening the circuit, combined with the use of carbon to prevent the fusing of relay contacts by so much of the lightning current as might pass through the arrester, were apparently the devices which must be employed to solve the second problem. He believed that it was too early to say that the solution of the latter had been accomplished; nevertheless, the service rendered by the choke-coil lightning arrester encouraged the belief that it or some better device would accomplish what was desired. The fuse wire was the chief agency of their present woes, and until it was dispensed with the block signal maintainer was sure of an abundance of calls during the lightning season. The only utility of fuse wires where carbon contacts were employed was to protect the relays and signal instruments from the heavy lightning currents; if these could be diverted to the ground before reaching the instruments, the problem would be solved. The first arrester used by the Michigan Central Railroad to prevent the fusing of contacts and the burning of magnet coils was the old style saw-teeth type, the ground plate being connected with the relay wires which led to the rails of the track. The lightning currents which fused the relay points did so on account of the path afforded through the track relay, track wires and rails to ground, and as the air-gap between the contact strips and ground plate of the arrester was less than that between the armature and magnet coils of the track relay, it was naturally inferred that high-potential currents would take the path of least resistance, and thus avoid fusing the contact springs. The service rendered by this form of arrester, even when combined with fuse wire protection, did not prevent the fusing of platinum contact points, and consequently these arresters were abandoned in 1898, and carbon contact strips and ground plate arresters having a high resistance substance for making contact between the ground plate and the contact strips, which were connected to the track and line wires, were substituted. One-ampere fuse wires for track and 2-ampere fuse wires for line circuits were used in connection with these arresters. The ground plates in this case were connected with galvanised iron pipe driven in the ground, experience having proved that the use of the rails as grounds increased the number of signal failures. To guard further against the danger of fused points, carbon points were used in relays to control all line circuits, and the Buchanan back-contact shunt was applied where track circuits were controlled in order to shunt the track battery should the front contact fuse. It was considered impracticable at that time to use contact points made of carbon for controlling the low potential track currents, on account of the high resistance of that substance. Since these alterations were made there had not been a single case of a signal being held clear by fused contacts, although many instances had occurred of the signals being held at danger on account of blown fuse wires. From January 1 to August 20, 1900, 36 per cent. of the failures of signals to clear were caused by lightning, and nearly all of these failures were due to blown fuse wires. In 1899, 5 miles of the semaphore type of automatic signals were installed, carbon contacts being used to control all circuits, and 2½-ampere fuse wires and choke-coil lightning arresters being used in all line circuits, no safeguards other than carbon contacts being provided for the track circuits. In this instance, the arresters, instead of being in the relay boxes, were located in cast-iron boxes on the telegraph poles. Two types of choke coils and arresters were employed. In one, the coil of wire was wound on a hard rubber spool or cylinder, in the other the wire was wound on a porcelain spool having a hollow centre in which was inserted a soft iron core. On this latter section of blocking, no signal failures had occurred due to lightning, although lightning troubles had been experienced both east and west of this section of blocking, and the porcelain spools of three of the arresters had been shattered by lightning. It was too soon to judge of the efficiency of this method of protection, but as there were line wires throughout each block and several lightning storms had passed over this section, the inference to be drawn encouraged a fair hope for the future.

THE INTERNATIONAL ELECTRICITY CONGRESS.

(*Continued from page 822.*)

Section II.—*Sub-section A.—Production and Mechanical Utilisation of Electricity.*

On Monday, Aug. 20, M. Bède, of Brussels, explained the tramway contact system which is under experiment in that city. The contact pieces pass through a rubber stopper, which serves at the same time as an insulating cover for the conduit, containing the conductor and as a spring to break the circuit as soon as the collector leaves the contact knob. The main cable is placed in the iron conduit parallel to the rails and separated by a slot 28mm. wide from one of them. The current collected on the car passes through this slot. At Brussels there are holes in this conduit every metre, and these are closed by the rubber stoppers mentioned. Below each of these the cable is bared, and copper saddles are connected to it. These terminate 3mm. below the bottom of the contact piece passing through the rubber. The pressure of the collector upon these contacts pushes them down against the copper saddles, and thus makes a connection between the car and the line. Good results had been obtained with this system.

M. Rey, of the firm of Sautter, Harlé & Co., then read a Paper relating how the method of predetermining the fall of potential in polyphase alternators by means of M. Blondel's "theory of two reactions" had proved most accurate in the case of a special alternator constructed by his firm. He also read a note on the "Compounding of Alternators," by M. A. Blondel, who was prevented through illness from being present himself. The system proposed by M. Blondel was to employ a continuous-current exciter whose armature is traversed by the polyphase current of the alternator itself or from a transformer in series with the main circuit of the alternator.

M. Thury spoke on the application of boosters to the automatic regulation of the E.M.F. of accumulators. M. Thury's method, which he considers of special utility in the case of so called buffer batteries in tramway power stations, is to employ an auxiliary dynamo whose field can be reversed between two limits passing gradually through zero. The difficulty due to sparking at the commutator is overcome by using machines with short armatures provided with smooth windings, and large air-gaps, and by increasing the number of poles. The automatic regulation can be facilitated by means of a compound winding, and then the reversal of polarity is more rapid.

On the Tuesday Dr. Silvanus P. Thompson read his Paper (written in French) on "Electromagnetic Mechanisms." He stated the general principle that in every electro-magnetic system, whatever the configuration traversed by an electric current, there are always mechanical forces tending to change the configuration in a manner to render the magnetic flux a maximum. This principle could be stated in a number of different ways. For instance, that the mechanism moved so as to reduce the reluctance or magnetic resistance to a minimum; that it moved in such a manner as to make the magnetising windings embrace as many lines of magnetic force as possible; or, again, that the tendency was to increase the product of the current and the magnetic flux with which it is interlaced. This latter way of putting it may be expressed by the formula

$$f = \mathrm{IS}\,(\Psi_1 - \Psi_0)/l,$$

where I is the current in the conductor, S the number of turns, l the relative displacement of the members of the mechanism, f the mean force exerted between them, and the expression in the bracket the increase in magnetic flux. This may be stated more generally $f = \mathrm{I}\frac{d\Psi}{dx}$, f being now the force tending to produce displacement per winding of the circuit.

While the magnetic circuit always tends to improve itself, the circuit of the current has, on the other had, a tendency to extend so as to take up as much room as possible. The two phenomena follow from the same principle, as the electric circuit, by enlarging, increases the section of the magnetic circuit in the ambient medium and, in consequence, the value of the flux. Dr. Thompson also pointed out that, as the potential energy of the system always tends towards a minimum value and the tendency of masses of iron is to move in such a way as to magnetise themselves as much as possible, it follows that a mass of magnetised iron possesses less potential energy than the same mass not magnetised. Consequently the specific heat of magnetisation must have a negative value. The author also alluded to an apparent paradox in the behaviour of a coil and plunger. It is well known that the plunger, if left to itself, takes up a central position in the coil, its two ends projecting to an equal extent at each end, as in this way the magnetic resistance of the circuit is at its minimum. If, however, the length of the plunger is reduced to a limiting value, and a small iron sphere is employed to explore the interior of the coil, it is found that there is no force either in the interior or exterior, but merely at the point where the ball ends or leaves the coil, because it is at this point that $d\Psi/dx$ has a maximum value. Dr. Thompson concluded his review of the present state of this branch of electro-technics by giving a classified list of electromagnetic mechanisms, the list being an extension of the one given in his book on "The Electromagnet."

M. Boucherot then read a Paper, by M. Maurice Leblanc, on the design of dynamo electric machines. M. Leblanc's Paper puts forward some new views of considerable importance, and we shall deal with it fully in a subsequent issue. The next paper was by M. Ernest Gérard, engineer-in-chief of the Belgian State Railways. He had chosen for his subject the tractive resistances of motor cars on rails. The formula customarily employed to give the resistance in tons is of the form

$$r = a + b\mathrm{V} + \frac{c\mathrm{SV}^2}{\mathrm{T}} \pm m,$$

where a, b and c are co-efficients, V is the speed in kilometres per hour, m the gradient in millimetres per metre, S the adhesion surface of the train, and T the weight of the train in tons. For trains pulled by locomotives at speeds less than 60km. per hour, the V^2 term can be neglected and the first two terms only employed. Thus the formula used by the engineers on the Eastern Railway of France reduces to $r = 1{\cdot}80 + 0{\cdot}08\mathrm{V}$, which gives a sufficient approximation. In the case of single cars, however, even at the low speeds of 30km. and 40km. per hour, the air resistance plays an important part. M. L'Hoest had made experiments on the Belgian State Railways with motor cars, and had arrived at the following formula for them:—

$$r = 1{\cdot}80 + 0{\cdot}04\mathrm{V} + \frac{0{\cdot}0415}{\mathrm{T}}\mathrm{V}_2 \pm m.$$

As the item involving V^2 no longer includes the factor S, the formula is easy of application.

M. Blondin then described the surface-contact system of traction recently devised by M. Dolter, which is being experimented with on a line at Porte Maillot 750 metres long. This system, which is, in a way, the converse of the Pollok-Binswanger system, has a rubbing contact, which is either magnetised normally by the current which feeds the motors or in certain cases by the current from a small battery of accumulators placed in the car. In passing over a knob, this collector attracts an iron cylinder, forming one arm of a crank lever, and the other arm of this lever connects two carbon contacts, one of which is connected to the feeder and the other to the knob.

On Wednesday Signor Semenza described briefly the Paderno-Milan power transmission plant, a full account of which has already appeared in *The Electrician*, and also gave some account of the working of the system since it was opened. M. Boucherot then read a Paper on the compounding of alternators, describing his compounding exciter exhibited at the exhibition in connection with a Bréguet alternator. M. Thury followed with a Paper on power transmission with high-pressure continuous current. He admitted that transmission by means of polyphase alternating currents was advantageous in most cases when the distance was not too great and when the line pressure could be directly generated by the dynamos. This latter condition limited the pressure to 15,000 volts at the

Digitized by Google

present day for dynamos of a higher capacity than 800kw., and possibly a limit of 20,000 volts might soon be reached; but by coupling series-wound continuous-current machines in series and insulating the machines themselves much higher pressures could be attained. A continuous-current machine could, he said, be sufficiently insulated for 3,600 volts, and by employing ten 1,000 H.P. units each consisting of an engine driving two 3,000-volt generators, a total pressure of 60,000 volts with a current of 115 amperes could be produced and transmitted economically for more than 200km. The chief difficulty of this system was in the motors, for when smaller than 100 H.P. they spark considerably at light loads. This difficulty had been overcome by regulating at the same time by adjusting the field and by rotating the brushes.

On Thursday, the first Paper before this sub-section was one by M. Routin on "Compound Alternators and Stationary Transformers." One of these machines is described by our Paris Exhibition correspondent in another part of this issue, and M. Routin dealt with some types of machines built more or less with the same object. Col. Renard then made some remarks on the Paper read by M. Ernest Gérard on Tuesday, pointing out that the formula given as the results of the Belgian experiments agreed remarkably with general data regarding air resistance. He also gave some figures to show the importance of the design of the front and back of vehicles for rapid transit, on account of air resistance. Thursday's proceedings were terminated with a Paper by M. Claude on electrolysis by return tramway currents, and one by M. Léon Gérard descriptive of a three-phase system for towing boats, employed between Brussels and Charleroi, which is combined with a light and power distribution network.

On Friday M. Janet gave an account of some experiments made on an "Alioth" 15kw. rotatory converter at the Central Laboratory of Electricity. M. Janet's experiments demonstrated that there was an undulation of the pressure recovered at the brushes, and also showed the influence of the excitation on the continuous current collected at the brushes while the alternating current remained constant.

M. Lombardi then read a Paper on the employment of condensers for high pressures. He gave results of experiments made, utilising pure paraffin and ceresin for the insulating plates. One of these condensers, with a capacity of 1mf., or ½mf. at 10,000 volts, was exhibited at the exhibition. The dissipation of energy, he said, hardly exceeded 1 per cent., so that the temperature did not increase appreciably. Such plates had been tested to 17,000 volts. The price of these condensers might be as low as 50fr. per kilovolt-ampere. M. Boucherot regretted the bad reputation the condensers had acquired. An experiment was to be made, however, by the firm of Buquet of a system of series distribution with condensers and induction-coils, for public lighting in the village of Noisiel. He then spoke of a "thermo-electric chain," which it had occurred to him to test as a phase-shifter for an alternating circuit instead of a capacity. If a continuous current is passed for a certain time through a copper-iron-copper couple, and if the circuit be broken and the double couple connected to a galvanometer, a current similar to the discharge of a condenser will be observed. To try the effect of a similar device in an alternating circuit, two or three hundred iron and copper washers soldered alternately were introduced into the secondary circuit of a transformer, which gives less than one volt, and measurements were made on the 100-volt primary; but it was not possible to observe any appreciable effect. He then intended to repeat the experiment with several thousands of copper and iron washers, but he interrupted this research on finding that the theoretical shifting of phase would be $\pi/4$ and not $\pi/2$, and on taking account of the Joule effect it would be even less than $\pi/4$. M. Leblanc agreed with previous speakers that troublesome increases of voltage with condensers might be done away with by increasing the capacity of the condensers. Increases of voltage, damaging although so instantaneous as not to be measurable with ordinary apparatus, were caused by harmonics which reinforced the condensers; but he thought this could be avoided by a proper arrangement of holes in the coil discs of the dynamos. M. Leblanc also suggested a system of single-phase alternators connected in series, which, he considered, had all the advantages of the series continuous current system without some of its disadvantages.

Section II.—*Sub-section B.—Electric Lighting.*

On Monday, August 20, M. Laporte read an abstract of a Paper by M. Blondel, on progress in electric lamps. This Paper included a most excellent summary of recent work, and we shall publish an abstract of it in a future issue. The discussion was continued at intervals during Monday, Tuesday and Wednesday. M. Hippolyte Fontaine, who presided, mentioned some lamps of the Gramme motor type which had been working very well for 20 years in foundries, in spite of the dust, and he attributed this to the power of the motor. M. Mailloux spoke on American practice, and said that clockwork arc lamp mechanisms were being replaced to a large extent in the United States by simple clutch movements. In America, high pressure had been employed for arcs. They had begun at 70 volts, and had risen as high as 125 volts, and lamps with long arcs even up to 160 volts and 180 volts had been employod for connecting directly on to 230-volt and 240-volt circuits. These lamps, however, gave a very violet light. He thought there was no future for these high-pressure lamps as they were wanting in efficiency, life and light. M. de Fodor suggested that the reason we were more particular in Europe than they were in America as to the steadiness of arc lamps, was because in the latter country there was practically no competition by the incandescent gas burner. M. Bochet took exception to M. Blondel's statement that differential arc lamps cause an economy of nearly 15 per cent. He was convinced that shunt lamps with a good regulating mechanism were as efficient as differential ones. Prof. Ayrton referred to the Langhans incandescent lamps, whose filaments were made of a compound of carbon and silicon. He had tested 100-volt lamps with an efficiency of 1·13 watts to 1·7 watts per candle, but unfortunately he did not know what was the life of these lamps. The discussion extended to the 100-volt *v.* 200-volt question, and it was also relieved by a discussion on tariff systems, started by M. de Fodor, and a Paper by M. Weissmann on low-pressure incandescent lamps with thick filaments.

The most important Paper read before this section was that of Mrs. Ayrton on the continuous current electric arc, which she read in French on Thursday. From curves shown by Prof. Ayrton at Chicago in 1893 it could be seen that the candle-power of the arc increased with the length of the arc up to a certain point, and then diminished, and there was a definite maximum point on the curve for each particular current. On making other observations in this direction, a distinct minimum and a second maximum were detected. In her present Paper Mrs. Ayrton offers an ingenious explanation of this remarkable effect. The cause of the first maximum and minimum is, by her hypothesis, the varying obstruction of light by the negative carbon, which carbon acquires a sort of supplementary point for short lengths of arc. The second maximum is occasioned by the increase in the light-absorbing properties of the mist formed by condensed carbon in the so-called gaseous part of the arc. One conclusion in her Paper should have an important practical bearing, for she points out that long arcs are uneconomical, and that the most economical arc should be a short one with large currents, although not so short as to produce hissing. We hope to publish a translation of the Paper in an early issue. In the discussion on it, M. Bochet recalled the fact that M. Blondel attributed the reduction of the intrinsic luminosity of the crater with the candle-power to the cooling which takes place when an arc is burning in the open air. M. Arnoux said that it was an important question whether, at the critical or most economical length of arc indicated by Mrs. Ayrton, the arc would be steady. With most carbons employed at present, these lengths of arc would occasion the formation of mushrooms on the negative carbon, which caused considerable unsteadiness in the light. It seemed, therefore, that not only must arc lamp makers construct mechanisms maintaining the length of arc very constant at the critical length, but also that carbon makers must endeavour to furnish carbons on which mushrooms would

Digitized by Google

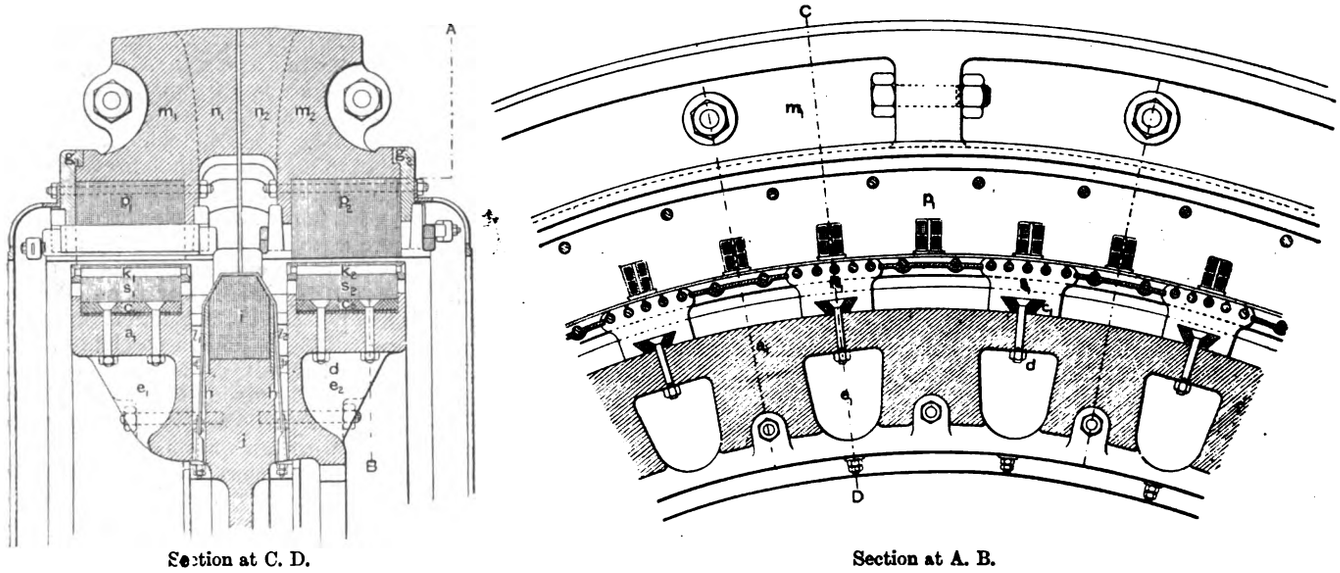
not form under these conditions. M. Fontaine emphasised the remarkable result that Mrs. Ayrton had shown, that the best efficiency would be obtained with arc lengths of about one millimetre. Dr. Silvanus Thompson said that Mrs. Ayrton's communication accounted for two hitherto unexplained phenomena. The first had been pointed out by Mr. A. P. Trotter, that when observing an arc through a slit in a rotating disc one saw something turning. This, Dr. Thompson thought, was probably due to eddies of carbon dust. The other phenomenon was the counter-E.M.F. of the arc, which he thought that the high resistance of the true carbon vapour at the surface of the crater might help to explain. A communication by MM. Blondel and Gigouzo on the subject of alternating current arc was then read and briefly discussed.

(*To be concluded.*)

THE PARIS EXHIBITION.—VII.*

(BY OUR SPECIAL CORRESPONDENT.)

The design of some of the French alternating-current machines is very interesting, and differs frequently in its fundamental principles from that of other countries. Some of these points of difference run the risk of being termed fanciful or capricious, others however, as the Hutin and Leblanc "amortisseur," are undoubtedly inventions of real value.



Section at C. D. Section at A. B.

FIG. 39.—FARCOT TWO-PHASE ALTERNATOR WITH HUTIN AND LEBLANC "AMORTISSEUR."

The boiler plate on the rotating part of the German "Helios" dynamo attracts immediate attention, and suggests other unusual features in the design of the machine, and in the same way the covering-in of the flywheel magnet of the Farcot set with wooden battens, and the gaudy brass guard which protects the ends of its armature windings (see Fig. 38),

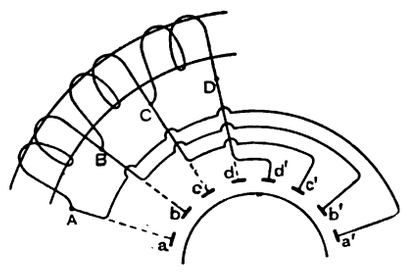


FIG. 40.

hint that there may be other and more important points of originality in this alternator. This impression is correct, for the Farcot machine is fitted with the Hutin and Leblanc amortisseur, and the construction of the armature and field magnets is original in other ways. The dynamo is two-phase, and is designed for an output of 200 amperes in each phase at a pressure of 2,200 volts, a frequency of 42 ∿ per sec., and a power factor of 0·85. Its speed is 78·5 revs. per min. and there are 82 polar projections at each side of the field magnet wheel.

In one respect the field magnets resemble those of the Mordey alternator. Instead of the now usual ring of poles, wound so as to present alternate polarity to the armature, the rotating field magnet consists of a central magnetising coil (*i* in Fig. 39) wound round the rim of the flywheel *j*, and two cast-iron rings a_1a_2 of the section shown in the left-hand view in Fig. 39, and carrying the laminated polar projections s_1 and s_2. The castings a_1 and a_2 are each in four segments. To fasten the pole pieces to the rim of the flywheel, keys c_1c_2 of swallow-tail section are fitted in to the bottom of the packets of discs, and held by bolts *d*, passing through the rim of the wheel, and secured by nuts in the niches e_1e_2. The magnetising coil is supported between the two cheeks l_1l_2 which also carry vanes to ventilate the coil and pole pieces, and the stirrups *h*, placed at intervals, help to hold the coil in place. There are 460 turns of wire 7·5mm. diameter on the coil. Its resistance is 3·5 ohms, and it carries a current of 50 amperes at full load. The total weight of the field magnet without its shaft is 50 tons, of which three only represent the winding. The woodwork on each side of the flywheel is to diminish air friction. The battens are of mahogany, and are placed radially.

The armature or stator of the machine is held in a frame composed of two circular castings m_1m_2. It carries the core discs p_1p_2, which are clamped between the cast-iron segments g_1 and g_2. The two vertical parts of the armature serve each for one phase, and where they are juxtaposed the castings m_1m_2 have projections n_1n_2 whose number is the same as that of the armature coils—viz., 64. The intervals between these projections allow for the efficient ventilation of the field magnet. Each of the two armature rings is therefore wound with 64 coils as an ordinary single-phase circuit. The coils have each ten turns, and are connected in series. As is seen in the illustration, the coils are wound in two layers (of five turns each) and are placed in wide slots in the armature core. They are insulated by micanite tubes, and between the two

* Previous articles appeared in *The Electrician* of July 20 and 27, August 3, 24, and 31, and Sept. 14.

Digitized by Google

coils in each slot is a triangular block of paraffined wood. The section of the copper ribbon of the coils is 8·5 × 88mm., and the resistance hot of each coil is 0·113 ohms. The two armature windings are staggered, that is to say, the slots in one are facing the middle of the polar projection of the other. To enable the two parts of the armatures to be taken apart easily, a distance of a few millimetres is left between the projections n_1 and n_2, for otherwise remanent magnetism would cause them to cling together. The following are the main dimensions of the stator: External diameter of the armature 6 80 metres, internal diameter of the armature 5·515 metres, maximum width of the armature (not including the brass guards) 98cm., width of each armature core 80cm., air-gap 6·5mm., total weight of stator 60 tons.

The "amortisseurs" remain to be described. They consist merely of copper bolts k_1k_2, 28mm. in diameter, and riveted at their two extremities to copper segments. Each pole of the magnet wheel is provided with five of these bolts, and in addition, two similar bolts are riveted to the segments in each of the intervals between the poles, and hold a copper plate which is to prevent the humming of the alternator. The principle of the amotisseur, or "damping coil" was explained in *The Electrician* in 1896 (Vol. XXXVIII., p. 210), when one of the first machines constructed with it was described. The division of the armature into two parts, with one winding on each, is in order to obtain the full effect of this device, both as a means of diminishing armature reaction and facilitating parallel running. Although nowadays alternators constructed on ordinary lines run in parallel without difficulty, the latter function of the damping coils is by no means unimportant in this machine, which is driven by a single cylinder engine.

In ordinary alternators with polyphase windings, the magnetic flux due to the currents in the armature is a constant rotatory one, rotating at the same velocity as the magnetic flux of the field magnet, and in the same direction. It would not move, therefore, in relation to the damping coils, and would have no effect on them. With an ordinary single-phase winding, however, the flux due to the armature current is an alternating one, and can be conceived as being resolved into two fluxes, revolving with the velocity of synchronism, but in opposite directions. One of these will, as before, have no effect on the amortisseurs, rotating as it does at the same speed as the magnets. The other will move in relation to the magnet wheel and the amortisseurs at twice the speed of synchronism, tending to generate an electromotive force in these damping coils of twice the frequency of the alternator current. The currents thus produced in the damping coils will give rise to magnetomotive forces opposing and neutralising the second component of the magnetic flux induced by the armature reaction as already mentioned.

So much in regard to armature reaction. The explanation of the effect on parallel running is simpler. The damping coils constitute in themselves the armature of an asynchronous motor. When the alternators tend to fall out of phase these circuits react strongly, and the momentary difference in speed is limited to a slight slip of one of the alternators with respect to the other, which allows the machines to come into step again.

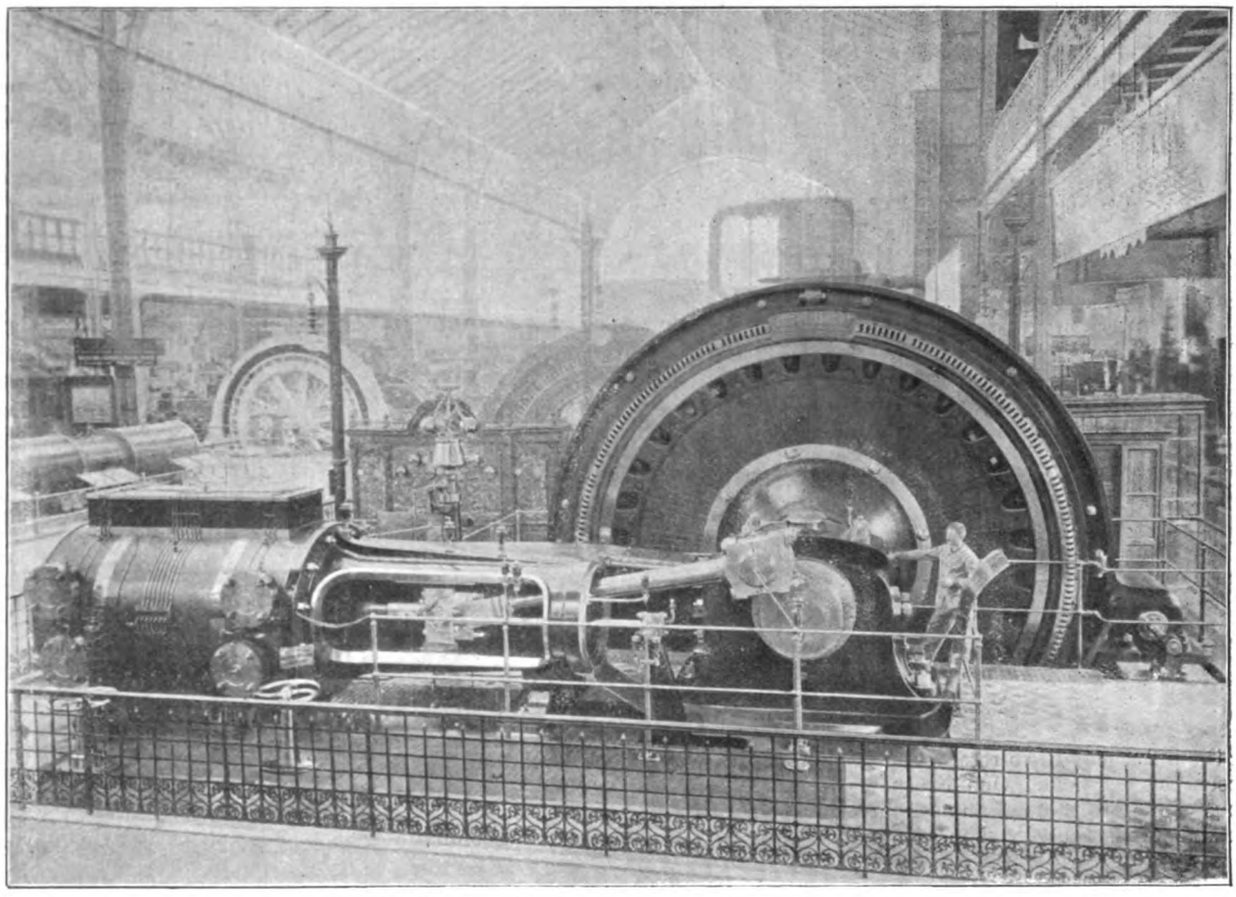

FIG. 39.—GENERAL VIEW OF FARCOT TWO-PHASE ALTERNATOR.

The exciter is fixed at the end of the alternator shaft, and generates a current of 50 amperes at 175 volts.

As already mentioned, the engine is a single-cylinder one. The diameter of the cylinder is 1 metre, the stroke 1·350 metres, and the speed 80 revs. per min. It has four Corliss valves. Running condensing and with a steam pressure of 6kg. per square centimetre, it will develop 700, 1,020, or 1,280 E.H.P., according as the cut-off is at 10, 20, or 30 per cent. of the stroke. As low a steam consumption as 5·8kg. of steam per horse-power-hour is said to have been obtained with similar engines.

At first sight there appears to be nothing more striking about the Grammont three-phase alternator than the bright copper-clad coils of its rotating flywheel magnet. On closer acquaintance, however, one finds that the chief interest attaches to its exciter, which is one of the most remarkable

Digitized by Google

machines in the exhibition. It is wound and connected in such a manner as to compound not itself, but the alternator. This so-called compounding exciter is also the invention of MM. Hutin and Leblanc, and is designed on the following principle. Consider an ordinary continuous-current armature armature, it will be possible to obtain continuous current from fixed brushes when one of the following two equations are fulfilled,

$$n + k = a/\omega,$$
or $$n - k = a/\omega,$$

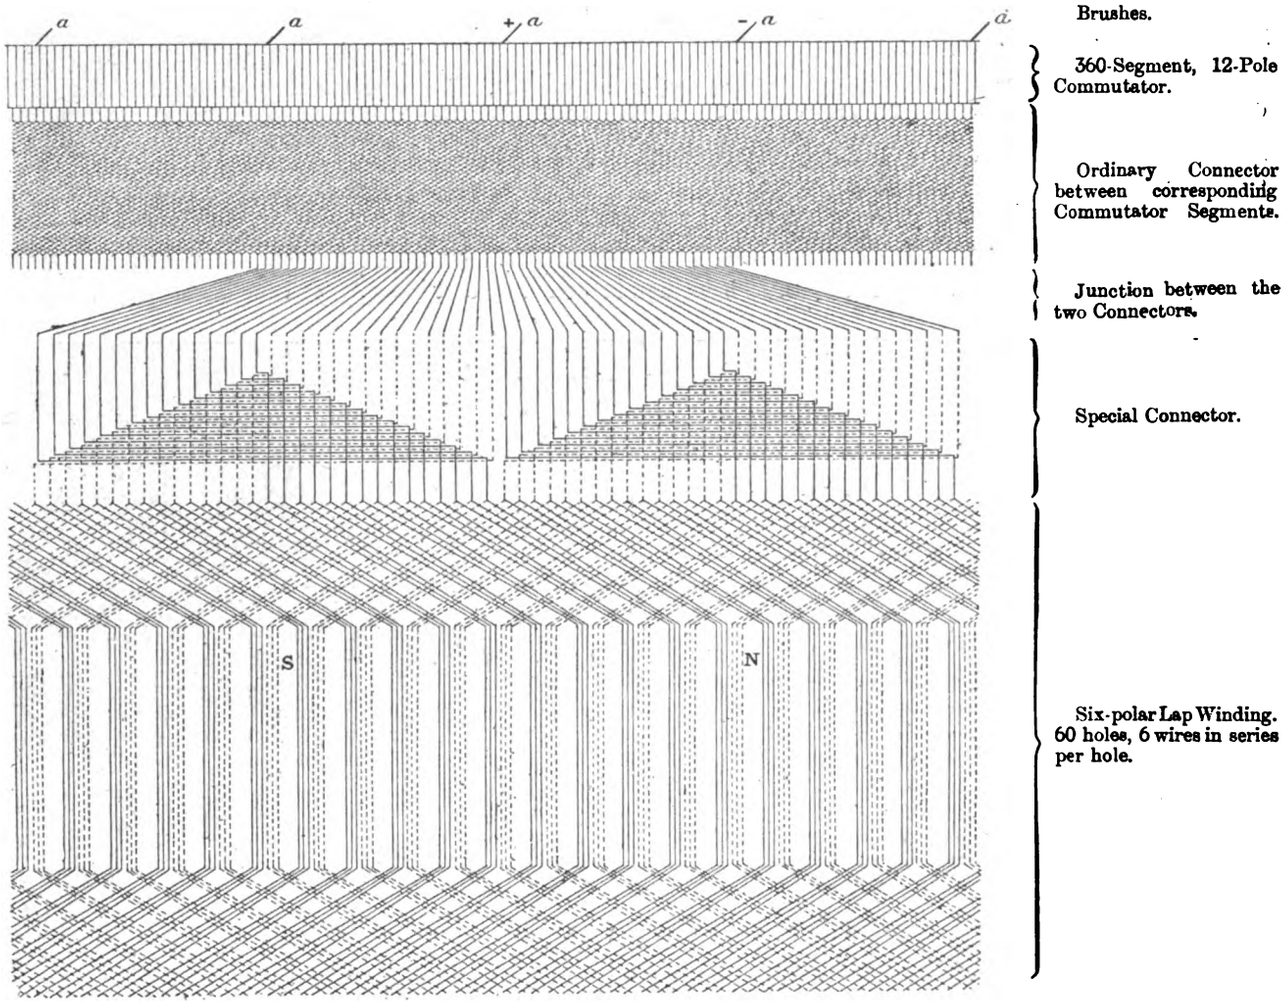

FIG. 41.—PLAN OF WINDING AND ARMATURE CONNECTIONS OF COMPOUNDING EXCITER.

under the influence of two rotatory magnetic fields instead of the usual steady field. One of these fields is excited by windings similar to those of an asynchronous motor connected in parallel with the alternator, and the other by similar windings in series with the alternator armature. Then if there are n pairs of poles for the rotating field, and k pairs of brushes; if a be the frequency of the rotatory alternating current through the field windings, and ω the speed of the according as the armature turns in the direction of the rotating field or in the inverse direction. For this, however, it is necessary that the ordinary connections between the armature coils and commutator be reversed about an axis of symmetry.

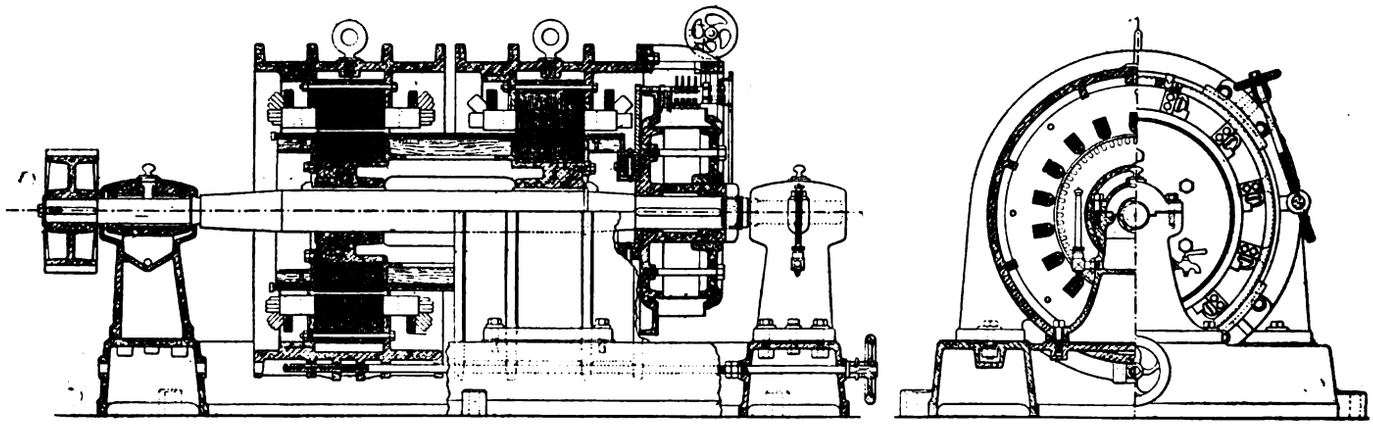

FIG. 42.—COMPOUNDING EXCITER OF GRAMMONT ALTERNATOR.

What is meant by this reversal of connections is shown in Fig. 40 (on p. 844), which for the sake of simplicity is drawn for a two-pole armature. Any diameter (a vertical one in Fig. 40) is taken as axis of symmetry, and instead of connecting A to a, as

Digitized by Google

would be done ordinarily and as is shown by the dotted line, it is connected to a', the corresponding point on the other side of the vertical axis. Similarly B is connected to b' instead of b, and so on. Applying this to a multipolar armature, all that is necessary is to take the set of the windings corresponding to each pole by itself, and then to take in each case an axis of symmetry through the middle point of each of these sections of the armature, and to reverse the connections with respect to this axis.

To obtain the requisite ratio between the number of pairs of brushes, k, and the number of pairs of poles, n, demanded in the above equations, is a simple matter, merely requiring the parallel connection of a greater or less number of corresponding commutator segments. Fig. 41 shows the connections for a machine in which the armature and rotatory field revolve in the same direction, and in which the equation $n+k=a/\omega$ is satisfied by making $n=3$, $k=6$, and $\omega=333$, a being 50. It may be noted that the exciter armature will tend to rotate at a speed a/n, which is greater than ω, so that being geared by a wheel and pinion to the alternator shaft it actually returns work to the engine in assisting it to drive the alternator.

The general arrangement of this exciter is shown in Fig. 42, and Figs. 43 and 44 show the details of the actual connecting pieces between the armature coils and the commutator.

The alternator itself is driven by a single-cylinder horizontal Piguet engine, and is a 600kw. machine. Its whywheel-magnet casting is in two parts, and there are 64 steel poles of circular section with rectangular pole-pieces. Each pole is fastened into a recess in the flywheel rim as seen in Fig. 45. The winding is of copper strip, and the insulation is merely paper, which is sufficient as the coils are all in series and the difference of potential between adjacent windings only 0·02 volt. At the other end of the coil, facing the armature,

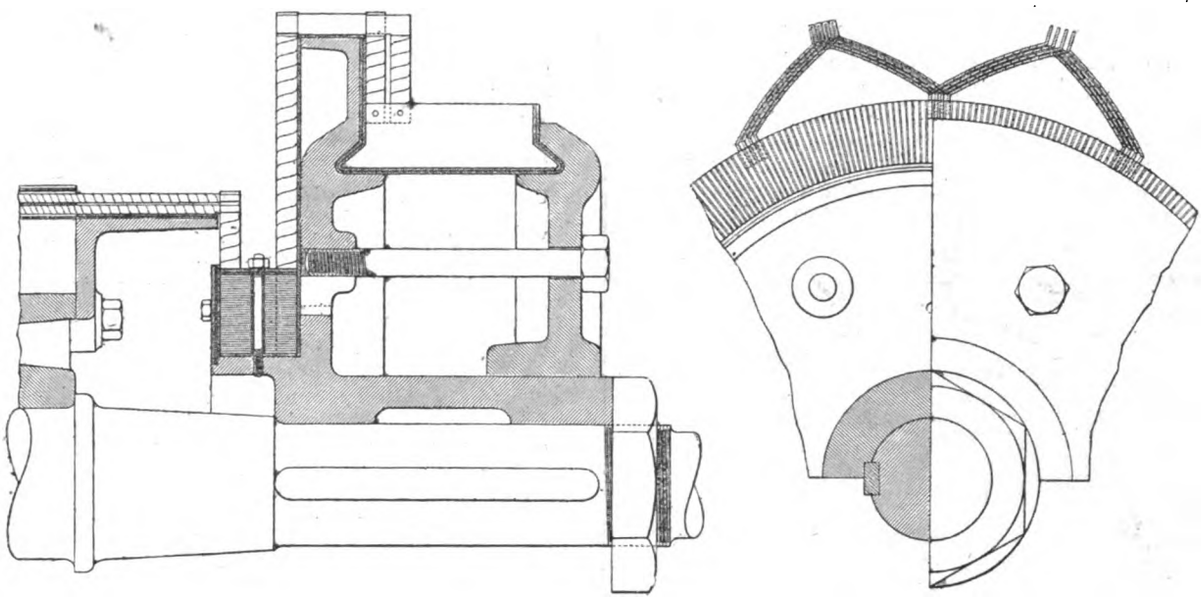

Fig. 43.—Detail of Connectors of Compounding Exciter.

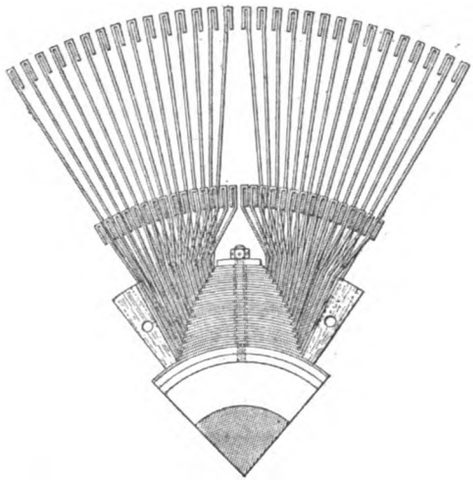

Fig. 44.—Detail of Connections of Compounding Exciter.

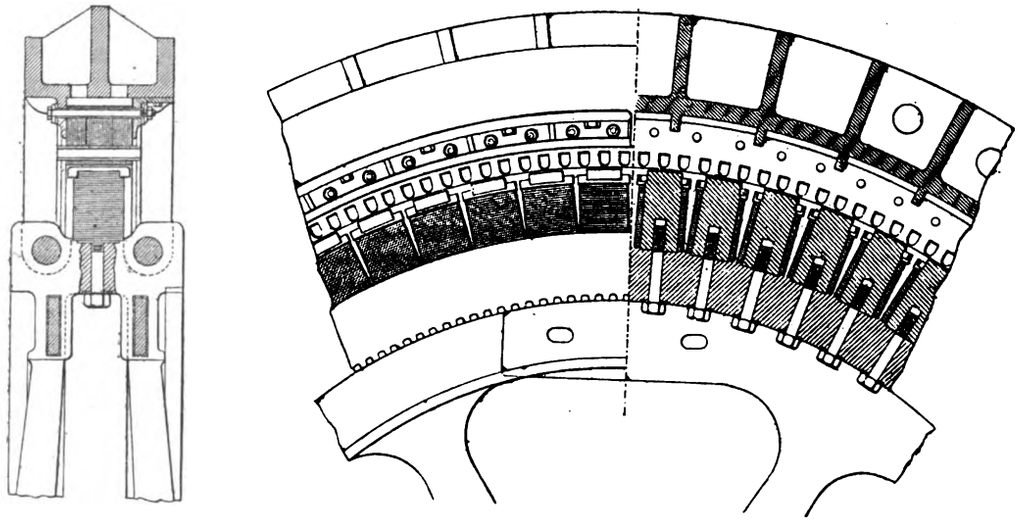

Fig. 45.—Detail of Grammont Alternator.

Digitized by Google

the windings are held in position against the action of centrifugal force by a solid brass washer. The flywheel was designed with regard to the fact that the engine was a single-cylinder one, so that the momentary variation in the speed at a fixed load should be less than 0·4 per cent.

The armature casting differs somewhat from the usual design, and consists of three vertical rings joined together by transverse ribs. There are holes in the partitions for the ventilation of the armature core. The core discs are divided into three packets, separated by ventilating ducts, and held together by a steel piece of L-shaped section. As seen in Fig. 45, the winding is placed in holes of a peculiar shape. Cardboard and micanite tubes, tested to 20,000 volts, insulate

A 38-Mile Electric Railway.—The longest third-rail electric railway yet built, says the *Railway and Engineering Review*, of Chicago, is about to be put into operation between Albany and Hudson, N.Y., a distance of 38 miles. The line has been built by the Albany and Hudson Railway and Power Co., on steam railway standards, a portion of the road being steam railway changed over to electric line. Power will be supplied from an 8,000 H.P. water-power plant at Stuyvesant Falls, on the Kinderhook Creek. The dynamos are 12,000-volt machines, the current being transmitted to a number of sub-stations along the line, where it will be transformed and converted to continuous current at 550 volts. The line runs through a section of fertile farm country, and will do a large freight business in connection with manufacturing industries along the route. It is also expected to handle large amounts of dairy and farm produce, as well as a large passenger business. For the protection of life and property along the route a woven wire fence of small mesh has been erected on either side of the road for its entire length. At road crossings the third rail is broken, the conductor being made continuous by means of a cable laid in an underground conduit. Signs have been posted conspicuously at all road crossings warning the public not to trespass. The electric freight locomotives will be similar to those used in the tunnel of the Baltimore and Ohio Railway at Baltimore. There appears to be an opinion in America that this railway is only part of a line to connect Albany and New York City, to be completed later on.

THE NEW ELECTRICITY WORKS OF THE GLASGOW CORPORATION.

(*Concluded from page 812.*)

POLLOKSHAWS ROAD WORKS.

This station fronts the Pollokshaws-road, the Barrhead and Kilmarnock joint railway being at the back. The engine-house and boiler-room floors are on the same level, and the coal store is contained in an elevated mild steel tank running the whole length of the boiler-house. The railway has a siding running right into the station underneath the coal store tank, and the coal waggons are raised by screw elevators to a high-level set of rails running along the top of the coal tanks. From the coal tanks the coal is discharged through shutes into the hoppers of the automatic chain grate stokers. The boilers are of the same size and make as those at the Port Dundas works, and the ashes are handled in a similar manner. The roof of the boiler-house is formed of mild steel tanks, with the exception of a 10ft. space over the stokehold, which is roofed with glass and iron and has louvre-boarded sides for ventilation, and a 4ft. space next to the engine-house wall which is roofed in a similar manner. When complete, this boiler-house will contain 20 Babcock and Wilcox boilers of 1,100 H.P. each, placed in a single line. There will be two chimneys, only one of which is built at present however, each

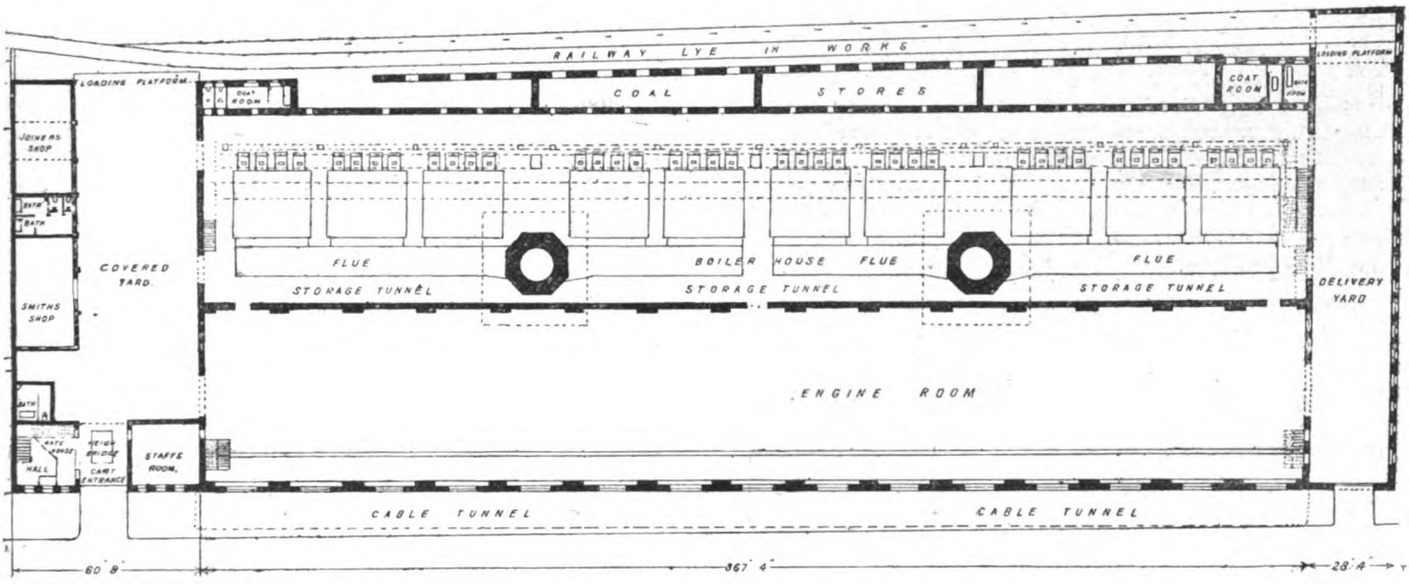
Engines and Dynamos.—One 1,100 H.P. Willans-Crompton set. Two 400 H.P. Belliss-Crompton sets. Two 200 H.P. Alley and McLellan-Mavor and Coulson sets.

Accumulators.—There are at present no accumulators at this station, but as soon as possible it is proposed to remove the two existing 200-volt Tudor batteries now in two of the sub-stations and re-erect them at this station making them up to two 250-volt batteries.

Seeing that the machinery is on exactly the same lines, and some of it exact duplicates of the plant at the Port Dundas station, no detailed description of it is necessary here. The one want at the station is a water supply for condensing purposes, but it is in contemplation to erect a cooling tower, or an evaporative condenser in the tanks already referred to over the boiler-house.

STREET WORK AND MAIN CABLES.

The laying of the supply mains in connection with the new scheme was commenced by the Corporation's own staff in June, 1898, and by June of this year 54½ miles of feeders and 63 miles of distributors had been laid, 41 miles of feeders



PLAN OF THE GENERATING STATION AT POLLOKSHAWS-ROAD.

and 47 miles of distributors being on the north side of the river, and 13½ miles of feeders and 16 miles of distributors being on the south side, the supply being extended through the more important thoroughfares over a 2-mile radius from the centre of the city.

The contract for practically the whole of the cables has been equally divided between the British Insulated Wire Co. and Callender's Construction Co. The feeders are triple concentric cables of 1, 1 and 0·3 sq. in. section, with the exception of four feeders laid in some of the residential parts of the area, which are of 0·5, 0·5 and 0·25 sq. in. section area. The 1 sq. in. triple concentric cable is, we believe, the largest cable of its class that has ever been constructed. The B.I.W. cable of this size has a diameter of $3\frac{1}{16}$in. The inner copper is composed of 91 wires, the middle conductor of 18 segmental strips, and the outer conductor of 24 segmental strips, the total weight of copper being 21 tons per mile. The total weight of lead used in the cable is nearly 19 tons per mile, and the total weight of the cable is over 44 tons per mile. The cable is manufactured in 110-yard lengths, and is packed on drums 6ft. 6in. diameter. The cable was submitted in Mr. Chamen's presence to a severe bending test, being bent backwards and forwards six times round the barrel of a drum 2ft. 6in. diameter, and it was then tested to a pressure of 30,000 volts without breaking down.

200ft. high and 11ft. diameter, and octagonal in section. If economisers are fitted they will be placed immediately over the flues.

The engine-room is 363ft. long, the same as the boiler-room, and 56ft. wide between butts, and is roofed with glass and iron and has side windows in the front wall. The interior is finished with enamelled bricks in colours, the exterior being built with red pressed bricks and red sandstone facings. The general fittings are the same as at Port Dundas, there being a 25-ton overhead electrical traveller, and a track along the side for a tank weighing machine for testing the steam consumption of the various engines. On the other side of the engine-room and running the whole length is the switchboard gallery, while underneath there is a tunnel 8ft. wide and 6ft. 9in. high (also running the whole length of the engine-room), along which all the cable connections are carried. There is another tunnel 11ft. wide on the other side of the engine-room wall and underneath the footpath. Above the delivery yard seen at the end of the works in the plan, the battery room is situated, while at the other end of the buildings there are the general offices, engineer's room, workshops and a covered yard.

The machinery whose erection is being completed is as follows :—

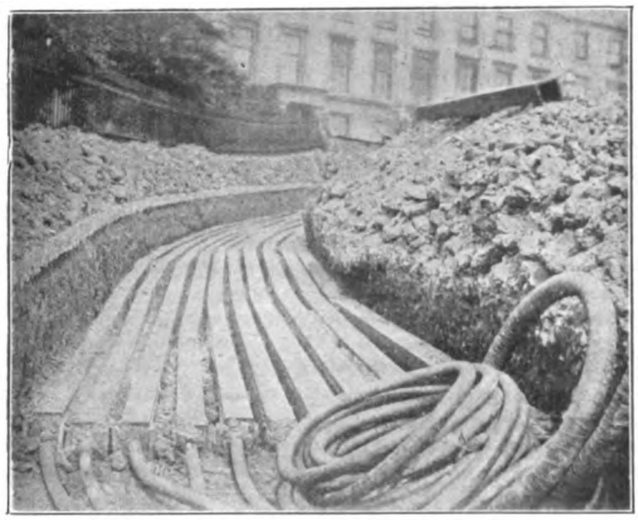
Boilers.—Four Babcock and Wilcox, 1,100 H.P. each.

Digitized by Google

The distributors are of 0·25 sq. in. section triple concentric cable, laid in the main thoroughfares in the centre of the city, and of 0·15 sq. in. triple concentric cable throughout the rest of the area.

Both feeders and distributors are insulated with resinous paper, vulcanised bitumen, or impregnated jute, and all except the vulcanised bitumen cables are lead-covered. They are laid in iron, earthenware, or wooden troughs, and are filled in solid with a composition of the best coal tar, pitch, and asphalt oil. On the three-wire system at 250 volts and 500 volts the core of the cable is positive, the centre conductor negative, and the outer conductor neutral The sheathing of all lead-covered cables entering the stations is bonded on to earth plates put down in the ground of the stations.

The feeders are brought into tunnels in the new stations, and run on supporting brackets up to points under their respective panels erected on the gallery in the engine-room. They are turned up through the floor and connected directly with the terminals at the back of the panels. From the tunnel the feeders are run in batches of from four to six at a time through the back streets to their respective feeding points, and where a feeder is dropped at a feeding point, the others pass into the feeding point manhole and out again through disconnecting links, so that there are several points at which the feeders may be disconnected or manipulated in cases of emergency.



Batch of six 0·5 Triple Concentric Vulcanised Bitumen Distributors and four 1 sq. in. Feeders, laid in the same Trench on the way to one of the Feeding Point Manholes.

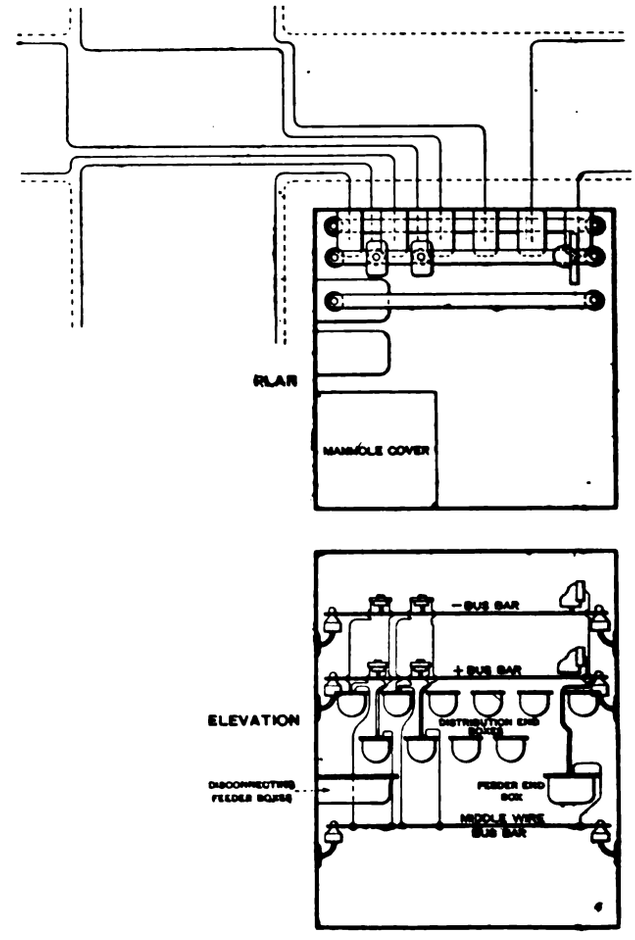
The feeding points consist of 6ft. square cast-iron chambers which are cast in eight sections and put together in position.

The cable is passed through a special design of cast-iron gland, attached to the outside of the manhole, and it terminates in a cast-iron end-connection box through which rubber connections are brought up; the positive and negative conductors being connected through fuses mounted on porcelains on to the positive and negative distributor 'bus bars. The middle wire connection is coupled directly to a middle wire 'bus bar. All three 'bus bars are mounted on porcelain insulators, but in the case of the positive and negative bars these are attached to porcelain fuse blocks, each of which is arranged for a supply to two distributors, the fuse blocks being mounted on a malleable iron bar which is supported at each end by a porcelain insulator. This arrangement tends to provide double security from any leakage taking place from either the positive or negative 'bus bars to earth. Care has been taken to abolish the use of wood, the designs for all fittings being in either iron or porcelain, thus minimising the fire risk. The distributors are brought into the manholes in an exactly similar manner to that described for the feeders, and for the positive and negative conductors the rubber connections are taken to the fuse terminals on the distributor fuse porcelains, strip tin being used for the fuses. The middle wire distributor connections are clamped directly to the middle wire 'bus bar.

The manholes are capable of receiving from eight to ten distributors, one feeder, and four sets of connecting links for other feeders. All the fittings are so arranged as to be easily dismantled or worked upon, a complete set of tools and accessories being kept in each manhole. An iron ladder gives access to the interior, and the manhole cover is designed with a view to keeping the manhole free from gas and surface water.

The plan published in our issue of Sept. 14 shows the present arrangement of feeders, the distributors on either side of the street having either one or two connecting links arranged by means of road crossings according to the length of network between the feeders.

Where one distributor joins another, a 2ft. square brick manhole is built in the footway. The distributor ends are brought into this manhole through end connection boxes of a similar design to those used at the feeding points, with the exception that the boxes have a socket end into which the



General Arrangement of Distributors at Feeding Point Manholes.

wood, earthenware or iron trough is brought, and this socket end is built into the brickwork and holds the box in position. The distributor ends are brought up to fuse terminals on porcelains, one side of the porcelain being arranged for a 'bus bar, and the other for the cable ends. All bare connections are within a few inches of the top of the box to minimise the risk of trouble should water get into the manhole.

In the case of lead-covered cables entering brick manholes, bonds are employed consisting of lead blocks in the form of a plummer block, the bonds being put round the cable inside the socket-end of the end connection box (the socket end of the box and lead of the cable being first thoroughly scraped), and an iron clamp is put round the outside of the socket and screwed down hard on to the lead bond, which is made to project slightly above the top of the socket. The end-connection box is then connected by a 10-gauge copper wire to an "earth plate," which in most cases consists of a 6ft. length of 4in. cast-iron pipe driven vertically into the soil.

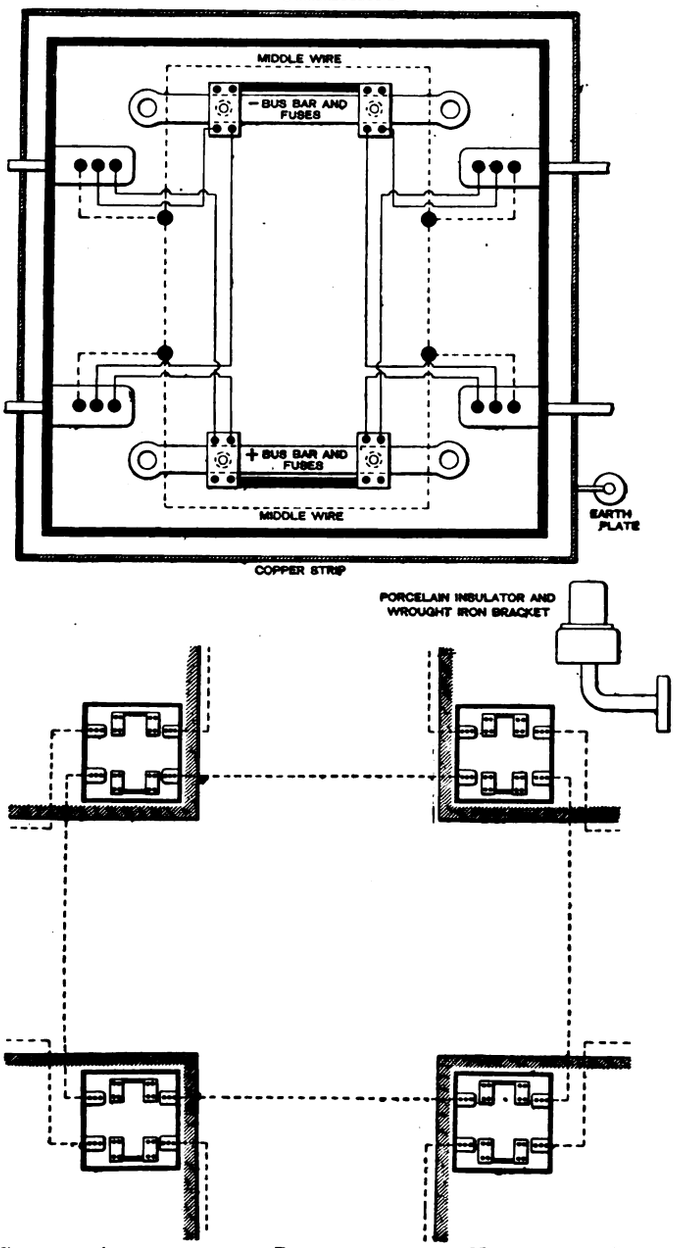
Services to consumers' installations are all put in with steel tape or lock coil armoured concentric cables, the branch joint boxes being designed with a view to facilitate the making of the joints when the cable is alive, where this is absolutely necessary. Care is taken to connect mechanically the lead covering of lead-sheathed cables across the joint box by means of the method of bonding above described, the boxes being designed with socket ends for this purpose. The service main terminates in a Corporation fuse box of two fuses, if for a concentric, or four fuses if for a triple concentric service, the four fuses being with a view to splitting a consumer's installation into two distinct circuits to meet the Board of Trade

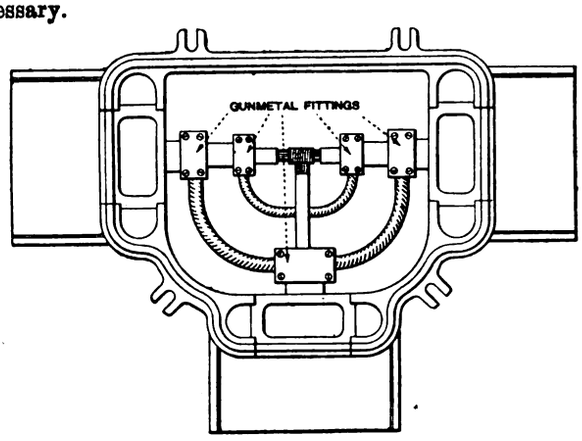
Details of General Arrangement for Distributor Manhole Connections.



General Arrangement of Distribution from Manholes at Street Corners.

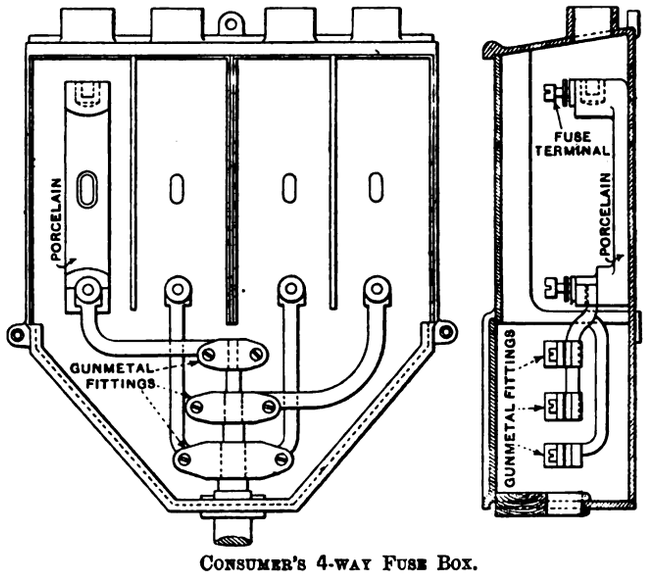
requirements where large installations are concerned. In both cases the fuses are enclosed in a cast-iron box of special design, the concentric having one and the triple concentric two lids.

One of our illustrations shows the general arrangement of the box. The porcelains are designed so that the gunmetal fittings slip into sockets at either end when sweated to the cables, each porcelain being secured in position by means of sulphur cement poured into a recess in its centre, which grips a snug forming part of the cast-iron box. The box is also cast with a fillet between porcelains holding terminals of opposite polarity, this fillet being lined with mica. The lid or lids are attached to the box by snugs, one snug for each lid being arranged to receive a lead seal, which, when in position, secures the lid. Glass fronts are fixed in the lid opposite and for the full length of each fuse, the lids being bevelled on the inside round the glass in such a manner as to ventilate the box without allowing of the fuses being tampered with. On the tops of the boxes are sockets through which the house mains pass to the fuses, the sockets being plugged with wood and sealed with compound, where wood casing is used, or provided with nipples, to which pipes may be screwed if necessary.



Plan of Cast-iron Branch Box.

The department is at present busily employed changing-over consumers from the low-pressure supply from the original stations at Waterloo-street and Kelvinside to the supply from the new stations. The last of the Kelvinside section of mains was changed over on August 3, 1900. In arranging for the change-over, the outlying districts have been attacked first, with a view to enclosing the old area and hemming it in gradually towards the old generating station at Waterloo-street. Owing, however, to the large number of new blocks of offices in the centre of the city, all of which are entirely dependent upon electricity for lighting and motive power (the motive power being at 500 volts) it has been necessary to deal with certain portions of the centre of the city without delay.



Consumer's 4-way Fuse Box.

The system is worked with the middle wire earthed through a batch of twelve 100 c.p. 250-volt incandescent lamps in series with an "earth" recording ammeter. The outer conductors of the triple concentric feeders are tested for insulation to earth once a week, and a daily test of the general insulation of the whole network is made without interrupting the supply, by noting the current passed by a few cells through the middle wire with one pole of the battery connected to the middle wire and the other to earth. By this means any defect in the insulation of the outer conductor in the triple-concentric cables is noted, and in several cases faults,

Digitized by Google

due to pick holes, &c., have been localised before any serious results have come to the cables.

Owing to the south side generating station not yet being ready to start supply, a portion of the south side area has been supplied from the Port Dundas station through a feeder and trunk mains of 1 sq. in. section laid across Glasgow Bridge, and arrangements have been made by which the two stations can be paralleled when required through several 1 sq. in. trunk mains which cross the bridge, and from connecting links between feeding points on either side of the river. The whole of the south side distributors will be working from the Pollokshaws-road station by October of this year.

There are at present 265 public arc lamps in use and an extension consisting of another 450 lamps is in progress. The lamps are 32-hour lamps, connected in series of 10 to the outers of the 500-volt distributors. The lamps are either suspended from lamp columns erected on the sides of the streets, or from the posts carrying the overhead wires for the electric tramway system. In the bases of the columns or tramway posts, each lamp is provided with a substitutional resistance switch, and the resistances for these and in connection with the automatic cut-out on the lamps, are also mounted in the bases.

The lead between the fifth and sixth lamp in a series of 10 is taken through one of the distributor disconnecting manholes, and arranged so that by putting in a fuse between the lamp lead and the middle wire distributor, half of the lamps on the circuit may be run independently of the other, so that, in the case of a breakdown on a section of the network or arc lead, no more than five lamps need be out at a time.

All fittings for the manholes and jointings are manufactured in the Corporation workshop at 81, John-street, City, plant being put down for that purpose in the engine and boiler-house of what was the original generating station when the Corporation first started an electricity supply for public lighting. The mains department is controlled from the electricity department head offices, and the city is divided into four sections, each section being in charge of a district superintendent who has an office and stores in his particular district in telephonic communication with the head office.

We cannot conclude this account without a few words as to the *personnel* of the electricity department who have so successfully carried out this huge work. As convener of the Electricity committee, Bailie Maclay has been most energetic, and his name will be well known to our readers through the papers that he has from time to time read, dealing with the commercial aspects of electrical supply. Bailie Maclay's efforts have been well seconded by Bailie Willock, upon whom, as the convener of the Works committee, a very large proportion of the work came. As to Mr. Chamen, himself, our description of the new works describes also the efficient way in which he has executed his task. Mr. Wm. Lackie, Mr. Chamen's chief assistant, has been with the Glasgow Corporation ever since they have had an electrical department, and in fact we believe we are correct in stating that he was one of the assets taken over from Messrs. Muir, Mavor and Coulson. Owing, therefore, to his intimate knowledge of the town and its electrical undertaking, Mr. Chamen has found him invaluable in relieving him of a large amount of work. Mr. Ward, the mains superintendent, who came to Glasgow from St. Pancras, had not only to carry out the large amount of cable work described above, but to organise the department, teach the men, design all the fittings, not to mention the trouble of keeping the original rubber-covered and bare copper conductors in a workable state till they were able to be gradually replaced. As resident engineer at Port Dundas and, since Mr. Christie's promotion to Brighton, as station engineer, Mr. Poole has shown great energy, and now that the stations are opened and therefore presumably near completion, he hopes to get his staff into smooth working order under the resident engineers, Mr. Page at Port Dundas, and Mr. Thomson at Pollokshaws-road. We must not forget either Mr. McEwan, whose enthusiasm in carrying out Mr. Chamen's ideas in the design of the various switch gear was most keen. Mr. Calderwood, the chief draughtsman, has given Mr. Chamen much assistance in working out the details and superintending the installation of the new plant. We wish to express our thanks to all these gentlemen, who, in their various departments, have rendered us great assistance in compiling this article.

THE OSMOTIC PRESSURE THEORY OF PRIMARY CELLS.*

BY W. R. COOPER, B.SC.

Osmotic Pressure.—The nature of osmotic pressure will be most readily understood by referring to the following simple experiment. In Fig. 1 the vessel A is the head of an inverted thistle funnel, the stem being broken off. Across the top is stretched a piece of bladder which is tied round the funnel. In order to make a water-tight joint, the bladder should first be made wet with hot water, so as to obtain an even surface, after which it is slightly dried. The funnel is made hot, and some Chatterton insulating compound is quickly applied all round the edge. While the Chatterton is still hot, the funnel is placed top downwards upon the bladder, which is then tied round the edge. If properly carried out, a perfectly water-tight joint will result. When the vessel so formed is complete, it is filled nearly to the top of the neck with a strong solution of sugar, and joined by a good-fitting piece of rubber tubing, B, to a fine capillary glass tube, C. By slowly pushing the latter down into the vessel A the level of the sugar solution in the capillary tube may be adjusted to any desired height. The vessel A is now immersed in a beaker of water, D. For the first hour or two very little may happen. Possibly the level in the capillary tube will even fall. But at the end of a day, a very decided rise will be observed, due to what is termed the osmotic pressure of the sugar. As soon as the diaphragm assumes a steady state the rise is rapid. With a tube of about ½mm. bore and a funnel 1¼in. diameter the author has observed a rise of 11 cm. in 20 minutes.

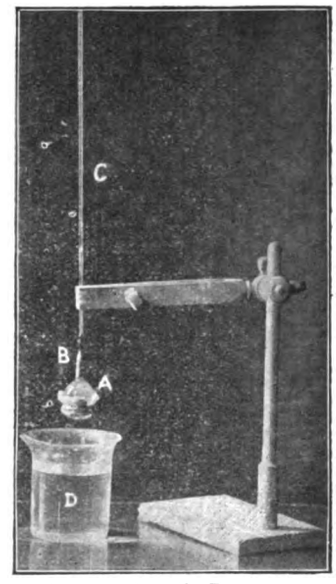


FIG. 1.—Osmotic Pressure.

This pressure is generally explained by saying that the sugar molecules are striving to pass through the membrane into the water. The membrane acts like a molecular filter, being impermeable to the sugar molecules, but permeable to the water molecules; and so the water passes inwards, but there is little or no exit of sugar if the membrane is suitable. Various membranes are employed in experiments of this kind, artificial ones being the most effective.

The pressure so observed, which may amount to several atmospheres, is generally regarded as the pressure exerted by the sugar molecules. On observing the osmotic pressures of various solutions, it is found that equi-molecular solutions exert equal osmotic pressures, irrespective of the solvent, thus showing that the pressure depends upon the number of the molecules in solution per unit volume. This result is similar to the law of Avogadro for gases, which states that equal volumes of gases measured under the same temperature and pressure contain the same number of molecules.

As the result of a number of experiments, Pfeffer found that the osmotic pressure of a solution is proportional to the concentration and to the absolute temperature. Now the concen-

* From a book on "Primary Batteries," shortly to be published by *The Electrician* Printing and Publishing Co. All rights reserved.

tration of a solution is the reciprocal of its volume. We may therefore write this result in the form

$$P = R' \frac{1}{V} T,$$

or

$$PV = R'T,$$

in which P is the osmotic pressure, V the volume, R' a constant, and T the absolute temperature.

Van't Hoff was the first to point out the striking analogy between this result and the laws of Boyle and Charles, which are embodied in the well-known equation referring to gases, viz. :—

$$pv = RT,$$

in which the letters have similar significations to those in the previous equation, the only difference being that in the former we are dealing with a volume of solution, whereas in the latter a volume of gas is in question. Upon investigating the results of Pfeffer, van't Hoff found that the values of the constants R and R' in the two equations were practically the same, whence he came to the following remarkable conclusion: The osmotic pressure exerted by the molecules of a given weight of substance in solution is equal to the pressure which an equal weight of the substance would exert at the same temperature if it occupied a volume in the gaseous state equal to that of the solution.

It thus appears that a substance in solution (at least when *dilute*) acts in the same manner as a gas, and the laws of Avogadro, Boyle and Charles all apply to such solutions if the osmotic pressure be substituted for the gaseous pressure. It is therefore concluded that, in the process of dissolving, a substance breaks up to a very large extent into separate molecules. When the solution is sufficiently dilute all the molecules assume a separate existence, and the osmotic pressure then becomes a measure of the number of molecules present. Such, briefly, is van't Hoff's theory of solutions.

Electrolytic Solution Pressure.—When evaporation takes place from a liquid in a closed vessel, it continues until the pressure of the vapour so formed reaches a certain value, depending upon the temperature and upon the liquid. After this maximum value of the vapour pressure is reached, the condensation which then takes place is equal to the evaporation; although molecules may still be regarded as escaping from the liquid mass into the gaseous, an equal number are passing back from the vapour into the liquid, and so a state of equilibrium is established in which the vapour pressure is equal to and opposes the tendency of the liquid to pass into vapour. In the same way the osmotic pressure of a saturated solution which is in contact with some of the undissolved solid substance may be looked upon as a measure of the "solution pressure" of the substance, or of its tendency to pass into solution.

In order to account for the E.M.F., or the difference of potential, between a metal and any electrolyte in which it is immersed, Nernst introduced the idea of "electrolytic solution pressure" of the metals. This is analogous to vapour pressure, and indicates or measures the tendency of a metal to pass into free ions when placed in an electrolyte. These free ions are positively charged, and therefore also the electrolyte containing them. Since both kinds of electricity result simultaneously, the metal must be negatively electrified, and will attract the positive ions to it. What is called a "double layer" of electricities results at the surface of separation between the metal and electrolyte. As soon as the attraction of the metal for the positive ions is equal to the solution pressure, equilibrium is established, and no more ions pass into solution. If they did so, the electrostatic attraction would become greater than the solution pressure, and the reverse process would set in—viz., ions would pass back into the molecular state. Very few ions suffice to bring about this equilibrium, because the ionic charges are large.

In the case of a liquid containing no ions of the metal in question, the value of the E.M.F. depends only upon the solution pressure. But if ions of the metal are present, the solution pressure is opposed by the osmotic partial pressure of the cathions, and the E.M.F. is smaller. Let P be the solution pressure, and p the osmotic partial pressure due to the metallic ions already present. Three cases are possible. First, $P > p$: metal ions are produced and the metal becomes negatively electrified; but since the osmotic pressure opposes the solution pressure, the number of ions, and therefore also the E.M.F. so produced, is smaller than it would be if no ions were initially present. Secondly, $P = p$: in this case the metal does not become charged, because no more metallic ions can be produced, and therefore no E.M.F. results. Thirdly, $P < p$: in this case cathions are precipitated, as it were, upon the metal, to which they give up their positive charges until the electrification is sufficient to repel the remaining cathions. Consequently the metal is positively electrified and the solution negatively, an E.M.F. being produced which is opposite in sign to that in the first case, where P is greater than p.

Let us now calculate the value of this E.M.F. The ions at the surface of the metal where the "double layer" is formed may be looked upon as being under a pressure equal to the solution pressure, whereas any ions in solution are under a pressure equal to the osmotic partial pressure of those ions. If a current flows, due to the E.M.F., the ions pass from the pressure P to that of p, and in this change of pressure a certain amount of work must be done by the ions. Suppose gas under a pressure p to be confined in a cylinder, as indicated in Fig. 2, by a piston of area A. Then the total pressure outward upon the piston is pA. If the piston is allowed to move a very short distance, dx, outwards, so short that the pressure remains practically constant, the work done by the gas in so moving the piston is $pA dx$. But $A dx$ is the variation in volume, or dv, caused by the motion; and so the work done is equal to the pressure multiplied by the change in volume. The total work done in varying from a volume v_1 to v_2 is given by the sum of such quantities, or by the integral

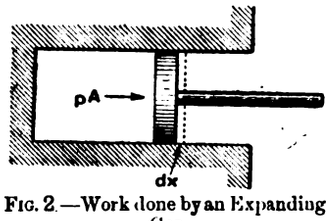

FIG. 2.—Work done by an Expanding Gas.

$$\int_{v_1}^{v_2} p\,dv.$$

Since we have in gases the relation $pv = RT$, the integral assumes the following value, viz. : —

$$RT \int_{v_1}^{v_2} \frac{dv}{v}$$

$$= RT \log \frac{v_2}{v_1} = RT \log \frac{p_1}{p_2},$$

where p_1, p_2 are the pressures corresponding with v_1, v_2. In this expression the value of the constant R depends upon the basis on which we start: it is equal to the product of a volume into a pressure divided by the absolute temperature of the gas. If a given volume of gas be taken at a given temperature, the pressure is not defined by these two quantities, because it still depends upon the mass of gas with which we are dealing. By forcing more gas into the given volume the pressure would be changed, and the apparent value of the constant would also change. It is therefore necessary to deal with a definite mass. In our case the most convenient unit of mass is the gramme molecule. It will be remembered that a gramme molecule in the gaseous state occupies a volume of 22·38 litres at the normal pressure of 760 millimetres of mercury and at the normal absolute temperature of 273deg. All our quantities are then defined, and the value of R, expressed as heat, is found on this basis to be 2 gramme-calories. With this value for R, the expressions given above represent the work done when a gramme molecule of a gas changes from the volume v_1 to v_2, or from the pressure p_1 to p_2.

We may now continue the calculation of the E.M.F. When a current flows from the metal to the solution, metallic ions pass from under a solution pressure P to the osmotic partial pressure p. If the electrolyte is a dilute salt-solution of the metal, supposed to be *monovalent*, it may be looked upon as completely ionised into equal numbers of two ions, and the value of p will then be equal to half the osmotic pressure—*i.e.*, to the whole osmotic pressure which would result if no ionisation were to take place. Since the solute in a dilute solution obeys the gaseous laws, we may apply the

Digitized by Google

results which we have just obtained for a gas. It thus appears that when a gramme equivalent of a metal passes voltaically into solution, giving a gramme molecule of the salt, work is done to the extent of $RT \log \frac{P}{p}$. But if E is the E.M.F. at the metal-liquid junction, and the work is wholly converted into electrical energy, this work is also equal to 96,500 E, because 96,500 coulombs of electricity are required to decompose one gramme molecule. Thus we have the relation

$$96{,}500E = RT \log \frac{P}{p}.$$

The left hand side of this equation is expressed as work, and therefore R must also be expressed in that way. As already stated, it is equal to 2 gramme-calories, and thus to $2 \times 42 \times 10^6$ C.G.S. units of work. Remembering that a coulomb is $\frac{1}{10}$ of the C.G.S. unit, and that a volt is 10^8 C.G.S. units, we have for the value of the E.M.F. in volts

$$E = \frac{2 \times 42 \times 10^6}{96{,}500 \times 10^{-1} \times 10^8} T \log \frac{P}{p}$$
$$= 0{\cdot}000087 T \log \frac{P}{p}$$
$$= 0{\cdot}0002 T \log_{10} \frac{P}{p},$$

the last value being obtained by converting the logarithms to the ordinary base of 10. If the temperature is 15°C., then T = 288, and

$$E = 0{\cdot}0575 \log_{10} \frac{P}{p} \qquad \text{at } 15°C.$$

If the metal is not univalent, we have the more general formula

$$E = \frac{0\,0575}{n} \log_{10} \frac{P}{p},$$

in which n is the valency.

Now consider the E.M.F. of a reversible cell, such as a Daniell. Here we have four contacts. The metal/metal and liquid/liquid contacts only give rise to small E.M.F.s which may in the first instance be neglected. At each of the metal/liquid junctions, however, we have metallic ions seeking to pass into solution; but this can only take place at one plate, deposition being necessary at the other. Consequently the E.M.F. takes the form

$$E = 0{\cdot}0002 T \left(\frac{1}{n} \log_{10} \frac{P}{p} - \frac{1}{n'} \log_{10} \frac{P'}{p'} \right),$$

in which the two component E.M.F.s oppose each other. The sign of either term in itself depends, of course, upon the solution pressure being greater or less than the osmotic pressure. In this expression the forces are supposed to be in equilibrium. It is the E.M.F. on open circuit, in which state the solution pressure diminished by the osmotic pressure of the metallic ions is equal to the electrostatic attraction of the double layer. But when the negative charge on the zinc is removed by closing the circuit, this equilibrium ceases. The positive charge of the double layer is then no longer bound, and consequently the solution pressure gives rise to more free ions; the zinc passes voltaically into solution and a continuous current is generated.

This theory of E.M.F. has been indirectly confirmed in many ways. For example, if the valencies n and n' are the same, and if the concentration of the ions is the same for both solutions, or $p = p'$, the formula simplifies to

$$E = 0{\cdot}0002 T \log_{10} \frac{P}{P'}.$$

In such a case the E.M.F. depends only upon the solution pressures, and, if the salts are assumed to be completely ionised, it does not change when the concentration of both solutions varies in the same way. That is to say, if the E.M.F. of a Daniell cell is 1·07 volts for given concentrations, it will remain at this value if the concentrations of the zinc sulphate and copper sulphate solutions are increased or decreased by the same amount. This result is easy to understand. An increase, for instance, in the concentration diminishes the E.M.F. at both plates; but, as these E.M.F.s oppose one another, the resultant E.M.F. remains constant. This is found to be approximately the case.

(To be concluded.)

ELECTRICITY WORKS ACCOUNTS.

Bury Municipal Electric Supply Works.

The management of the Bury undertaking is to be congratulated on having brought it to a self-sustaining stage in the third year of working.

Our analysis shows the satisfactory result for the year 1899-1900 of a net profit of £183 after satisfying capital charges to the extent of 4·9 per cent. of the mean capital expended, and with the moderate total revenue from all sources of but 4·1d. per unit.

While the items of fuel and oil, waste, water, and stores have risen slightly, the remaining two items of generating costs have diminished, and all stand at figures below the average at the same output and load factor.

Owing to increases in the public lighting and distribution items the works costs show a slight upward tendency to be again more than neutralised by the drop in the management and property charges, which now show a normal figure.

The total costs, as well as the collective generating costs, are quite 0·5d. below what they might reasonably have been expected to stand at.

As for the progress made by the concern during the year, the lamp connections have increased by 43·4 per cent., and the output from 115,853 units sold to 213,395, or by 84 per cent. A most satisfactory change for the better has taken place in the load-factor, which in 1898-9 was but 9·19 per cent. Last year it worked out at 12·37 per cent. This improvement was partly due to increased street arc lighting. The private lighting load-factor was 11 per cent.

Extensions of plant have taken place by the instalment of a 30ft. by 7ft. Lancashire boiler and a 250kw. Belliss and Morcom vertical tandem compound condensing engine, combined with a Siemens two-pole dynamo for 500 amperes at 440 volts to 500 volts. This set is provided with a heavy fly-wheel for supplying energy for traction purposes, if necessary. Owing to the change to the higher pressure, the battery cells have been increased in number from 130 to 260. A balancer and booster set has also been installed. The balancing machines are capable of transferring 200 amperes at 220 volts to 250 volts from one side to the other of the three wire syetem, The two boosters are mounted on an extension of the main shaft of the balancer, and are each capable of an output of 100 amperes at 100 volts being used to give the extra pressure for charging the cells.

Pontypool Electric Light and Power Co. (Ltd.).

This little undertaking is interesting because of the disadvantageous conditions of low output and load-factor under which it is carrred out. It is seldom that we have to deal with the accounts of a concern with an output of only 58,201 units sold, in combination with a load-factor of 6·71 per cent.—a business at the same time mature in having completed its sixth year of working.

Judging the results of the year by themselves, they are in many respects excellent. Both the fuel and repairs items are considerably below what they might have been expected to be. The management and property charges are also very low considering the conditions; but, on the other hand, the oil, waste, water and stores, and the wages items are relatively heavy. The resulting works—and total—costs are most commendable, and might well have been associated with an output five times that at Pontypool.

It is a pity that the business makes such slow progress. Last year the increase in the lamp connections was only 8·17 per cent. and in the output but 13 per cent.

The load-factor at 6·71 per cent. certainly shows a slight improvement over the corresponding figure of 6·47 per cent. in 1898, but it is still abnormally low.

We are glad to note that the company have contracted to maintain six arc lamps for the District Council. This will probably help to improve the character of the load.

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny
Editorial Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co."

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"The Electrician" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	12s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	

New Volumes of "The Electrician" *commence in April and October.*

"The Electrician" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints" on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By E. Trembluy Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d., post free 13s. Vol. II. Price 12s. 6d.; post free, 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. New Edition. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. New Edition. 93 original illustrations, price 6s.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. New edition. Price 10s. 6d., post free; abroad 11s.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d. post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d.; post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gnipel and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free 2s. 2d. each; strong cloth 2s. 6d., post free 2s. 9d. each. Single Primers 2d., post free 2½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O. J. Lodge. New Edition. Price 5s. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, ELECTRIC TRACTION, TELEGRAPHS, TELEPHONES, &c. A. C. Curtis-Hayward, B.A. To January, 1900. Price 3s. 6d., post free.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work is in the press and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By R. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. Raphael. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

THE TELEPHONE.—By Dane Sinclair and F. C. Raphael.

SPECIAL NOTICES.

NOW READY.—Vol. XLIV. of "The Electrician" (950 pages) bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of "The Electrician" (1878-1900) can now be supplied. These sets are very scarce, and early application should be made

NOW READY.—"THE ELECTRICIAN" READING CASE. Holds four copies of the Journal. Strongly made and corded for hanging. Price 1s.; post free, 1s. 4d.

THE MEASUREMENT OF LIGHT.

While in many fundamental physical measurements, notably those of weight, time, length, and electrical resistance, accuracy has been carried so far as to eliminate all errors exceeding one part in a million, the measurement of the intensity of light has as yet barely attained an accuracy of 99 per cent. This is due not only to the difficulty of obtaining a luminous surface of never-changing brightness, but also to the difficulty which the human eye experiences in judging whether two surfaces placed side by side have the same brightness. As long as photometry is hampered by the necessity of thus comparing two surfaces—and that is the only practical method hitherto devised—it is useless to expect a sensitiveness exceeding that of the human eye, the sole adjudicator. And there is hardly a human eye which could distinguish between a surface of brightness, say 150, and of brightness, 151. Much has been done of late, however, to aid the eye in making fine distinctions. The two surfaces to be compared have been brought into absolute contact by Lummer and Brodhun's compound prism, and unnecessary fatigue of the eye has been obviated by Mathews's recording device, which enables the observer to take his readings in the dark. But the provision of a standard of light has hardly kept pace with these improvements. In the measurement of light no standard is ready to hand, as is a certain lump of platinum in weighing, or the motion of the heavenly bodies in measurements of time. In measuring temperatures, imperfect though our methods are as yet, we have a number of fixed fusing points and boiling points always available. But stationed as we are on the earth's surface, no natural light is constant enough for comparison, and we have therefore to look out for some constant and reproducible artificial light. This, unless we adopt Henry's zinc sulphide phosphorescent screen, means high temperatures, and, since we usually require white light, it means very high temperatures. Such temperatures can as yet only be generated by flames and by electric incandescence, and we must find the method which furnishes the most trustworthy standard

Digitized by Google

for general reproduction. M. VIOLLE's report to the Paris Electrical Congress, of which we give a full abstract in this number, forms a valuable criticism of standards and instruments so far proposed and adopted. Two things are practically required. One of them is a first-class scientific standard of light capable of being reproduced with an accuracy of one in a million. The other is an instrument capable of comparing two luminous intensities with the same accuracy. When we have those two things, a solid basis will have been laid for a sound system of photometry. After that, it will be the business of instrument makers to bring an accuracy of at least one in a thousand within the reach of every lamp manufacturer and central station engineer. How far we are still behind this demand may be seen from every line of M. VIOLLE's report. The utmost constancy attained by any of the usual standards, Hefner—Carcel, or pentane lamp—leaves errors of 1 per cent., and the utmost accuracy claimed for LUMMER and BRODHUN's prism photometer is 0·5 per cent. PETAVEL's researches hold out a hope that the most truly scientific standard yet devised, the Violle standard of fusing platinum, may be made practically available. It may also be found possible to press the incandescent lamp further into service, or to devise a flame which will always have the same shape and constitution, and be unaffected by moisture or gaseous impurities. But such progress must be accompanied by new methods of photometry. If, for instance, a selenium or other cell were discovered whose resistance was affected by light, and by light only, to precisely the same extent as is the human eye, then the high level attained in the measurement of resistance would be immediately at our command for the measurement of light. Instead of comparing the luminosities of two patches, we should, as in all accurate measurements, control the coincidence of two lines, usually a scale division and a pointer. But until that is done we must be content with the rough-and-ready methods now available, the least troublesome being perhaps the standard incandescent lamp used with an oil lamp *à la* ROWLAND, and, if possible, with a LUMMER-BRODHUN prism.

REVIEWS.

(Copies of any of the undermentioned works can be had from *The Electrician* office post free, on receipt of published price.)

Traité de Magnétisme Terrestre. By Prof. E. MASCART. (Paris: Gauthier-Villars, 1900.) 15fr.

The author explains in his preface that this work took its origin in lectures delivered to French naval officers in 1882. These lectures he subsequently supplemented at the Collège de France and the École Supérieure de Marine. He states that his first object was to put magnetic observers in a position to understand the phenomena they have to deal with, and to use their instruments. After accomplishing this part of his programme, he found it impossible, in the limits of a single volume, to deal in detail with other than the more fundamental ideas and firmly established facts of terrestrial magnetism. This explains the relatively large amount of space devoted to preliminary matter.

Chapters I., II. and III., pp. 1-50, develop the elementary theory of bar magnets and uniformly magnetised spheres and ellipsoids; whilst Chapter IV., pp. 51-74, deals with electric currents and coils. The methods are similar to those adopted in Mascart and Joubert's treatise. Chapter V., pp. 75-133, treats of properties of magnets of which a knowledge is required in reducing magnetic observations. Chapters VI. and VII., pp. 134-188, describe a variety of instruments employed in *absolute* observations, and the procedure followed in their use. Chapter VIII., pp. 189-205, and Chapter IX., pp. 206-219, are respectively devoted to *variation* instruments and to absolute instruments suitable for travellers. Chapter X., pp. 220-304, discusses the treatment of observational results and the application of Fourier's series. Then, after a brief historical *résumé* it deals with secular variation, solar diurnal and lunar diurnal variations, disturbances, the interrelationships of magnetic and sun-spot phenomena and some minor problems. Chapter XI., pp. 305-342, treats of magnetic charts, surveys, disturbed areas, and the general theory of a magnetic potential. Chapter XII., pp. 343-376, discusses the potential more fully, explains the Gaussian analysis, and discusses the subject of earth-air electric currents. It contains a long mathematical calculation of the action of the sun regarded as a rotating magnet. It also explains Schuster's calculation of a diurnal variation potential and gives an account of Wilde's "Magnetarium." Chapter XIII., pp. 377-401, deals in a summary fashion with atmospheric electricity, aurora, earth currents, disturbance from industrial currents, and earth tremors. Chapter XIV., pp. 402-436, is devoted to ships' magnetism. A table of contents completes the book.

An experimental matter treated with unusual fullness in Chapter V. is the *temporary* induction in bar magnets. The author holds (Arts. 27, 46) that in a bar magnet vibrating in the earth's field the transverse magnetisation is likely to be appreciable unless the length equals 20 or 30 diameters; also that the temporary magnetisation is greater when the earth's field opposes than when it reinforces the permanent moment. The latter conclusion seems based on Lamont's experiments, but it is opposed to more recent experiments in Germany by Kohlrausch and others. A second important subject dealt with in Chapter V. is the action between two magnets. Each is supposed replaceable by a pair of poles. When the magnets are in the position usually adopted in the deflection part of a horizontal force experiment the couple between them is $2MM'R^{-3}(1+pR^{-2}+qR^{-4}+\ldots)$, where M and M' are the moments of the magnets, R the distance between their centres, and p, q constants. As it is customary to neglect qR^{-4}, it is desirable that q should be small. According to Lamont's analysis, which the author adopts, q vanishes when the polar distance of the deflecting magnet is longer than that of the deflected in the ratio 2·15:1. This result is given correctly (p. 115), but still the most desirable ratio of the lengths is said to be 2:1. Whether the statement is intended for an approximation, or is due to a confusion between Lamont's two fundamental positions, is, perhaps, rather an academic question, in view of the author's statement (p. 84) that he has observed the polar distance of a magnet decrease from 0·88 to 0 69 of its length as its magnetisation was diminished. Another point of interest is the best ratio between the two distances at which deflection observations are taken. A mathematical investigation on p. 118 makes the ratio 1·29:1, while Maxwell, following Airy, makes it 1·3189:1. The discrepancy arises, apparently, from the different ways of interpreting the physical problem mathematically.

Amongst the instruments described in Chaps. VI. to IX. are representatives of the old style with large magnets, Kew-pattern instruments, and modern French instruments, including an earth inductor. The descriptions, combined with the excellent illustrations, should suffice for the ordinary reader, but observers such as naval officers might possibly profit more from a minuter study of the particular instruments they have to use (*c.f.* Stewart and Gee's "Practical Physics," Vol. II., Chap. VI.). With reference to Fig. 49 and the accompanying remarks on the Kew-pattern magnetograph, it may be explained that eye-reading telescopes are not an essential part, being, in fact, non-existent in the Kew magnetic chamber itself. The arrangements there differ in some other details from Fig. 49, and the curves—especially those of vertical force—are less easily standardised than the remarks on p. 202 would suggest. In the Mascart magnetograph a single sheet of paper suffices for the declination, horizontal force, and vertical force traces, and only one lamp is used. The author regards the three lights and three sheets which he supposes daily used at Kew as "*Une dépense . . . qu'il est utile de réduire*"; and he takes a somewhat similar view on p. 199 of Wild's arrangements for securing uniform temperature at Pawlowsk. As a matter of fact, two days' traces are taken on

Digitized by Google

each sheet with the Kew magnetograph, and most of the recently-built magnetic chambers—*e.g.*, those at Potsdam, Washington, and Utrecht—are evidence that Wild's views are those generally held. The elimination of the annual temperature variation has at least many points in its favour, and a description of a thoroughly up-to-date magnetic chamber would have been useful.

Chapter X. is practically the first dealing with observational results. Its discussion of secular variation is somewhat slight, but is supplemented to some extent in later chapters. More space is devoted to diurnal variation (solar and lunar) and to the periodic phenomena of disturbances. Numerical data are taken from a variety of sources, notably the recent valuable analyses of Parc St. Maur (Paris) results by Moureaux, and of Batavia results by Van der Stok and Figee, and the older British and Colonial data discussed by Sabine, which figure so prominently in Walker's "Terrestrial and Cosmical Magnetism" and Balfour Stewart's article in the "Encyclopædia Britannica."

In his tables and curves of diurnal variation the author sometimes takes westerly declination as positive, and sometimes easterly, following apparently the practice of the original publication. An explicit statement as to which direction is positive seems sometimes wanting, and even a careful reader will occasionally experience a doubt.

The solar diurnal variation is illustrated by curves of three types. The first has times for abscissæ and magnetic variations for ordinates. The second type is a plane orthogonal projection of the spherical curve traced by one end of a magnet free to turn about its centre; its first use is ascribed to Sabine. The third type, due to Airy, is a polar curve, whose radius vector represents the horizontal component of the force to which the variation may be ascribed. On pp. 260, 261, and 262 are reproductions of vectorial curves by Airy, showing the mean diurnal variation at Greenwich for each of the years 1848 to 1857, with corresponding curves for Parc St. Maur for each of the years 1883 to 1897, and curves showing the mean diurnal variation at Parc St. Maur for each separate month of the year. The author points out that the mean annual Paris curves are all similar in type (though variable of course in area), whilst the Greenwich curves vary conspicuously in type.

A second instance of divergence between older and more recent observations is supplied by the *annual* variation of declination. This is the variation shown by the mean monthly values after allowance is made for a uniformly progressing secular variation. The *types* of this variation at Paris for the epochs 1821-30 and 1888-97 and at Kew for the epochs 1858-62 and 1890-94 are similar; but the *amplitudes* of the earlier and later epochs are respectively 129″ and 20″ at Paris and 120″ and 74″ at Kew.* We share the author's opinion that the question merits a critical examination.

Chapter XI. gives copies of some of Neumayer's world charts for the epoch 1885; they are, however, on a somewhat small scale compared to the copies of the English Admiralty charts included in Vol. II. of Adams's papers. Fig. 78 is an isogonal chart of France for 1896; though also on a small scale it shows very clearly the interesting anomaly in the Paris basin discovered by Moureaux. The description of the Gaussian analysis in Chapter XII. will probably be found ample except by the exceptional individual who desires to calculate Gaussian constants for a particular epoch. A convenient table on p. 352 gives the values found for the first order Gaussian constants at various epochs, with the corresponding co-ordinates of the northern end of the magnetic axis and the values of the moment of the so-called "normal" distribution. It may be worth mentioning† that the data ascribed to Adams are not those which he obtained when he limited himself like Gauss to 24 constants, also that the longitude of the end of the magnetic axis in 1880 as calculated from Adams' data is not 63°39′, as stated, but 68°4′. Article 184 refers to Schmidt's calculations of earth-air currents. The line integral of magnetic force round a parallel of (northern) latitude from west to east equals 4π times the total earth-air current (taken positively upwards) over the included portion of the northern hemisphere. The author (p. 371) describes the positive direction of the current as "from north to south," having in view presumably the return path in the atmosphere. Whilst regarding earth-air currents as not antecedently improbable—especially during aurora—the author regards their existence as not yet *demonstrated* by the established facts of terrestrial magnetism.

The discussion of atmospheric electricity in Chapter XIII. seems to attach considerable weight to Chauveau's recent theory that the diurnal variation of potential has normally but a single maximum and minimum, and that a double oscillation occurs only at low-level stations, and even there tends to become a single oscillation in winter. It also comments favourably on the ultra-violet light theory of the origin of atmospheric electricity, in view more especially of Buisson's recent experiments on electrified ice.

In treating of industrial currents (Article 146) the author calculates the magnetic force arising from two equal, but opposite, currents along infinite parallel wires close together. The magnetic force then diminishes as the inverse square of the distance. As the author, however, remarks, the result would lead to too optimistic views if applied to trolley lines. Owing to leakage, the currents in the wire and in the rails are unequal, leaving a considerable uncompensated current whose disturbing effect on magnetic instruments diminishes only as the inverse first power of the distance, whilst the action of the leakage currents is decided largely by local peculiarities.

The treatment of ships' magnetism in Chapter XIV. is exceptionally full, and the mathematical analysis is, in general, extremely neat.

As is almost invariably the case in the first edition of a comprehensive work, there are a considerable number of errata, especially in the later chapters. These are, however, mostly printer's errors of an obvious kind, and their enumeration would unduly occupy space. The numerical tables seem carefully compiled, if one may judge from a comparison of a good many of them with original sources, and the presentation of facts seems both clear and discriminating. The authors of some recent work, especially those fond of speculation, may feel somewhat neglected, but the policy of touching very lightly on hypotheses which are likely to undergo considerable transformation before general acceptance has a good deal to be said in its favour. One aspect of the book that should recommend it in this country is its full recognition of English work both ancient and modern. Whilst we have ventured on a few criticisms we regard the book as an excellent one, likely to enhance the author's long-established reputation. He is to be congratulated on the energy that has enabled him to compile and co-ordinate so successfully the multifarious facts of "Terrestrial Magnetism," notwithstanding the claims of the important official duties which he discharges.

CHARLES CHREE.

* Some of the amplitude data on p. 267 are incorrect, owing chiefly to the printer confusing seconds and decimals of a minute.

† We also differ in the coefficient of e^2 from the result obtained in Article 126, and from the formulæ in Article 133 for ϕ'_e, g'_e, h'_e, and F'_e. The *general* conclusions remain, however, unaffected.

PHOTOMETRY.*

BY J. VIOLLE.

The International Electrical Congress of Geneva, 1896, adopted the following resolutions with regard to photometric quantities and standards of light:—

1. The international photometric standards have for their basis the luminous intensity of a point source. They are embodied in the following table:—

Quantity.	Name.	Definition.
Intensity of light	Candle	I
Luminous flux	Lumen	$\Phi = I\Omega$
Illumination	Lux = Lumen/square metre.	$E = \Phi/s$
Brightness	Candles per square metre	$e = I/s$
Lighting	Lumen-hours	$Q = \Phi T$

2. The unit of intensity is the decimal candle.

3. Provisionally, the decimal candle may, for industrial purposes, be represented by the horizontal intensity of the Hefner lamp, subject to the necessary corrections.

* Abstract of a Report presented to the International Electricity Congress at Paris.

Incandescence Standards.

I. The international platinum standard has, notably at the Geneva Congress, been subject to criticism which appears hardly justified. Some time after the congress we enumerated the conditions which should be observed in using this standard. The platinum should be perfectly pure, and so should the lime of the crucible. In a work on the standards of light, which is of fundamental importance,* M. Petavel gives preference to the Violle standard, employed under the following conditions :—

1. The platinum must be chemically pure.
2. The crucible must be made of pure lime (prepared by calcination of the carbonate) obtained by precipitating calcium nitrate by ammonium carbonate.
3. The hydrogen burnt must not contain hydrocarbons.
4. The gases must be in the proportion of four volumes of hydrogen to three of oxygen, mixed by passing the oxygen both through an inner tube and through an annular space outside the hydrogen tube.

Under these conditions, the platinum is carried to a temperature little over the fusing point, and the luminosity of the metal is not altered by a combination with carbon.

The apparatus constructed by M. Petavel permits a single experimenter to conduct the whole operation. The expenditure of hydrogen being brought to 0·8 cubic ft. per minute, combustion is carried on for 15min. At the end of that time the two currents of gas are stopped by an electromagnetic device, and a diaphragm is placed over the platinum instead of the blow-pipe. After centreing the cover, measurements can begin. After another heating of 15min. readings are taken every 10sec., marked by a bell. The positions of the photometer index are marked, and subsequently read at leisure.

The luminous intensity falls very rapidly at first, then suddenly rises with a flash, and varies very slowly for 40sec. or 50sec., after which the fall is accelerated. M. Petavel enters the readings corresponding to the slow variation on squared paper. The points so obtained are sensibly on a straight line, and that line is produced up to the abscissa corresponding to the flash. The value thus found is called the intensity at the moment of solidification. The experimental error is about 1 per cent. at the most.

When the platinum is heated electrically, the lime crucible is rapidly deformed. It is therefore better to fuse the platinum in a nickel crucible kept cool by a current of water. The platinum remains solid where it touches the nickel, and the latter is not heated to redness at any point.

II. Messrs. Lummer and Kurlbaum propose to employ incandescent platinum at a temperature below that of fusion, and defined by the condition that nine-tenths of the energy radiated are to be absorbed by a layer of water 2cm. thick. In the apparatus used at the Reichsanstalt at Charlottenburg, the source is a sheet of platinum 25mm. broad and 0·015mm. thick, brought to incandescence by a current of about 80 amperes. The energy radiated is measured by a bolometer designed specially for this work. Though the author's method is a valuable application of physical precision to photometry, the employment of a shunted galvanometer introduces the risk of thermo-electric forces and other complications, and on account of the low temperature chosen, the light is too red for photometric purposes. Although, therefore, this modified platinum standard may serve as an intermediate standard, as for verifying the Hefner lamp, it is hardly available as an ultimate standard.

III. Another constant and very high temperature is given us in the crater of the positive arc carbon. Electricians have known for some time that the area of the crater varies nearly as the current intensity, and that the luminosity follows nearly the same law. I have shown that the brightness remains strictly constant when the power varies from 500 watts to 34,000 watts. This constancy shows that the temperature of the positive carbon is unchangeable, and confirms the old hypothesis of the volatilisation of the carbon in the arc. Messrs. Le Chatelier and Blondel have proved, on carbons of very different make, that the brightness is the same whatever their density or molecular state, so long as they are pure enough.

Utilising these results, M. Blondel has constructed an apparatus permitting the use of a known area of the crater as a source of light. Messrs. Abney, Swinburne and Silvanus Thompson had already endeavoured to base a secondary standard on the same principle, and I have made attempts in the same direction. These attempts have not yet furnished absolutely satisfactory results. One of the causes of the lack of success is the fact that when the arc hisses the most brilliant region is displaced periodically on the surface of the carbon ; and even when the arc is silent the immobility of the useful spot is not all that could be desired. M. Petavel, who also studied the positive carbon with a view towards its utilisation as a standard of light, did not succeed in obtaining perfectly concordant values for the brightness of the crater. The mean result was 147 c.p. per square millimetre, which is in fair agreement with the 158 found by Blondel. The confirmation of the essential result, viz., the constancy of the brightness of the most luminous part of the crater, justifies the hope that after all the positive carbon may furnish a practical standard. M. Petavel had already obtained more satisfactory results by arranging three negative carbons along the edges of a regular pyramid having the crater for its apex. He only abandoned this device owing to its complication, which did not allow him to observe by himself. The doubts produced by the extreme results obtained by M. Petavel are lessened by noticing with him that they are due to a difference of temperature between 3,935deg. and 4,018deg. It is reasonable to believe that further researches will narrow even this small interval.

IV. The study of incandescent lamps, apart from its practical importance, presents a great interest since their utilisation as intermediate standards in photometry. Numerous experiments have shown that these standards may be brought to a definite luminosity if the pressure at the terminals is carefully regulated. This regulation must be very precise, since the luminous intensity changes much more rapidly than the voltage (5·5 times, according to Liebenthal).

Constancy is not obtained in these standards except by using rays emitted in a direction in the neighbourhood of which the intensity does not vary much. The work of M. Liebenthal furnishes us a collection of precious documents for the study of the different forms of lamps in different directions. The author distinguishes four types of incandescent filaments : (1) The straight filament along the axis of the lamp. (2) The filament composed of two straight parts united by a curved portion which is a semi-circle, or slightly more than that (the filament may be simple or double, and the diameter of the curve larger or smaller in comparison with the total length).

3. The filament in which two rectilinear portions are joined by a curve whose projection on to the medial plane presents one, two, or three double points ; in the case of one double point the lamp may contain two similar filaments.

4. The filaments which describe round a left-handed curve semi-circular festoons whose plan is parallel to the axis of the lamp near the points of attachment, and normal to it in the middle portions.

The study of the horizontal intensity, by 40 measurements at intervals of 9deg. of circular measure, shows that reflections on the walls of the bulb, especially in type 3, may cause very considerable local anomalies. It is therefore necessary to choose a unique direction if we wish to calculate the mean horizontal intensity from a single determination. Experiment shows that, generally speaking, the intensity passes through a maximum in a direction perpendicular to the mean plane of the filament in types 2 and 3, and in the plane of symmetry in type 4.

The following coefficients enable one to find the mean horizontal intensity from that of the maximum :—

Type 2.	Straight parts close together..	0·99
„ 2.	Straight parts far apart, curved filament	0·88
„ 3.	Single loop between straight parts	0·94
„ 3.	Two or three loops	0·90
„ 4.	.....	0·73

Two measurements in mutually perpendicular directions do not as a rule give a satisfactory mean value. Three equidistant measurements might suffice, but the error may exceed 2 per cent.

An exact value of the mean horizontal intensity is always found by receiving the rays reflected by an unsilvered glass revolving about the axis of the lamp, with which it makes an angle of 45deg. This mirror might be replaced by a fixed pyramid of 10 glass plates.

The Union of German electricians has adopted as the horizontal intensity the mean of the intensities in three directions. The photometer receives the rays emanating directly from the lamp, and the rays reflected by two mirrors suitably inclined. The mean error amounts to 1·9 per cent. when the straight line joining the points of attachment of the filament is normal to the axis of the photometer.

M. Liebenthal concludes that the method recommended by the German Union for lamps without loops, or with a single loop, may be applied with sufficient approximation for practical purposes to other types, provided that the lamp to be tested and the standard lamp are of the same species and arranged as described. One may even employ the loopless lamps, which show a very constant distribution of intensity for standardising looped, filaments. Equality of intensity is not absolutely necessary ; a lamp of 10 c.p. or 25 c.p. may be compared with one of 16 c.p.

The American Institute of Electrical Engineers recommends, for determining the mean horizontal intensity, the method of turning the lamp upon its axis at the rate of two revolutions per second. That speed seems small enough to avoid the noxious effects of centrifugal force, and permits the application of the method proposed a long time ago by M. Crova.

M. Liebenthal's studies of the distribution of light outside the horizontal plane have shown him that the mean spherical intensity of the different types of incandescent lamp is equal to the mean intensity measured in a direction making an angle of 46deg. to 53deg. with the axis. This result is in good agreement with that of the committee of the American Electric Light Association. Mr. Bell, in his report, proposes to obtain the mean spherical intensity by observing the intensity of a lamp turning about an axis inclined 45deg. to the vertical.

Flame Standards.

The chief flame standards are: The Carcel lamp, prescribed in France for gas tests; the Vernon-Harcourt pentane lamp, employed in England in two forms, one of which now represents the English c.p.; and Von Hefner-Alteneck's amyl-acetate lamp, which is the legal standard in Germany, where it has replaced the Union paraffin candle.

The regulations for the use of the Carcel lamp continue to be applied as formulated by Dumas and Regnault. The Hefner and Vernon-Harcourt lamps have been, during these last years, the objects of important works, which we shall proceed to summarise.

I. The Hefner standard comprises a cylindrical receptacle and a wick tube of minutely regulated dimensions, together with a mechanism for regulating the height of the flame. The Reichsanstalt furnishes with every lamp a certificate of guarantee, setting forth that the dimensions are correctly observed, and giving the luminosities observed with the two wick-tubes and the two flame regulators supplied with each lamp. The height of the flame must be 60mm. A difference in the height, amounting to 1mm., produces a difference in the luminosity amounting to 3 per cent.

M. Liebenthal's researches show that the intensity of the Hefner lamp is, on the average, several per cent. greater in winter than in summer. This effect is chiefly due to water vapour. Allowing for this vapour in accordance with Liebenthal's formula, the error is reduced to 0·41 per cent. The effect of change of barometric pressure is not great, as it does not exceed 0·4 per cent. for a difference of pressure of 40mm.

If x is the number of litres of water vapour in 1 cubic metre of air, and x^1 the number of litres of CO_2, the intensity varies according to the formulæ,

$$y = 1{\cdot}049\ (1 - 0{\cdot}0053x).$$
$$y = 1{\cdot}012 - 0{\cdot}0072\ x^1.$$

The superior influence of the water vapour is due to its greater specific heat. Since a prolonged use of the lamp also reduces the proportion of oxygen to nitrogen, a further error is introduced, which may amount to 2 per cent. if 1 litre of oxygen is withdrawn from every cubic metre.

The red tint of the flame and its inferior luminosity are its great drawbacks. Moreover, the mobility of the flame often necessitates an assistant observer. Otherwise the lamp gives very consistent values.

In 1891 the author found the value of 1·026 decimal candles for the Hefner lamp. More recent measurements, undertaken by M. Laporte* at the Central Electrical Laboratory, with Hefner lamps properly standardised, gave the very different value of 0·885 decimal candles. This was based upon a Carcel lamp, whose value the author had found to be 9·6 decimal candles.

II. In the 1 c.p. pentane standard the liquid pentane contained in a recipient is evaporated by a wick placed inside a tube projecting beyond it by several centimetres, so that the wick is not charred. The flame burns in the open air; its upper part enters a chimney, which reduces its mobility and gives it a whiter tint. A small window gives a view of the point of the flame, which must be kept in the centre of the window. The intensity of the visible part of the flame, between the burner and the lower edge of the chimney, is then of the value of 1 English c.p. According to M. Vernon-Harcourt the flame is steady after a quarter of an hour, any further variations rarely attaining 2 per cent.

In another type, represented by the 10 c.p. lamp prescribed in England for gas testing, the lamp is fed by a current of air charged with pentane vapour in its passage through a saturator. The mixture descends, under the influence of its weight, through a caoutchouc tube into a ring-shaped steatite burner. The chimney is surrounded by a brass tube, in which an ascending current of air is produced, and this air is brought back to the base of the flame by a central tube. In a Paper read before the Institution of Gas Engineers in June, 1898, M. Vernon-Harcourt showed that the intensities of the two standards described do not differ by more than 1 per cent.

M. Liebenthal has subjected the pentane standard to a study similar to that carried out on the Hefner standard. He found that the height of the flame must be regulated exactly. When the point is in the middle of the window the intensity passes through a maximum. It diminishes by 2·5 per cent. or 2·1 per cent. when the point is at the bottom or at the top of the window respectively. The flame does not reach its maximum intensity till half-an-hour after lighting.

The pentane lamp, though having a much stiffer flame than the Hefner, requires more attention. The influence of moisture is sensibly the same as for the Hefner lamp. The pressure, however, produces a much greater effect, and is regulated by the formula

$$\Delta y = 0{\cdot}00049(b - 760)$$

according to which a change of pressure of 40mm. brings about a variation of 2 per cent. It is therefore necessary to allow for altitude above sea level. This is a grave fault, but for all that the superiority of the Hefner over the pentane lamp as a standard is not clearly proved.

III. Dibdin's apparatus, recommended by the report of the Photometric Committee, has been the object of a study by Mr. Grafton. In this apparatus, the air carburates itself by its passage through pentane in a reservoir forming the base of the apparatus. But the proportion of air and pentane varies with the temperature and moisture in the room.

On the other hand, Methven's standard with pentane carburator fed by coal gas, and with a diaphragm before the flame, has given very good results. Moisture and temperature would not produce variations beyond 0·5 per cent. But this figure must be accepted with caution.

IV. Various flame standards have recently been proposed, but have not yet been adopted in practice; notably acetylene standards.

In 1893, the Dutch Photometric Commission recommended the employment of a lamp of the Vernon-Harcourt type slightly modified, in which a mixture of nine parts benzine with 100 parts of ether should be burnt. The intensity was to be 1·48 English c.p.

By burning acetylene under a pressure of 30cm. of water in a burner which spreads it out into a broad thin sheet, the author obtained in 1895 a perfectly steady flame, whose intensity surpassed 100 c.p. for an expenditure of 58 litres per hour. The brightness is uniform over a large area. In the type constructed by M. Carpentier the acetylene enters by a small conical orifice, draws the necessary air along with it, penetrates into a narrow mixing tube, and issues through a batswing burner. The flame is enclosed in a box, one of the faces of which carries an iris diaphragm, while the other receives diaphragms with perforations calibrated in advance.

The flame is of remarkable whiteness. Spectro-photometric measurements have shown that in the whole range of the visible spectrum the acetylene light differs little from that of fused platinum. M. Fery burns acetylene at the end of a thermometer tube about 0·5mm. in diameter. The height of the flame varies from 5mm. to 35mm., when the consumption of gas increases from 1·25 litres to 6 litres per hour. Between 10mm. and 25mm. the intensity is sensibly a linear function of the height of the flame. The diameter of the flame varies very slightly.

The inconvenience presented by the combustion of acetylene of producing a deposit which obstructs the passage would be avoided, according to Blondel,* if pure ethylene were burnt in pure oxygen.

Another acetylene standard has been constructed in America by Mr. Fessenden. The Committee of the American Institution of Electrical Engineers burns a mixture of two parts of acetylene and one part of hydrogen in a current of pure oxygen.

M. Blondel has constructed a chimney lamp burning a mixture of alcohol and crystallisable benzine, and M. Broca has proposed an "albo-carbon" lamp burning naphthalene, which is supposed to give a very constant intensity.

V. The above descriptions show sufficiently clearly how difficult it is to obtain satisfactory results with flame standards. The greatest errors are due to variations in the height of the flames, which may amount to as much as 24 per cent. With a careful regulation of the height, the intensity of the Hefner lamp may be kept within 2 per cent. of its standard value. But the old Carcel lamp appears to be the steadiest of all, since with careful handling the error may be kept below 0·8 per cent.

Photometers.

I. The principle of Bunsen's photometer has been utilised by Messrs. Lummer and Brodhun for constructing an apparatus which is greatly superior to those which had preceded it. The opaque part of the screen is constituted by a portion of the hypothenuse face of a total-reflection prism, which throws back the rays coming from one of the sources. The middle region is, on the other hand, deprived of reflecting power by having another prism of equal refractivity pressed against it. The contact surface is circular, and lies in the plane of symmetry of the photometer. Two white screens, illuminated by the two sources, are seen side by side by the two alternative paths, and their equality is tested by the disappearance of the circle of contact. The great superiority of this photometer over the older forms lies in the sharpness of the dividing line between the two illuminated surfaces. When the two sources have slightly different tints, equality of brightness produces a continuous gradation which cannot be mistaken. A variation of 1·5 per cent. in the brightness of a source is distinctly traceable, and the mean error of a reading is less than 0·5 per cent. But an unexplained imperfection lies in the fact that when the two sources are reversed differences as high as 3 per cent. are often indicated. This may be due to some hitherto unknown peculiarity of "total" reflection.

The same apparatus may be employed if we adopt the principle of contrast instead of the principle of equality. Interposing in the half of each of the beams a plate of glass, four patches are obtained, and the distances may be so regulated that the contrast is the same in each pair. In the latest model, the field of vision is limited by an

Digitized by Google

elliptic curve with its longest axis vertical. To the right and left, trapezoid areas detach themselves, which, at the time of adjustment, must appear darker than the semi-ellipses which surround them, and the contrast must be the same.

II. MM. Blondel and Broca have constructed a univeral photometer which allows the performance of all the measurements required in photometry, such as intensity, luminosity, and brightness, both for near and distant sources. The apparatus is symmetrical, and carries two translucent diffusing screens which are binocularly observed by means of two mirrors at right angles to each other, and inclined at 45deg. to the rays. This part of the apparatus may take the place of a Bunsen or Violle photometer. Luminosity measurements are made as in Mascart's photometer. For intrinsic brightness, real images are produced on the screens, and the method of Cornu's microphotometer is followed.

III. M. Blondel's "photomesometer" applies the principle of Allard's method for determining the mean intensity, *i.e.*, the quantity

$$I_m = \tfrac{1}{2}\int_0^{\pi} I_a \sin a \, da.$$

where a is the angle between a fixed ray and a straight line which grazes the plane in which the observations are made.

M. Blondel sends the rays of the arc back to the photometer by means of a reflector formed by 24 mirrors arranged as a truncated regular pyramid. To measure the mean intensity, the arc is placed at the centre of a sphere provided with openings in the shape of windows bordered by meridians and subtending horizontal angles proportional to sin a. This sphere is made to turn at a rate of 200 revs. per min.

IV. In M. Blondel's luminometer the geometrical centre of the source to be studied coincides with the centre of figure of a sphere cut in two opposite directions along sectors of 18deg. each. The rays fall upon an ellipsoidal mirror which makes them converge on a diffusing screen. There they produce a luminous patch 20cm. to 50cm. in diameter, the intensity of which is determined by means of a photometer placed at a distance of 2m. to 5m. If the source is symmetrical a single reading suffices to determine the total luminous flux.

V. As regards colour photometry, it has been shown by Lummer and Murphy that there is no strict relation between the width of slit and the luminosity obtained in any region of the spectrum. Polychrome photometry is not facilitated, on the other hand, by reducing the intensities of the different colours, since the sensitiveness of the eye diminishes in the same proportion.

VI. The rotating sector, which is often used in spectrum photometry, does not give accurate results unless each flash of light has a duration of less than 0·01 second. This has been shown by Charpentier's investigation of the properties of the retina.

VII. MM. Lummer and Brodhun have constructed a spectrophotometer, in which the superposition of the rays proceeding from two collimators at right angles is effected by a system of two total-reflection prisms with vertical edges. The hypothenuse surfaces are plane as in the contrast photometer. On one of them the surface layer is removed along strips normal to the edge. Mr. Brace has since constructed a simpler apparatus on the same principle.

VIII. Colour photometry seems to have made considerable progress since the application of a method proposed by M. Charpentier and Mr. Rood. This method is based upon the fact that when two surfaces of different tints are alternately brought before the eye in rapid succession, a flickering sensation is produced until the intensities are adjusted to a certain ratio. The point thus attained might be used to define "equal intensities." Unfortunately, when the two intensities are then reduced or increased in the same ratio, the flickering often re-appears.

ELECTRIC FURNACES.*

BY M. KELLER.

The author takes as archetypes of all modern electric furnaces those of Siemens & Huntingdon and Moissan. The first of these consisted of a crucible of some refractory earth, receiving current at its base, a movable carbon pencil fixed within it acting as the second electrode. The arc was thus formed between the lower point of this carbon electrode and the surface of the materials contained within the crucible. The Moissan furnace consisted of a block of lime, hollowed out at its centre to receive the materials to be heated, and provided with horizontal channels for reception of the two carbon pencils conveying the current. A second block of lime, fitting over the first, completed this furnace, and served to retain the heat emitted by the arc which formed between the points of the two carbon pencils when the electric current was passed along them. The materials in this furnace were placed in the hollow cavity in the centre of the block and the arc played *over* their surface.

The first of the electric furnaces developed from the above laboratory types for industrial purposes was that of the brothers Cowles. In this furnace the material to be treated was placed between two conducting surfaces, which conveyed the current, and was surrounded by non-conducting finely-divided material. The current was thus obliged to traverse the material lying between the two electrodes, and if this in the unfused state was a non-conductor of electricity, movable carbon electrodes were used in order to form an arc above the furnace contents, and bring them to the fused condition. This furnace, invented in 1885, and improved in 1887, was used at Milton in Staffordshire for reduction of aluminium oxide, and for production of aluminium alloys.

The Héroult furnace introduced at a later date for obtaining alloys of aluminium with copper, was based upon the same principle as that of the Cowles brothers. This furnace has been used at Froges and at Neuhausen for production of aluminium, and more recently for the production of calcium carbide. The modified form adopted for the latter manufacture consists of a box mounted upon wheels, the base of which is of carbon, and the sides of some non-conducting material. The base of this box acts as one electrode, and a carbon rod, subject to a vertical up-and-down movement, forms the second. The furnace body is thus movable, and can be wheeled away when the reaction is completed, in order to be replaced by a newly-charged one.

The author next classifies the furnaces designed for calcium carbide manufacture as: (1) Arc furnaces (based on the Moissan and Siemens type); (2) Resistance furnaces (based on the Héroult type); (3) Incandescence furnaces (based on the Cowles type).

Arc furnaces may be again sub-divided into three classes, according to the mobility of one or both electrodes and the number of carbons used. The furnaces designed by Patin, by the Deutsche Gold und Silberscheide Anstalt, and by Street, have both electrodes movable, and thus come under sub-division I.

A very large number of furnaces fall into the second group, having one electrode fixed—generally as hearth or floor of the furnace. The furnaces exhibited by the Société des Carbures Métalliques at the Exhibition, and those designed by Siemens and Halske, Schuckert, and other well-known firms for carbide production, are of this type.

To the third sub-division belong all forms of the multiple arc furnace, which has lately become much used, because it enables the area of arc heating to be greatly extended. The Gin and Leleux, Bertolus, Memmo, Nicolai, and Bovy furnaces are leading examples of this type. In most of these furnaces the floor of the furnace acts as the common secondary electrode for the arcs which form between it and the three or more primary electrodes fixed around it. Polyphase currents are generally used with these furnaces.

In all arc furnaces the temperature attained varies with the intensity of the current used, but as in any case the temperature of the arc is very high and considerably above that required, loss of energy follows from arc heating in carbide production. There is also considerable loss of material, owing to the finer material charged being carried away by the "blowing" of the furnace. For these and other reasons arc furnaces are not suitable for carbide production.

Class II.—Resistance furnaces resemble in form and construction arc furnaces, but they work with a lower E.M.F., as the materials charged into the furnace body act as intermediate conductor between the two terminal carbons. The work done can be calculated by aid of the Joule formula $W = RI^2$, and the temperature attained is directly related to the sectional area of the electrodes. In this type of furnace the fusion of the materials is tranquil, and is unaccompanied by violent evolutions of gas. For carbide production an E.M.F. of 20 volts to 25 volts suffices, but heavier currents are requisite than with the arc furnaces, and conductors of larger sectional area must therefore be provided. The new furnace of the Compagnie Electrométallurgique des Procédés Gin and Leleux is of this type, and is employed in a large number of carbide works.

In the third class of furnace—incandescence furnaces—the intermediate conductor between the ends of the two electrodes is formed by a succession of small pieces of coke or other form of carbon. The passage of the current causes this bed of coke to attain a high temperature, and the materials placed upon it or mixed with it in their turn are raised to the same temperature. This type of furnace permits the utilisation within a limited area of the greatest amount of energy, and avoids the grave defect of the second type, namely, that the currents must always traverse the whole depth of the layer of materials already fused.

The author then passes on to consider electric furnaces under another classification, namely, that of the kind of current employed. Furnaces using continuous current have been sometimes called electrolytic furnaces, because in these not only thermal but chemical effects may be produced. Alternating current furnaces have latterly been widely adopted, because the dynamos yielding monophase or

* Abstract of a Paper read before the International Electricity Congress at Paris.

Digitized by Google

polyphase currents are better adapted to stand the resistance variations incidental to electric furnace operations.

The furnaces employing mono-phase currents are best arranged in series, for in this case it is possible to utilise a higher E.M.F. and to save copper in the necessary leads. If, however, arc-heating is being employed, it is better to connect the furnaces in parallel.

Bertolus, in 1897, was one of the first to patent the application of polyphase currents to furnace work. In the furnace designed by Bertolus tri-phase current was used, and three carbon electrodes were connected to the three terminals of the dynamo, while the hearth of the furnace itself provided the common return electrode. In later forms, the three different phases of the current have been utilised in separate furnaces, and these therefore each operate as though worked with mono-phase current.

Electrodes.—The difficulty of obtaining carbon electrodes of suitable size and length has for a long time hindered the increase of the size of the furnaces. Engineers have, however, given much attention to this question, which for the carbide industry is of considerable economic importance.

For those furnaces in which vertical electrodes are used, the carbon is generally formed square or rectangular in section, and undergoes special treatment in order to increase its conductivity, while for the other types of furnace carbons are usually made round.

In order to protect the carbon at the point where it entered the furnace, it was at one time customary to use water for cooling purposes, but this proved dangerous, and it has been given up for cold air, or some form of protecting composition.

Regulating the Electric Current.—In the modern forms of furnace for carbide production, working with relatively low E.M.F.s, it is usual to find currents of 8,000 amperes to 10,000 amperes employed. With such currents it is impossible to use ordinary cut-outs, and it is customary to make the movable electrode of the furnace act as circuit breaker. On account of the accidents which may occur to the dynamo, steam engine, or turbine, when a single furnace is worked in this manner on an electric circuit, it is advisable to work several furnaces in parallel from the one dynamo.

Current Pressure.—The E.M.F. required in arc furnaces varies greatly, and depends upon the conductivity of the gases which are emitted from the heated substances. In the manufacture of carbide of calcium, an E.M.F. of 50 volts to 60 volts is required, in that of corrundum 50 volts suffices, while the electro-thermal method for production of iron only requires 20 volts.

In resistance furnaces a lower E.M.F. is generally sufficient, and carbide of calcium can be manufactured in the Héroult type of furnace with a current of only 25 volts pressure. Aluminium can be produced in the same furnace with a pressure of from 20 volts to 25 volts.

The third type of furnace, "incandescence furnace," can work with practically any E.M.F. up to 80 volts or 100 volts, for the resistance increases with the increase of the length of the bed of materials through which the current has to pass, and this may be varied at will.

Current.—In the Cowles type of furnace currents of 5,000 amperes at 50 volts to 60 volts have been used. In the Héroult furnace currents of 6,000 amperes are used. For carbide production it is more customary to use currents of from 1,000 amperes to 2,500 amperes with single pairs of electrodes, but where several pairs of electrodes are used for arc heating in the same furnace, this current may be doubled, trebled, or quadrupled. Furnaces with a single arc, and one movable electrode are, however, now being worked with currents of 5,000 amperes to 6,000 amperes. The Gin and Leleux type of resistance furnace can be worked with currents up to 10,000 amperes, and the same amount of current can be utilised in the incandesence furnace, which, working with a higher E.M.F. than the resistance furnace is able to utilise for thermal purposes, no less than 1,000kw. electrical energy.

Developments of the Electric Furnace Industry.—Recent estimates have placed the total energy employed in electric furnace operations at 230,000 H.P., of which total, calcium carbide accounts for 185,000 H.P. aluminium for 27 000 H.P., copper for 11,000 H.P., and carborundum for 2,000 H.P. In France alone it is estimated that 60,000 H.P. are employed in the carbide manufacture; while the production of phosphorus, vanadium, and ferro-chromium are more recent thermo-chemical industries started in Savoy.

The improvements made in electric furnaces in recent years have resulted in a greatly improved output of carbide per kilowatt hour, and in the latest form of the Gin and Leleux furnace it is now possible to obtain 6·20kg. carbide per kilowatt day of 24 hours. This corresponds to a thermal efficiency of 75 per cent.

The Paper closes with a few details concerning the electric furnaces which are exhibited in the electro-chemical section of the exhibition. Three of these are shown in operation, and comprise a Moissan furnace, a Bullier furnace, and a small model of the Gin and Leleux type of furnace. The first consumes 40kw., and the second and third 70kw. electrical energy when in operation.

A COMBINATION INTEGRATING WATTMETER AND MAXIMUM DEMAND INDICATOR.*

BY JOHN H. BARKER.

This system has been at work for some years with marked success, but it has been necessary to use two separate meters—one to integrate the total number of units consumed, and the second to record the maximum demand; both meters absorb energy from the supply to the detriment of the light. In conjunction with Prof. Ewing the author has invented a meter which will combine the functions of the previous two. The maximum demand device can be attached to meters of the magnetic brake type, a prominent example of which is the meter sold by the Thomson-Houston Co. (Ltd.). The meter is essentially a motor and a magnetic brake; the latter consists of a copper disc revolving in a horizontal plane between the poles of the permanent magnets, the magnets set up eddy currents in the disc and produce a drag which is proportional to the speed of the rotation. In carrying out the invention this drag is made use of. The two magnets are supported on a beam and suspended in such a manner that they tend to follow the rotation of the disc. A steel wire enclosed within a tube is fixed at its upper end to a screw; at its lower extremity it is secured to the beam itself. The torsion of the steel wire acts as a spring and controls the distance through which the suspended system moves. The spring or other controlling force is made comparatively strong in order that the motion of the magnet poles may be so small as not to affect the rate of the meter, and also in order that the period of oscillation of the suspended system may be short. When a sudden increase takes place in the demand for current, and consequently in the rate of supply, the magnetic brake would tend to swing beyond the position proper to the new rate of supply if its period of oscillation were not short in relation to the time taken by the revolving parts of the meter to acquire their new velocity. This tendency is obviated by making the period of oscillation of the brake sufficiently short in relation to the time during which the disc is undergoing acceleration when the current is suddenly applied or suddenly increased. Further advantages of the strong controlling force, and consequently small movement of the brake, are that the brake may be pivotted eccentrically to the disc without causing its motion to affect the rate of the meter, and also that there is no necessity for the use of a dash-pot or similar arrangement to check the oscillations, although such means may be used if desired. Again, the small motion of the brake assists in preventing disturbance of the indications through the direct effect of the motor coils in cases where continuous currents are used, and the field of the motor is produced by current in coils. The motion of the brake is multiplied and actuates the indicator. A light ratchet and pawl is fixed at one end of the beam, and retains the system at its point of maximum deflection; a lever with a sealing device passes through the outside of the case, and enables the meter inspector to reset the indicator at the end of each quarter or half-year as the case may be. In meters for measuring supply by continuous currents, care must be taken to arrange the magnetic brake so that the electric currents in the meter do not directly tend to displace it. For this purpose it is preferable to invert one of the two magnets forming the brake, so that the pair shall constitute an astatic, or nearly astatic, system. When this is done it may in some cases occur that the stray field from the magnets constituting the brake affects the field of the motor, and consequently disturbs the rate of the meter. This may be compensated for by several devices, such as introducing a separate compensating magnet to balance on the motor armature, the field produced by the magnets of the brake, or using a shunt field coil in the motor for the same purpose. The scales for all sizes of meters are made the same, and the readings follow a straight line law; the divisions of the scale are given in percentages of full load of the meter, and a table is fixed to the front of each case, giving at a glance the maximum demand corresponding to any reading, as well as the number of units which must be consumed before the lower rate is charged. There is also a meter adapted for use on a switchboard; it integrates the amount of current which has passed through any feeder or from any dynamo, and informs the attendant the quantity passing through at any moment, obviating the use of an ammeter (more properly speaking a wattmeter). It differs from the ordinary meter, inasmuch as it has no ratchet and pawl, and is free to return to its zero position on the stoppage of current through the instrument.

There are many advantages claimed for this form of demand indicator: (*a*) It combines in one instrument the dual function of integrating and of recording the maximum demand; (*b*) as an indicator it absorbs no energy from the supply; (*c*) it contains no liquid or injurious acid; (*d*) it is not affected by any ordinary short circuit; (*e*) it records alternating or direct current; in the case of alternating current it records true watts and not apparent watts, an important item in respect of supply to motors and arc lamps; (*f*) it is

* Abstract of a Paper read before Section G of the British Association at Bradford, Sept. 10.

Digitized by Google

extremely accurate. Mr. Reginald P. Wilson some few years ago devised a maximum demand indicator embodying the same principle. The difficulty in this form was that the swing of the suspended system was sufficient to carry the pointer beyond its correct reading if a larger amount of current than a very small fraction of its full load were switched on at any one time, and the meter was never in commercial use. The inventors of the Barker and Ewing meter were unaware of Wilson's patent until their own was in its final form.

THE MANCHESTER AND LIVERPOOL EXPRESS RAILWAY.*

I.—BY SIR W. H. PREECE, F.R.S.

A mono-rail line has been projected by Mr. Behr between Manchester and Liverpool to accommodate express passenger traffic alone between those two cities. It is to be worked by electric traction, and to attain very high speeds. The train is to consist of only one coach weighing 45 tons and seating 64 passengers. Starting at every 10min., and travelling at the mean rate of 110 miles an hour, it will do the distance of 34½ miles in 20min. The fares will be slightly lower than those charged at present. There will be no intermediate stations, no points nor crossings. There will thus be no necessity for signals to protect the line during other operations. Signals would be needed only to secure a perfect block system of working the line. The mono-rail railway was projected by Lartigue in 1882. We have only one example of this system of railway in the United Kingdom, viz., between Listowel and Ballybunion, in County Kerry, Ireland. This line was designed and engineered by Mr. Behr. The act was obtained in 1887 and the line was opened for traffic in February, 1888, and it has been running ever since.

The line is 9¼ miles long. It has one intermediate station, Liselton. There are 42 level and farm crossings. It is worked by steam. The train consists of a locomotive and four coaches. It cost £33,000 to build, or £3,060 per mile. When I inspected the line in the early part of this year there had never been a Board of Trade enquiry into any accident. The maintenance of the structure had been effective. No rail had ever been turned. The mechanical structure had exhibited no defects, but several breakdowns had occurred in the locomotive and rolling stock. There are three locomotives, 11 passenger coaches, and two brake vans. They had, however, continued to work the line uninterruptedly for 12 years, and there had been no renewals or new stock. Its main principle is the suspension of the coaches on a single elevated rail so that their centres of gravity are below the rail. Each coach sits the rail like a saddle. The rail is fixed on trestles which are tied and braced together, the tie bars being light rails against which guide wheels roll.

The Manchester and Liverpool express is intended to be more massively and rigidly built. Derailment on such a structure is impossible, and curves of comparatively small radius can be passed with safety at high speeds. Vibrations and noise will be reduced and travelling will be conducted with greater comfort than at present. It is proposed to fix the generating station midway at Warrington, and to transmit the electric energy at high pressure (10,000) volts to each terminal station. There would be sub-stations along the line at distances apart of 4 miles, where the 10,000 volts would be brought down to 1,000 volts, at which pressure it would be picked up by the motors on the coach.

The speed which a train can acquire on a railway depends on the power that can be continuously applied at the tread of the driving wheel. Electricity enables the engineer to apply instantaneously to light loads a power which steam cannot supply. Hence speeds are possible with electricity which are unattainable with steam. A coach weighing 45 tons can easily and quickly attain 110 miles an hour. 1,600 H.P. will accelerate the coach so as to attain this speed in 110sec., and 500 H.P. will maintain this speed on the level. Electricity has two advantages over steam. It enables us to obtain an acceleration of 1½ft. per second, which is virtually the limit that can be obtained without causing discomfort to the passengers, and, secondly, it applies a continuous and constant torque instead of the variable one due to the reciprocating action of the ordinary steam locomotive. Hence it not only enables us to maintain high speeds on long through lines like the proposed Manchester and Liverpool Express, but it enables us to attain high speeds with greater rapidity on short lines having frequent stoppages, like the metropolitan railways of London, and thus increase the capacity of the line for traffic. The chief causes of accident on ordinary railways, viz., collision, derailmement, points, and the human error of the signalman will be removed from lines. Hence travelling will be much safer. Mr. Behr has prepared a short Paper on brakes and signals.

* Abstracts of two Papers read before Section G of the British Association at Bradford.

II.—BRAKES AND SIGNALS.

BY F. J. BEHR.

The question of brakes and signals are so intimately connected that the one cannot be treated separately from the other. The most perfect condition under which a railway could be worked, would be that in which both brakes and signals could be dispensed with, therefore it follows that the fewer the occasions for using either, the better.

Now as to brakes, there is a limitation of their application, which depends not so much on the mechanical appliances themselves as on the endurance of the human bodies in the trains. It was stated by an eminent railway official that with the Westinghouse brake, a train travelling at 60 miles an hour could be stopped, as an emergency brake, within 360 yards without inflicting too great a shock on the passengers. In the same way, a train travelling at 110 miles an hour could be stopped within 500 yards, and probably in a shorter distance, as in the latter case electrical means are at hand, such as the reversal of the motors, so as to turn them into dynamos. More rapid stoppage could only be made with great discomfort to the passengers. Now in the ordinary way of working our railways at present, there are many occasions in which it might be important to stop the train as rapidly as possible, for instance, if a train in front should be seen, or some shunting operations were not completed, or many others too many to enumerate; but no brake, however powerful, would be of the slightest use to-day to avoid a sudden obstacle, such as a stone placed on the rail, or a broken rail, for it is impossible for the driver to be aware of such obstacles until he is practically upon them. For these cases of great emergency, therefore, the stoppage at 300 yards, or 200 yards, or even 100 yards is quite useless.

What I wish to show now is that on the proposed high-speed electrical railways, though it is quite possible to brake the train within less than 500 yards, it never can be necessary to bring it to a standstill at even a much longer distance. On the proposed railway there are no level crossings, no switches, no shunting operations, and in fact nothing that will require the train to be brought to a standstill, except in the event that a preceding train should break down. Besides this one case, the brakes can only be used for stopping as you approach the stations. A broken rail offers no danger in this case whatever, for the train would run over it without any danger or difficulty. This can easily be shown by carefully considering the relative position of the wheels in the carriages to the rails over which they travel. I now, therefore, have only to explain the manner in which it is arranged that the driver of each train shall be informed of the possible stoppage of the train in front of him. No second train will leave the station at Manchester or Liverpool until the first has reached Warrington, a distance of just 17 miles. We sub-divide the line for the purpose of signalling into eight sections of 4·3 miles each. As trains leave Manchester station a danger signal is put up automatically at that station, a second similar danger signal is put up in the same way at 4·3 miles off, the first remaining at danger. The train travels on until it reaches 8·6 miles, when it puts up a third danger signal, and simultaneously the signal is lowered at Manchester or Liverpool station, so that the second train can leave when the time comes.

Now, we will assume that the first train has met with an accident after passing point 8·6 miles, the second train would travel at a higher speed right on, but when it passes point 4·3 miles, the danger signal at that point not having been removed by the first train, as this never reached point 13 miles, the driver of the second train would be informed that the first train had met with an accident beyond 8·6 miles, and therefore that he had to slow down, but that for such lowering of his speed he had a clear run of over 4 miles. Therefore, there could be no difficulty in any case to stop even without using the brake at all, by simply cutting off the current.

Whenever a train passes over a point where the danger signal is put up this is also produced, either electrically or mechanically, by a very simple and inexpensive contrivance in the cabin of the electrician, so that he should be perfectly able to see it without difficulty even if there was a thick fog. Under these conditions of travelling, it seems, therefore, superfluous to have any emergency brakes, and though we shall be able to stop the trains within 500 yards, no case can be imagined in which it would be useful or necessary to resort to such a stoppage. A 6-minute service of trains can be established without any alteration in the proposed arrangement, and if a 3-minute service was required, the blocks would have to be reduced to 2-mile sections, giving a clear run of 2 miles in case of a breakdown.

THE DESIGN AND LOCATION OF ELECTRIC GENERATING STATIONS.*

BY ALFRED H. GIBBINGS, M.INST.E.E.

The term "central station" is gradually being supplanted by more comprehensive designations. All design and arrangement in regard to electric works must be with a view to securing the highest *average* efficiency together with reliability in operation. Electric works at present do not fulfil these conditions, but that may excusably be accounted for, because it was impossible to foresee modern developments. Electricity, as first used for lighting only, has now come to be used in the form of electric motive power, and electric traction. The attempt to supply all these from one generating station, has led to the use of unsuitable plant, to confusion in the station itself, but at the same time to a reduction in prices charged. It has also resulted in a large variation in capital cost per kilowatt of plant. Small and isolated undertakings try to attain equally successful results by other experiments, but fail. Economical production is only possible where both the generating costs and the standing charges are reduced together as the load increases and the system extends. To effect this generating works must in future be constructed and located with a view to include the supply of energy for motive power, tramways, and electro-chemical purposes. Details of such construction and location should embody the following points:—(1) The machinery must be designed to generate at high voltage, differing according to the extent of the area and the nature of the system, but it must be suitable for transformation at sub-stations to meet all possible requirements. (2) The type of all boilers, engines, electric generators, switchboards, &c., must be simple and mechanically reliable even at the sacrifice of some slight maximum economy. (3) All complicated gear and fanciful combinations, such as might lead to possible breakdown, must be avoided throughout the entire arrangement. (4) As far as possible the different units of the respective types of plant should be uniform in design and arrangement and made to one standard size, thus economising in labour, avoiding large "stand-by" plant and spare gear. (5) The buildings should be devoid of all unnecessary embellishments, nor should an attempt be made to confine too many departments under one roof. (6) The location should be such as to ensure a cheap and ready supply and delivery of fuel, and where condensing can be accomplished efficiently and inexpensively.

THE USE OF MULTIPLE SPACE IN APPLIED MATHEMATICS.†

BY H. S. CARSLAW.

The ordinary method of images may be used in the solution of problems in electrostatics, &c., when the bounding planes meet at an angle, π/m, but it fails when the angle of inclination is $n\pi/m$ (n, m positive integers). Illustrations: π/m ($m=1, 2$); $n\pi/m$ ($m=1$, $n=2$: $m=2$, $n=3$). So far as I can learn it was first pointed out by Sommerfeld‡ that a Riemann's surface might be here employed, and with the help of a multiple space problems in electrostatics, electric conduction, hydrodynamics, sound, and conduction of heat, in which the boundaries are planes meeting at an angle, $n\pi/m$, have now been solved by images. The ideas involved may be illustrated by the potential problem in which the boundary is the semi-infinite plane $\theta=0$. There is nothing to prevent us assuming that in this case the space with which we have to deal is defined by the range of $0<\theta<2\pi$, and the behaviour of the solution of the equation $\nabla^2 u=0$, outside that range need not concern us. It is found§ that the periodic function

$$u=\frac{2}{\pi R}\tan^{-1}\sqrt{\frac{\sigma+r}{\sigma-r}},$$

where
$$R^2=r^2+r'^2-2rr'\cos(\theta-\theta')+(z-z')^2,$$
$$2rr'\cosh\alpha_1=r^2+r'^2+(z-z')^2,$$
$$\sigma=\cosh\alpha_1/2,$$
and $$r=\cos(\theta-\theta'/2),$$

is a solution of the equation $\nabla^2 u=0$, with the required properties, its only singularity, in the range $-2\pi<\theta<2\pi$, being at (r', θ', z'). Calling this the solution corresponding to a pole at (θ'), if we associate with it that due to a pole at $(-\theta')$, we obtain a function, satisfying the boundary conditions, with only the one singularity in the range with which we are concerned. Similar ideas enter into the solution of the other questions of this nature: where the ordinary image method would reproduce singularities in the original space, by taking a function of a suitable period (a Riemann's space of the proper order) this result is avoided. The problems in potential involving spherical boundaries may be solved by inversion from the above. Hobson has considered,* by discussion in series, the direct solution of the cases of the circular disc and spherical bowl. By a method similar to Sommerfeld's, I have found the solution for the general case. Taking the co-ordinate system employed by Hobson, in which the position of the point P is defined by $\rho=\log PA/PB$, $\theta=\angle APB$, $\phi=$azimuthal angle, the boundary $\theta=$constant, represents a portion of a spherical surface of which the rim of the circular disc, whose diameter is AB, is the base. If we are dealing with the space bounded by an infinite plane with a circular hole we define this region by $0<\theta<2\pi$, and associate with it that defined by $-2\pi<\theta<0$. Corresponding to the singularity at (θ'), we shall have one at $(-\theta')$.

When the boundary is the infinite plane with hemisperical bowl we consider our physical space as given by $0<\theta<3\pi/2$, and require three revolutions of the radius vector to complete our multiple space. The poles will now be at $(\pm\theta')$, $(\pm(3\pi+\theta'))$.

The general solution (of period $2n\pi$) required for such problems is given by

$$u=\frac{1}{n\pi\sqrt{2}}\sqrt{\cos h\rho-\cos\theta.\cos h\rho'-\cos\theta}\int_a^\infty\frac{1}{\sqrt{\cos ha-\cos h\alpha}}\frac{\sin h\frac{a}{n}}{\cos h\frac{a}{n}-\cos\frac{\theta-\theta'}{n}}da,$$

where $$\cos h\alpha=\cos h\rho\cos h\rho'-\sin h\rho\sin h\rho'\cos(\phi-\phi').$$

ON THE SIMILARITY OF EFFECT OF ELECTRICAL STIMULUS ON INORGANIC AND LIVING SUBSTANCES.†

BY PROF. J. CHUNDER BOSE, D.SC.

(*Continued from page 777*).

5. *Effect of Temperature in Hastening the Recovery.*—(*a*) I give below two curves which clearly show the effect of temperature in hastening the recovery. For the sensitive substance I took magnetic oxide of iron, Fe_3O_4. Curve (*a*), Fig. 5, represents the effect of Fe_3O_4 when *cold*. The increase of galvanometer deflection due to a single flash of radiation was 150 divisions; the after recovery was very slow, the deflection falling through only 30 divisions in 75sec; the rate of subsequent fall was still slower.‡

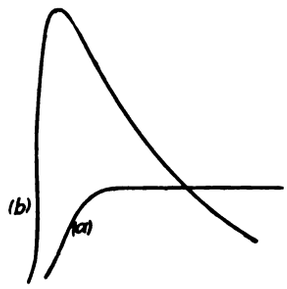

FIG. 5.—Effect of Temperature in hastening the Recovery.

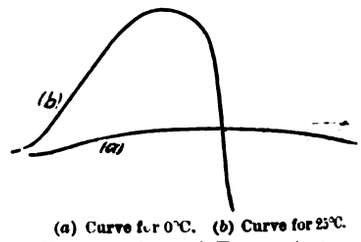

(*a*) Curve for 0°C. (*b*) Curve for 25°C.

FIG. 6.—Effect of Temperature on the Muscle Curve.

I now warmed the substance over 100°C.; the response was slight and the recovery also very feeble. I now allowed the temperature of the substance to fall very gradually, and took observations for intermediate temperatures. The curve (*b*) is for a temperature of about 15°C. above the temperature of the room. It will be noticed that the sensitiveness of the substance is very much increased; a flash of radiation now produced a deflection of 400 divisions, the sensitiveness having thus been increased nearly threefold. The recovery is rapid, especially in the first part of the fall, the substance recovering completely in 75sec.

It is thus seen that an increase of temperature up to a certain limit increases the sensibility and hastens the recovery, but beyond this limit the sensitiveness and the quickness of recovery are both diminished. A remarkable parallel to the above is seen in the influence of temperature on the muscles curve (see above).

§ *Proc.* Lond. Math. Soc., XXVIII., p. 413.

* *Trans.* Camb. Phil. Soc., Vol. XVIII.

† Paper read before Section A of the British Association at Bradford.

‡ The galvanometer used in these investigations is a dead-beat D'Arsonval; the natural time of return of the coil to equilibrium position is very quick. The sensitive substance was so chosen that the cycle of conductivity changes should occupy a comparatively long time—about two minutes.

Digitized by Google

It appears probable that for each sensitive substance there is an optimum temperature for which the sensitiveness is a maximum.

(*b*). In muscles the effects are exactly similar (see Fig. 6). Increase of temperature up to a certain limit is found to increase the response (the height of contraction) and hastens the recovery, but beyond this limit the contractions are lessened in height.

6. *Distortion beyond the Elastic Limit: Fatigue.*—It was mentioned that a substance is more or less permanently distorted by a stimulus (1) if the limit of electric elasticity of the substance is narrow, or (2) if the intensity of stimulus is very great. Imagine a substance so distorted. It was shown (see 2) that after a stimulus has produced the maximum effect on a sensitive substance, there is no further action on it by the superposition of a second stimulus, *unless the substance has meanwhile recovered from the state of strain.* In the case of overstrain there is no immediate recovery owing to molecular friction; hence there is no further action of stimulus on an overstrained substance; the latter is then said to be fatigued. Imagine a galvonometer needle violently deflected by a strong transient current sticking to the side of the coil and prevented by friction from returning to the equilibrium position. In the distorted and constrained position the needle responds no longer, gentle taps release the needle and the galvanometer is again made responsive. If we wish to remove the fatigue of the substance and make it responsive, we have to release the strained particles by vibration—by mechanical taps or by gentle application of heat. Now it is well known how tapping restores the sensitiveness of a molecular receiver. It has also been shown how a slight rise of temperature hastens the recovery, and is thus effective in the rapid removal of fatigue. I shall now pass into the consideration of muscular fatigue.

(*b*) In the muscles, the cause of fatigue is obscure and is generally ascribed to the breaking down of the "material necessary for contraction" and the accumulation of "fatigue stuffs." Fatigue is removed after a period of repose, and it is supposed that the blood supply repairs the disintegrated tissues and eliminates the products of dissimilation. "But if we cut off all communication of the muscles with its nutrient vessels bringing in blood, the muscle thus

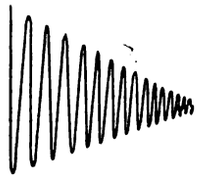

Fig. 7.—Typical Fatigue Curve of Inorganic Substances and Muscles.

reduced to the unassisted energy of its own elements will be able to pass through the alternate stages of exhaustion and to power of contraction under the influence of repose."* This shows that the primary cause of fatigue is not the accumulation of fatigue stuffs.

We have seen that in inorganic substances fatigue is due to overstrain, and that the substance recovers slowly after a period of repose, when it again becomes sensitive. It was also shown that in inorganic substances the recovery is hastened by mechanical vibration and gentle application of heat In the muscles, too, fatigue is quickly removed by mechanical vibration (massage), and the Turkish bath, which combines massage with gentle application of heat is, I believe, very effective in the quick removal of fatigue.

We must also remember that the muscles are bathed in an electrolytic medium, and certain volta-chemical action is induced as an after-effect of the strain. It is found that if two pieces of identical conducting substance are immersed in an electrolyte there is, of course, no E.M.F. between the two; but if one of them be subjected to any kind of strain, a difference of potential between the two is at once produced—a current flows from one to the other; one of the pieces will thus be dissolved (chemical combination) by the voltaic action. After this action has lasted for a considerable time, in order to maintain the efficiency of the voltaic cell it would be necessary to renovate the active plate and remove the products of chemical combination present in the electrolyte. If such an action due to unequal strain takes place in the living tissue, the regeneration of the acted tissue and the removal of chemical products may be effected by the blood supply. It will be noticed that the primary action is due to strain and the fatigue products are the secondary effects of the strain.

From what has been said above it is seen that when a sensitive inorganic substance or a muscle is subjected continuously to electric stimuli of even moderate intensity an increasing proportion of the molecule of the sensitive substance is gradually put in a state of strain, and the amplitudes of the successive response thus become smaller and smaller.

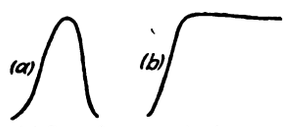
The accompanying diagrammatic curve (see Fig. 7) is typical of the fatigue curve of inorganic substances (*e.g.*, arsenic), and also of muscles.

Lagrange, "Physiology of Bodily Exercise," p. 174.

7. *Effect of Injection of Foreign Substances.*—(*a*) It has been said before that, owing probably to the mobility of its molecule, the recovery of potassium from the effect of stimulus is very rapid. If by any means, say by an admixture with a foreign substance, the viscosity is increased (or elasticity is decreased), then we may expect a retardation of recovery. I have been able to produce this retardation by mixing mercury with potassium. The nature of reaction to electric stimulus in the amalgam (a diminution of conductivity) remains the same as on pure potassium, but the power of self-recovery is lost.

(*b*) Apparently similar to the above is the effect of various "poisons" in modifying the form and time relations of the muscle curve. Thus, veratria (and also the barium, strontium, and calcium salts) retard the self-recovery of the muscle (see Fig. 9).

From the above series of phenomena, it will be seen how great is the resemblance between the effects of electric stimulus on inorganic substances and living tissues. Still more remarkable is the resemblance when we come to study the effect of radiation on the "sensitive substance" in the retina. The theory of molecular strain will then be found highly suggestive in an attempt to explain the complex phenomenon of visual impulse and other phenomena of



(*a*) Curve for pure potassium.

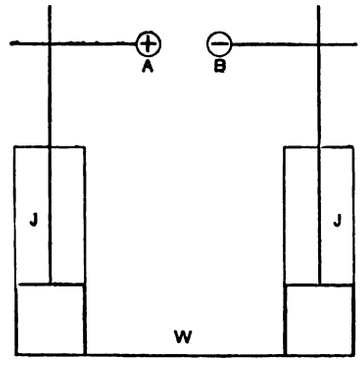
vision at present very obscure. In my next Paper I will give a brief sketch of the subject. A more complete treatment will be found in my communication to the Royal Society, of which the present Papers form an abstract.

(To be concluded.)

SPARK-LENGTH AS MODIFIED BY SOLID DIELECTRICS.*

BY W. J. HUMPHREYS.

While trying some experiments with an electrical influence machine I noticed that the spark-length was greatly increased by the presence of solid dielectrics, such as glass or ebonite, at certain



points near the positive pole. The phenomenon was entirely new to me, and as I was unable to find it described, or even mentioned, in either those books or journals to which one would go for such information I decided to publish an account of my observations. After my experiments were completed my attention was kindly directed to the fact that Messrs. Queen & Co., of Philadelphia, Pa., furnished an electrical influence machine with radically different poles—one being a metallic sphere while the other is a metal plate with an ebonite disc at its centre. I have also learned that Prof. Anthony once used a somewhat similar machine that was imported from Berlin about 1870. It seems, therefore, that the action of solid dielectrics on the spark-length has been known for a long while, at least to certain instrument makers, and I venture to publish the following account of my own experiments along this line because I have been unable, after considerable search and numerous inquiries, to find any reference in scientific literature to this interesting phenomenon.

During the course of the experiments several machines were tried and with equal success, but the one commonly used was a two-plate Wimshurst machine, the plates being 20in. in diameter, of ebonite and furnished with metallic sectors. The accompanying sketch

* From the *Physical Review.*

Digitized by Google

shows an arrangement that gives excellent results, though, as will appear from the experiments, it may be greatly modified and the phenomenon still obtained. J, J are two small Leyden jars, W a wire joining their outer coatings, A and B discharging balls connected one to the positive the other to the negative side of an influence machine or other source of high potential, and also to the inner coating of its respective jar. Let the inner coatings of the jars be oppositely charged, as indicated, and the distance between A and B gradually increased till sparks cease to pass. If now the potential difference be maintained and a glass rod, say, be placed quite near that side of the positive pole that faces the negative, the air will in general break down and allow a full noisy spark to pass. Nothing of the kind happens when the rod is placed next the negative pole, or in fact in any part of the field other than that very near the anode.

Various solid dielectrics have been used, all giving the same general result. Among them various kinds of glass, such as lead, soda and different varieties of enamel glass, some in the form of solid rods, others as tubes, even freshly drawn glass fibres of not over three-tenths of a millimeter in diameter, sticks of sulphur, rubber tubes, rods of ebonite, different varieties of wood and finally, as an extreme case, an ordinary silk thread stretched taut and approximately at right angles to the lines of force. The increase in spark-length was usually very pronounced, often more than doubling the maximum length obtainable under ordinary conditions.

In most of my experiments the machine was kept constantly running at an approximately uniform speed, but this was simply for the purpose of holding the potential difference as nearly constant as possible, and not at all essential to the general phenomenon. The sparks of extra length could easily be obtained after the machine had come to rest, provided they were taken before the potential had fallen too low. The following are among the conditions tested:—(1) Polished poles, jars belonging to machine and their outer coatings connected, inner coatings oppositely charged. Results excellent, best obtained. (2) Polished poles, jars belonging to machine but insulated from each other, inner coatings oppositely charged. Increase in spark-length decided, but volume of spark small. (3) Polished poles of machine oppositely charged, no jars. Increase in spark-length still evident, but volume of spark of course very small. (4) Polished poles, one connected to inner the other to outer coating of a single jar. Results good. (5) Polished poles, one or more jars of large capacity. Results pronounced, but spark-length never so long or so greatly increased as with the jars belonging to the machine. (6) State of atmosphere such as to give only very short sparks. Increase in spark length decided, but not very great. (7) State of atmosphere such as to give unusually long sparks. Increase in spark length not great, but still evident. (8) Poles separated very widely, beyond the length even of the forced spark. In this case a small spark left the positive pole when the glass or other dielectric rod was brought in proper position and disappeared along numerous little branches. (9) Negative pole polished, positive pole very rough, in fact the broken end of a metal rod. Under ordinary conditions this gave only pinkish brush discharges, except when the poles were very close together, when numerous small, white and somewhat noisy sparks passed. On placing a glass rod next the positive pole, the white and noisy sparks were more than doubled in size and length. Various other more or less important combinations were made, but these are sufficient to indicate the general nature of the phenomenon, the interpretation of which is probably the same, no matter what the conditions under which it is obtained.

Just what the correct or complete interpretation really is, I do not pretend to say, but the increase of the spark-length when the discharge is between two oppositely charged jars, insulated from each other seems to preclude the assumption that it can be due to oscillations of any kind. Possibly though an explanation is found in the fact that the solid dielectrics used in these experiments have specific inductive capacities greater than that of air, and consequently produced corresponding local concentrations of the lines of force, which concentration extended to a greater or less extent to the surface of the electrode when the dielectric was in its immediate neighbourhood. It may be that the increase in the spark-length was due to this local increase of the electromotive intensity, but in framing an hypothesis to explain it the fact that this increase must be next the anode has to be kept in mind. For the sake of binding these and other experiments more or less closely together, I suggest the following hypothesis: *The dielectric between two poles is most sensitive to electrical disturbances at points next the anode.* The following are some of the facts that seem to support this idea. (*a*) The spark-length is increased by the presence of a glass rod say next the anode, but not affected when the rod is in any other part of the field. (*b*) The greater the increase of the spark-length the nearer the glass rod must be brought to the positive pole. (*c*) The greatest increase of spark-length is obtained with a glass rod of certain size, other things being equal. That is, the rod must not be either too large or too small for best results. (*d*) When glass fibres are used they must be brought very near the pole, usually nearly or quite in contact with it. (*e*) The same phenomenon follows when insulated conductors are used instead of glass or other dielectric. With the view of testing this idea I tried, among other things, the effects of dielectrics of widely different inductive capacities, but otherwise approximately equal. The substances used were: (*a*) A small thin-walled test-tube, empty. (*b*) Similar tube part filled with water. (*c*) Similar tube part filled with metal. The results were not conclusive, the increase in the spark-length remaining nearly the same, with, if anything, the advantage in favour of the tube part filled with water, but this was not sufficiently pronounced to warrant deductions. Again the fact that insulated metal rods act no better than glass rods does not seem to be fully in accordance with the above assumption. These, however, are the only experimental objections I am aware of, and it may be that they are by no means fatal. In further support of this hypothesis we have the increase of spark-length caused by a small spark drawn from the negative pole of two oppositely-charged Leyden jars when their outer coatings are connected, and also Faraday's experiments on spark-lengths between spherical electrodes of different sizes. In speaking of these experiments of Faraday, J. J. Thomson says: "We may express this result by saying that when the electric field is not uniform the gas does not break down so easily when the greatest electromotive intensity is at the cathode as it does when it is at the anode." It will be noticed that the hypothesis used to explain these experiments is only an adaptation of this sentence of Thomson's. Whatever the real action of solid dielectrics in increasing spark-length may be, it is a phenomenon of the anode, and to that extent indicates a greater sensitiveness of the air about this pole to electrical disturbances. It would be interesting, but probably of little use at present, to speculate on the cause of this localised sensitiveness in the dielectric. Possibly it is due to the formation of Grothus' chains and the clustering of different types of ions about the two poles.

ELECTRICITY VERSUS GAS FOR TRAIN LIGHTING.*

BY ALTON D. ADAMS.

Railway trains seem to be about the last important structures, where power is available, that have not generally adopted the electric light. This fact is not only to the disadvantage of the public, as to quality of service, but also to that of railway companies in the matter of operating expense. Three methods of lighting railway cars are in use, those with oil and gas, very generally, and the electric in a few cases. This condition as to the illumination of railway trains is just about that which existed in large offices, mercantile and factory buildings some 15 years ago. Since that time there has been a wide and rapid change to electric light in a large part of such buildings, and the process is still going on. While the superior qualities of electric light have been factors in its application, the actual saving in the cost of operation, over other forms of illumination, has had much to do with its very general adoption in large buildings having power plants. It seems that the advantages of electric lighting that have enabled it to displace oil and gas lamps in large buildings must ultimately bring about a like result on railway trains. So far as the public is concerned, the superior quality of electric illumination is sufficient to give it a decided preference, and its greater safety and economy should appeal to railway managers. Oil is so generally conceded to be an inferior agent for illumination, and its use in railway cars has proved so destructive to life and property, through fire, at times of accident, that a comparison between gas and electric lighting should determine the most desirable method. On the score of safety from fire, gas represents a great advance over the oil lamp, since in case of accident to a car the gas does not spread flames as quickly and the supply is more easily shut off.

Electric lighting on railway trains represents a greater advance over gas, as to immunity from fire, than does gas over the oil lamp. When a railway car, lighted by gas, is overturned, it is highly probable that the gas flames will set it on fire. If an electrically lighted car is subjected to like usage, it is most probable that it will not be set on fire. To simply overturn an electrically lighted car would have no tendency to start a fire from the lamps, and even were the car broken or crushed so as to destroy the insulation on parts of the wires, the usual result would be to blow a fuse and a fire would not probably result once in 100 times. In those cases where the electric current is derived from machinery located at some one point in a train, a derailment would be apt to break the electrical connections between cars and thus shut off the supply.

Turning from the rather remote case of accidents to the ever-present costs of operation, the electric light can be shown to be decidedly cheaper than that from gas on railway trains. Some idea of the relative costs of the gas and electric lighting systems may be gained from the materials consumed for a given lighting effect by each. The costs of operation for electric train lighting vary somewhat according to the system used. Storage batteries are the most

* From the *Western Electrician* of Chicago.

Digitized by Google

expensive means for train lighting, not so much on account of the losses of energy in the batteries, which amount to about 15 per cent. of the energy sent into them, as from the items of interest, depreciation, labour and repairs. If electric lighting is to be generally adopted on steam-railway trains, it seems clear that the energy must be generated by dynamos on board, as this plan is at once the simplest and cheapest. With electric current generated by dynamos on the train, conditions approach very close to those that obtain in the ordinary isolated plant.

One of the most important points to be decided for electric-generating plants on railway trains is the method of driving the dynamo. Three plans for dynamo driving present themselves. Dynamos may be driven by steam from the locomotive boiler, used in a special engine ; a gasoline or oil engine may be operated for the dynamo, or it may take its power from the car axle.

Two material objections exist to the supply of power for the dynamo from the locomotive boiler ; one, that the available capacity of the boiler for hauling the train is thereby reduced, and the other and more serious objection that the dynamo can only be operated while the locomotive is connected with the train. That the reduction in the capacity of boiler available for train hauling is a small matter, may be seen from the requirements of power for lighting purposes. Allowing 30 incandescent lamps per car, each lamp consuming 50 watts, a train of 10 coaches would consume 15kw., or 20 E.H.P., with all lamps lighted. A good engine and dynamo, with capacity for this load, will show a combined efficiency of 80 per cent., as to the indicated power of the engine cylinder, and a simple engine for the purpose should not consume more than 30lb. of steam per indicated horse-power-hour at full load. The maximum demand for steam on the locomotive boiler should not, therefore, exceed $(20 \div 0{\cdot}80)\ 30 = 750$lb. per hour for electric lighting under the conditions stated. So small a per cent. of the locomotive capacity devoted to lighting purposes would not be objectionable in many cases, but might not be admissible in others. From the standpoint of lighting requirements, the necessity for locomotive connection before the dynamo can be operated is certainly objectionable, and turns attention to a system that is free from this defect.

The use of a special steam boiler on the baggage car for the purpose of electric lighting does not seem desirable, but a gasoline or oil engine may well be employed instead of a steam engine for dynamo driving. Petroleum engines, in the sizes suited for driving dynamos on railway trains, and working at from one-half to full load, may be expected to develop an indicated horse-power-hour on 0·8lb. of petroleum, or 0·6lb. of gasoline. Because of the explosive nature of gasoline vapour the petroleum is perhaps more desirable for use on railway trains. Allowing the petroleum engine and its driven dynamo to have a combined mechanical and electrical efficiency of 80 per cent., 1lb. of petroleum is consumed for each electrical horse-power-hour delivered at the dynamo terminals. Each electrical horse-power of 746 watts is sufficient to operate 15 50-watt incandescent lamps, so that the 300 lamps assumed to be necessary for a train of 10 coaches would require $300 \div 15 = 20$lb. of petroleum per hour of operation at full load. This includes no wiring or battery loss. A petroleum engine and dynamo in the baggage car would enable electric lamps to be operated in any part of the train as soon as it was made up, without regard to the presence of the locomotive.

Another method of driving dynamos on railway trains is that by which they are attached to the car axle. This plan combines the disadvantage incident to the reduced capacity of the locomotive for traction purposes, with the further one that when the train stops or has its speed reduced below a certain rate the dynamo is put out of action. In order to compensate for variations in the train speed, within certain limits, the dynamo must be of a special type, more expensive than the usual form. It seems doubtful whether any material advantage exists with a special dynamo driven by the car axle, over one with an independent engine, supplied with steam from the locomotive boiler. In order to render satisfactory lighting service, a storage battery is absolutely necessary on railway cars, where the dynamo is driven by the car axle, as the lamps must not go out when the train slows up or stops. With either a steam or petroleum engine to furnish power for the dynamo, a battery is only necessary if electric light must be had on the individual cars before they are connected with the baggage car. More battery capacity must obviously be had with a dynamo driven by the car axle than when an independent steam or petroleum engine is employed. In either case, however, the capacity of batteries is trifling compared with that necessary to light cars without the aid of a dynamo on the train. On the basis of the above figures, there must be $30 \div 0{\cdot}8 = 37{\cdot}5$lb. of steam taken from a locomotive boiler for each electrical horse-power-hour delivered at the dynamo terminals. Assuming a loss of 10 per cent., which is ample, in the car wiring, and in the auxiliary batteries, the delivery of 1 E.H.P. hour at the car lamps requires $37{\cdot}5 \div 0{\cdot}9 = 41{\cdot}6$lb. of steam from the locomotive boiler for the dynamo engine.

If the dynamo for train lighting is driven from the car axle, it seems certain that its requirement as to increase of steam in the locomotive cylinders will be at least the amount just stated. If the locomotive boiler evaporates 7lb. of water per pound of coal burned, 1 E.H.P. hour, delivered at lamp terminals, requires the consumption of $41{\cdot}6 \div 7 = 6$lb. of coal. Allowing the same loss of 10 per cent. in wiring and batteries, when a petroleum engine is used, each electrical horse-power delivered to the lamps require 1·1lb. of petroleum in the engine. As incandescent lamps of the 50-watt, or other usual size, yield one-third of a candle-power per watt, 6lb. of coal or 1·1lb. of petroleum furnish, through the agency of engine and dynamo, $746 \div 3 = 248$ c.p. hours. One thousand cubic feet of oil gas for car lighting can be produced from about 99lb. of petroleum and 96lb. of coal. This oil gas yields about 12 c.p. hours per cubic foot, in open-flame burners, or 12,000 candle hours for the 1,000 cubic ft. As the petroleum consumed to produce this 1,000 cubic ft. of oil gas is 90 times as much as that necessary to supply 1 E.H.P. hour to incandescent lamps, and the consumed coal is 16 times as great in amount, the petroleum and gas would generate $248 \times 106 = 26{,}288$ c.p. hours at electric lamps. This is more than twice the amount of light derived from this fuel when employed to generate oil gas.

The plant for oil gas production and the car equipments for its use cost probably somewhat less than do engines, dynamos, batteries and wiring for equivalent illumination, but the large saving in materials consumed, by the electric system, much more than offsets the greater first cost.

ON THE VECTOR POTENTIAL OF ELECTRIC CURRENTS IN A FIELD WHERE DISTURBANCES ARE PROPAGATED WITH FINITE VELOCITY.*

BY S. H. BURBURY, F.R.S.

1. If $u'v'w'$ be the components of the total electric current at $x'y'z$ in a homogeneous isotropic transparent medium, the components of vector potential FGH at any point xyz at a given instant are usually defined as follows :—

$$F = \iiint \frac{u'}{r}\,dx'dy'dz = \int \frac{u'}{r}\,d\tau, \text{ \&c.,}$$

where $$r = \sqrt{(x'-x)^2 + (y'-y)^2 + (z'-z)^2},$$

and the integration is over all space. Also $u'v'w'$ are the values of $u'v'w'$ at the given instant, and therefore all at the same instant. Hence follow Poisson's equations :—

$$\nabla^2 F_{xyz} = -4\pi u_{xyz}, \text{ \&c.} \quad \ldots\ldots\ldots \quad (1)$$

2. If

$$\begin{aligned} \alpha &= dH/dy - dG/dz \\ \beta &= dF/dz - dH/dx \\ \gamma &= dG/dx - dF/dy. \end{aligned} \quad \ldots\ldots\ldots \quad (2)$$

Then

$$d\gamma/dy - d\beta/dz = -\nabla^2 F + d/dx(dF/dx + dG/dy + dH/dz),$$

and if we assume

$$du'/dx + dv'/dy + dw'/dz = 0,$$

and therefore

$$dF/dx + dG/dy + dH/dz = 0 \text{ everywhere,}$$

we have

$$d\gamma/dy - d\beta/dz = -\nabla^2 F = 4\pi u. \quad \ldots\ldots\ldots \quad (3)$$

Hence is deduced

$$\nabla^2 F = K d^2 F/4\pi dt^2. \quad \ldots\ldots \quad (4)$$

where $V = 1/\sqrt{K}$ is the velocity of propagation of a disturbance. Also $\frac{1}{2}(Fu + Gv + Hw)$ is the energy per unit of volume at xyz. (5)

3. The theory in this form is open to objection. If u', the current at $x'y'z$, changes with the time, we have a corresponding change of F given by $dF/du' = 1/r$. But owing to (4) no physical quantity at xyz can be immediately affected by the change at $x'y'z$. The change can have no effect whatever at xyz till after the expiration of the time r/V. If therefore F be any physical quantity, we must have $dF/du' = 0$, which is inconsistent with our definition. If F be not a physical quantity, Fu cannot denote energy, which is inconsistent with (5).

4. The fact that V is very great, and r/V very small, does not meet the difficulty, because $\frac{r}{V}\frac{du'}{dt}$ is not generally small.

5. It is proposed to substitute for u', the current at $x'y'z'$ at the given instant u'_t, the current which did exist at $x'y'z'$ $\frac{r}{V}$ seconds ago, so that our definition will be $F_t = \int \frac{u'_t}{r}\,d\tau$. F_t is used by way of distinction from F. In this form of F the objections above taken cease to have effect.

As u' and all its derived coefficients according to the time are

* Abstract of a Paper read before Section A of the British Association at Bradford.

Digitized by Google

supposed finite, we may write $u'_t = u' - \frac{r}{V}\frac{du'}{dt} + \frac{1}{2}\frac{r^2}{V^2}\frac{d^2u'}{dt^2}$, &c., or symbolically, for convenience only.

$$u'_t = \epsilon^{-\frac{r}{V}\frac{d}{dt}}u'$$

$$F_t = \int dr \frac{1}{r}\epsilon^{-\frac{r}{V}\frac{d}{dt}}u' \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

6. It is shown that, *prima facie*, F_t, G_t, H_t, so defined, satisfy the differential equations (1) as well as do the ordinary FGH. So as regards the differential equations the proposed substitution makes no difference in form to the theory.

7. An objection is considered that F and F_t cannot both satisfy Poisson's equations (1) because if they did we should have $\nabla^2 F = \nabla^2 F_t$, and this cannot, it is said, be true because

$$F = F_t + \int dt \frac{1}{V}\frac{du'}{dt} - \frac{1}{2}\int dt \frac{r}{V^2}\frac{d^2u'}{dt^2} + \frac{1}{2\,3}\int dt \frac{r^2}{V^3}\frac{d^3u'}{dt^3}, \text{ &c.}$$

and since $\left.\begin{matrix}\nabla^2 r^2 = 0\\ \nabla^2 r = 0\end{matrix}\right\}$ when $r = 0, \nabla^2 F = \nabla^2 F$ is not true.

If the objection be valid, it is not evident whether we should use F or F_t.

8. But Poisson's equation requires only that, however small be the radius "a" of a sphere described about xyz.

$$\int_o^a 4\pi r^2 \nabla^2 F dr = -4\pi \int_o^a 4\pi_1{}^2 u dr,$$

and that is satisfied by both F and F_t. For the purpose of Poisson's equation we may use $\nabla^2 F$ and $\nabla^2 F_t$ as interchangeable.

9. Since du'/dt has different values for different waves, F_t should be the sum of a number of terms of the form (6), each corresponding to a wave-length.

10, *et seq.*—A calculation is made of the effect of using F_t instead of F in case of a disturbance spreading in spherical waves from a source.

CORRESPONDENCE.

ELECTROLYSIS BY TRACTION CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to your suggestion in your last issue of an underground insulated return connected permanently to a series of surface contact studs on the track, I think you may be interested to learn that Sir W. H. Preece and I applied in July last for a patent covering this modification of the surface-contact system, and that our application has been accepted.—Yours, &c., P. CARDEW.

London, S.W., Sept. 24.

CARBON FILAMENTS AND LIGHTNING FLASHES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I was very much interested in reading the editorial note in *The Electrician* of August 31 on the curious phenomenon observed in lighted glow lamps connected on the circuits of the Calcutta Electric Supply Co. I have had a long and extensive experience with incandescent lighting in this country, and have once or twice witnessed the phenomenon referred to. Each time it occurred simultaneously with an exceptionally vivid lightning flash, and in lamps connected with an overhead system of conductors. I have never before seen any printed account of this remarkable effect, and believe it to be an exceedingly rare occurrence over here.

It would be interesting to ascertain if the increased luminescence is due to the "coherer" effect, so ingeniously suggested in your note, or to an actual increase of line voltage, caused in some way by the atmospheric discharge.—Yours, &c., W. S. ANDREWS.

Schenectady, N.Y., U.S.A., Sept. 11.

[An unsigned letter on the above subject also appears in our Notes columns this week.—ED. *E.*]

Electric Tramway Working in New York.—The annual report of the Metropolitan Street Railway Co. of New York indicates a prosperous year's work and amply justifies the conversion from cable to electric traction. This conversion has been largely completed for some time, and the entire 217 miles of route will shortly be running on the conduit system. During the past year no less than 382,000,000 passengers were carried, the gross receipts being £2,944,000. The ratio of expenses to receipts was as low as 48·26 per cent.

MUNICIPAL, FOREIGN & GENERAL NOTES.

Arbroath.—A special meeting of the Gas Corporation was held on Tuesday to consider a report from the consulting engineers (Messrs. Mathew Buchau and Hogarth) on electric lighting. Further consideration was adjourned.

Barnes (London)—A loan of £30,900 for electricity works has been obtained from the Liverpool Victoria Legal Friendly Society at 3½ per cent.

Barnsley.—The borough electrical engineer (Mr. S. E. Bastow) has been instructed to prepare specifications and to invite tenders for a steam dynamo for the 1901 winter load. Fifteen additional enclosed arc lamps are to be erected.

Barnstaple.—Mr. W. P. Adams has been appointed consulting engineer to report upon electric lighting matters.

Bath.—The Electric Lighting committee reported on Tuesday that since the last meeting the equivalent of 1,800 8 c.p. lamps additional had been connected and 1,200 more were being connected.

Birstall (Yorks.).—The Council is considering the question of applying for electric lighting powers.

Bournemouth.—In addition to deciding upon applying for powers to borrow £200,000 for electric tramways, the Council have decided to open negotiations with the Bournemouth and Poole Electricity Supply Co. for the purchase of the company's works.

Brighouse.—Owing to the increasing demand for electric current the borough electrical engineer (Mr. J. W. Garside) has been authorised to refuse applications from new consumers until extensions to the plant are made.

Bristol.—The Electrical committee reported on Friday that serious differences of opinion had arisen between the engineer and the architect with regard to the foundations for the proposed electricity station at Avonbank. The points in dispute were of an important and complicated nature, and the committee recommended that the matters in dispute be submitted to Sir Benjamin Baker for advice. The recommendation was agreed to.

Buxton.—Application is to be made for powers to borrow £25,000 for electric lighting extensions.

Cannock.—Application is to be made by the Council for a provisional order.

Cardiff.—The dispute between the members of the staff of the electric lighting department was again under discussion by the Electric Lighting committee last week. The chairman (Ald. P. W. Carey) stated, in answer to a question by Mr. Good, that the committee had instructed the town clerk to report to the Board of Trade, and no doubt the Board would hold an inquiry. He had before him a long communication from Mr. Illingworth, which he had not read, but had only seen the signature, and he would have it sealed, with their permission. There were other questions to come on connected with the department which had better be discussed at a special meeting. Mr. Illingworth's letter was sealed, and a special meeting was held yesterday (Thursday) to further consider the matter.

Carmarthen.—A committee was appointed on Tuesday to report on the question of obtaining electric lighting powers.

Chapel Lighting.—The nave of St. George's Chapel, Windsor Castle, has been fitted for the electric light.

Croydon.—The County Council have applied for sanction to borrow £3,000 for arc lighting the tramway routes.

Dundalk.—The Council recently invited tenders for the transfer of their provisional electric lighting order, but we learn that no tender was received. Dundalk is a town of about 12,500 inhabitants, and the Council's provisional order was obtained in 1897.

Dundee.—By permission of the Board of Trade the speed of the electric tramcars in the centre of the city is to be increased from 4 miles to 6 miles per hour.

Electrical Enterprise in Mexico.—Electricity is being largely adopted in the development of the industries of Mexico. In the Pachaca district it is extensively employed in mining, water-power generation being established at a considerable distance from the point of distribution. For the lighting of the chief cities of Mexico electricity has been for some time adopted, and the imports of electric incandescent lamps in 1899 reached a total value of £15,899. These lamps were chiefly of American and German make; 100 tons of storage batteries, valued at £9,372, were imported into Mexico in 1899, chiefly from the States; 105 tons of rubber belting and 76½ tons of leather belting, the whole valued at £28,000, were imported.

Digitized by Google

The city of Tampico is lighted electrically, and the company owning the concession is now supplying current for private lighting. The Customs House and wharf are being lighted electrically, and the government is erecting its own supply station. The Customs House at Tampico is one of the finest buildings on the American continent.

At Monterey, a mining, smelting and manufacturing centre of growing importance, a project is on foot for the conversion of the street tramways from animal to electric traction. There is a suburban railroad running from Monterey to Topo Chico Hot Springs and the motive power is to be changed from animal to electric traction. The Monterey Electric Light Co. has considerably increased its plant and now supplies current for heating, cooking and motive power. The engine and boiler capacity was increased during 1899 from 300 H.P. to 750 H.P., and the station has a lamp connection of 7,800 16 c.p. A report on the trade of Mexico for 1899, from the British Consul, Mr. L. J. Jerome, should be read by all interested in Mexican trade developments.

Electric Lighting in Argentina.—It will be remembered that for some time past friction has existed between the Municipality of Rosario and the River Plate Electric Light and Traction Co. The matters in dispute were referred to arbitration. The *Review of the River Plate* for Sept. 1 announces that the Arbitration Court, which has been sitting for the past two years in the case of the Municipality of Rosario *v.* River Plate Electric Light Co. for non-fulfilment of contract, and the counterclaim of the company against the Municipality for fines unjustly imposed, has given its award. The company is ordered to put all its overhead wires, posts, &c., into proper order, and to comply with the rules of the English Board of Trade within six months; also to change all existing arc lamps for others of more modern construction, and to change the carbons at present being used. This is also to be done within six months. Any work not done within this time can be taken down by the Municipality and fines imposed for every lamp removed or not lighted at the rate of $1 gold a night. There are about 300 street lamps. Both parties are ordered to draw up regulations for interpretation of certain clauses in the contract within two months, failing which it is to be done by arbitration. The Municipality is ordered to listen to the protests of the company and to carry out the necessary tests before a fine can be imposed. Regulations for carrying out tests are also laid down. The claim of the Municipality for a return of about $200,000 for defective light and non-compliance with contract was thrown out. The counterclaim of the company for the return of fines was allowed in those cases in which it had been proved that these had been unjustly imposed. We learn, however, that nothing is known of this award at the London offices of the River Plate Company.

Electric Traction in Ceylon.—A proposal is made for the adoption of electric traction on the Uda Pussellawa Railway, and in a recent communication to the Colonial Secretary, the governor (Sir J. West Ridgeway) states that when travelling in England some time ago he had made himself acquainted with the working of the Isle of Man electric railway, and since his return he had been making inquiries as to whether electric instead of steam traction could be advantageously adopted on the Uda Pussellawa railway. Under the conditions that prevail between Nanu-oya and Uda Pussellawa, the water power of the neighbourhood, which was now absolutely wasted, might be utilised in supplying at least part of the tractive power. The Nanu-oya and two tributary streams which join it at the village of Nanu-oya represented a wasted force of about 370 H.P. in ordinary fine weather, which is much increased during the rains. The power of other streams could be utilised, and would go some way towards giving the necessary power for the scheme. The gradients were heavy, and a scheme that dispensed with the haulage of locomotives reduced the tractive power required and lessened the wear and tear of the permanent way. Judging by the gradients that were worked by the electric tramways in Genoa (Sir J. West Ridgeway continued), the road between Nanu-oya and Uda Pussellawa was practicable, but if it was considered desirable to keep away from the cart road between Nanu-oya and Nuwara Eliya, an alternative route could be chosen. A cheaper form of permanent way could be used if the rail and cart traffic were kept separate, and the alternative route would open up the opposite side of the river. This letter was referred to the consulting engineers to the Crown Agents for the Colonies (Messrs. Gregory, Eyles and Waring, of Westminster), and they report that, assuming the volume of water in the Nanu-oya, with its two tributaries, to be equal to a minimum in the driest weather of, say, 300 H.P., it would, in their opinion, afford sufficient power to generate the electric energy required to work the line without the aid of steam engines, on the supposition that there would never be more than two or at the outside three trains in motion at one time, and that all these trains were not at the same moment ascending the steepest gradients. After referring to the initial expenditure in connection with such a project, Messrs. Gregory, Eyles and Waring state that the sharp curves and steep gradients of the line would not form any obstacle to its being worked by electric power, and if, as they believed, an overhead conductor would be the best method of transmitting electric current from the generating station or stations to the motors on the trains, the numerous level crossings of the road which occur on the present route would not be affected by the substitution of electric working for steam. The report concludes as follows:—"Electric traction does not, however, lend itself to lines where the traffic is such that it could be readily dealt with by two or three trains each way per day, and the result of our investigations lead us to the conclusion that the traffic would have to be increased at least three-fold beyond the present estimate before the cost of electric traction could be reduced to that of ordinary steam locomotives. This fact in itself appears to us to point conclusively to the undesirability of adopting electricity as a motive power on the Uda Pussellawa line."

Exeter.—At present the equivalent of 20,000 8 c.p. lamps is connected to the mains, and the demand for current is being maintained in a satisfactory manner.

Folkestone.—The Council are advised by their General Purposes committee to adopt an electric tramway scheme, estimated to cost about £94,000.

Glasgow.—Messrs. Alexander Thomson & Son have been relieved of their contract for bricklaying and other work at the Pinkston power station, and the town clerk and the general manager were entrusted with the task of completing it.

Hampton.—A report has been prepared by Messrs. Handcock and Dykes, in conjunction with the surveyor (Mr. J. Kemp), in which the Council are advised to retain electric lighting powers in their own hands. The estimated cost of electricity works is put at £15,450, and of a refuse destructor at £3,425.

Hanley.—An inquiry was held here on Friday into the application of the Corporation to borrow £9,500 for refuse destructor works and £4,000 for electric lighting, the latter sum to provide two additional Lancashire boilers (£1,400), fuel economisers (£600), feed-water heater (£200), two exhaust smoke flue fans (£276), extensions of boiler-house (£800), the construction of coal bunkers, approach road and coal chutes (£585), and tiling engine room floor and contingencies (£138). The town clerk (Mr. A. Challinor) explained that owing to the increase in the price of materials, the original estimates had been exceeded. The first estimate totalled £4,000, and the amended estimates £5,000. At the meeting of the Council held on Sept. 18 application was ordered to be made for permission to borrow £7,000 for extensions of mains, transformers, meters, &c. This application would be made as soon as the detailed estimates and plans could be completed. In the meantime he applied for so much as was now required in consequence of the increased cost of materials and further requirements at the electricity works amounting to £1,000. The inspector said the resolution of February this year stated that the money was required for a chimney stack and three new boilers, whereas the specific terms of the present application were somewhat different. It was now asked for money to build two new boilers only, and the chimney stack had been dropped. The borough engineer (Mr. J. Lobley) said they were postponing the erection of the third boiler. The inspector said it was merely a technical point, but he could not hold an inquiry into an application when the specific purpose differed from the terms of the resolution passed by the Council. Mr. Lobley said application would be made to the Board later for sanction to borrow for the boiler and chimney stack. The resolution was passed before the plans and estimates were made. The present application, of course, was only for a part of the work contemplated by the Council. An objector (Dr. Adler) said he did not actually oppose, but he wished that certain conditions should be attached to the consent of the Board. The inspector said he thought the Council had better pass a fresh resolution rescinding that under which the present application was made, and then apply for £5,000 instead of £4,000. Mr. Lobley said the cost of street lighting for the year ended Dec. 31 was £1,447. There were 65 arc lamps and 80 columns fitted with incandescent lamps. The amended estimates now submitted made a total of £5,000 instead of £4,000. The extra £1,000 was for the increased cost of boilers, and also for additions not included in the first estimates. The resolution passed at the Council on Aug. 28 ordered an application to borrow £7,000 required for extension of mains, provision of transformers, &c. The additional £1,000 would be included in that £7,000. Ald. Hammersley gave figures showing the increased demand for electric current in the borough. He said demands were made upon them which they could hardly meet. Dr. Folker urged that the electricity works had been mismanaged, and a loss incurred of £2,690. No further loan should be granted until an expert had reported upon the whole question. Ald. Hammersley said that instead of a loss, they had paid off over £5,000, and the sinking fund could not be regarded as a loss. In five years they had made £3,000. There had certainly been no mismanagement. Dr. Adler said there was a feeling in the borough that the works were not being carried on with due skill, and he would grudge no money whatever for electric lighting, because he believed with

Digitized by Google

Ald. Hammersley that there was a great future for the department. But he asked that until an expert had reported to the Council on the question sanction for the loan should be withheld. The inspector said that £4,000 as set forth in this estimate contained a good deal that was urgently required, and to call in an expert would take a considerable time. If they had to wait for that they probably would not get the necessary work done. From what he had heard and seen he thought the officers of the electricity department would themselves be more than pleased to have an expert called in. He questioned whether he had the power to order an expert to be called in. He would, however, report the objection and the suggestions to the Local Government Board.

Holyhead.—The desirability of establishing electricity works is under consideration by the Council. It is considered that water-power available in the vicinity could be utilized in the generation of current, and Mr. Thunderbolt has been requested to consider and report upon the matter.

La Plata (Buenos Ayres).—The City Council has entered into a contract with Mr. Frank R. Cassels for the erection of new electricity supply works. Mr. Cassels also proposes to construct an electric tramway to the Matadero.

Light Railways.—The Long Melford and Hadleigh Light Railway order has been submitted to the Board of Trade for confirmation. Objections by Oct. 24.

The Light Railway Commissioners will hold an inquiry on 17th inst. at Kidderminster into the application of the Kidderminster and District Electric Lighting and Traction Co. for an order to authorise the construction of the Kidderminster and Bewdley light (electric) railway.

An inquiry was held at Rhyl last week into the application of the Rhyl and Prestatyn Light Railway Co. for an order to construct an extension of the Rhyl and Prestatyn light (electric) railway authorised in April last. The company has entered into an agreement to take current from the Council's electricity works. There was no opposition, and the order was granted.

An enquiry was held at Blackburn, on Tuesday, into the application of the Auxiliary and Light Railways and Tramways Co. (Ltd.), for an order to construct the Blackburn, Whalley and Padiham district light railways. On behalf of the promoters, Mr. Balfour Browne, Q.C., said the lines were to connect Blackburn and Burnley, between which towns there were important centres of population. Beginning at Blackburn, they would run north to Rishton, thence to Clayton-le-Moors, to Harwood Bar, over Cock Bridge to Whalley, and from Whalley east to Padiham and Read. The County Council contended that certain portions of the road were too narrow, on which the promoters joined issue. Mr. C. Gradwell, engineer to the promoters, said double lines would be laid throughout. The total length would be 14 miles, and the estimated cost £154,000. For the County Council the clerk (Mr. Clare) said the real question was, who was to pay for the expenditure which must be incurred to remove inconvenience and dangers to the public which would exist if the roads and bridges were allowed to remain as at present. The principle underlying the question was that under no condition whatever should a county ratepayer be asked to subsidise a trading undertaking. If the local districts, who were so anxious for the railways, were desirous of contributing it was all right.

An inquiry was held at Wigan on Wednesday into the application of the Wigan Tramway Co. to construct light (electric) railways of a total length of about 4 miles.

Liverpool.—The Wavertree electric tramway route has been officially inspected on behalf the Board of Trade, and will be opened for traffic within a few days.

Maidstone.—Acting on the advice of their consulting engineer (Mr. S. Sellon), the Council will promote a bill for powers to construct electric tramways in this district.

Metz (Germany).—The tramways are to be converted to electric traction, and the contract has been obtained by the Union Elektricitäts Gesellschaft of Berlin.

Municipal Telephony.—In the Brighton municipal telephone licence the minimum rate for an unlimited service has been fixed at £4. 10s. per annum, for limited service £1. 10s. per annum, and toll of ¼d. per call. The charges for telephone service (limited or unlimited) applies only to subscribers not more than one mile from the nearest switch room, any excess distance to be charged a sum not exceeding £1. 5s. per quarter mile or fraction thereof per annum. The charges for the use of public call offices are to be within the following limits: Maximum 2d., minimum ½d. per message. The consulting telephone engineer (Mr. A. R. Bennett) has been requested to furnish a specification of the pipe or conduit required for the underground telephone wires and of the method of laying, with an estimate of the cost per mile.

Norton (Yorks).—The application of the Northern Counties Electricity Supply Co. for a provisional order is not to be opposed.

Nuneaton.—The Local Government Board have intimated that in regard to the Council's scheme for the extension and development of the electricity works the Board would raise no objection to the Council proceeding with the erection of the chimney shaft and ordering additional machinery. When the Board have been furnished with a copy of the resolution of the Council applying for sanction to borrow a further £2,000 sanction for the total amount required will be given.

Obituary.—The death is announced of Mr. Samuel Maquay, which took place this week at Chertsey. Mr. Maquay was an expert in primary batteries (the "Maquay" battery was on the market some years ago) and was the inventor of a miner's safety lamp.

Pontypridd.—The Council are recommended by their Electric Lighting committee to apply for a provisional order.

Provisional Orders.—The Alnwick, Anfield Plain, Benfieldside (Durham) and the Kirkheaton (Yorks.) and Bellingham (Northumberland) District Councils have consented to the applications of the Northern Counties Electricity Supply Co. of Newcastle-on-Tyne for provisional electric lighting orders.

Provisional Order Transfer.—The Harrow Council notify their intention to transfer their 1900 electric lighting order to the Harrow Electric Light and Power Co. (Ltd.). The company is to pay the cost of obtaining the order, and the right to purchase the undertaking on certain contingencies is reserved to the Council.

Ripon.—The question of establishing electricity works is under consideration, and last week a deputation visited the Harrogate electricity works. The borough electrical engineer (Mr. George Wilkinson) personally conducted the deputation and supplied technical details.

Russia.—Some time ago Messrs. Siemens and Halske secured a contract for lighting the town of Nicolaiev by electricity, overhead conductors being proposed. Owing to the delay in granting approval of the overhead system by the Department of Telegraphs the work of construction and equipment has been hampered, and little progress with the work has, we understand, been made.

Southampton.—Mr. A. P. Trotter inspected the Portswood-Docks Station section of the Corporation electric tramways on Saturday last, and the lines have been opened for traffic.

Strabane (Ireland).—An electrical engineer is to be called in to report upon the advisability of establishing electricity works.

Tonbridge (Kent).—At an inquest on the bodies of four persons burnt to death at a fire which occurred in this town recently, the coroner's jury in returning a verdict of accidental death strongly recommended the use of electric fire calls, and the evidence adduced certainly bears out the urgency of the recommendation.

Tramway Extensions in Middlesex and Surrey.—As we have already announced, the London United Tramways (Ltd.) have given notice to local authorities in Middlesex and Surrey of intention to apply next session for powers to construct additional extensions of their system of electric tramways. The extensions will include 23 miles of tramway in Surrey, 20 miles in Middlesex, and 20 miles in the County of London. Under the proposed bill the existing system is to be extended to St. Pancras, Marylebone, and Fulham, and across the Thames to Putney, northward to Willesden and Southall, and westward to Sunbury. The Surrey extensions include a length of over 4 miles, connecting Putney with Richmond. Another line will leave the southern approach to Hammersmith Bridge, and pass across Barnes Common; and there is also to be an extension from Kew Bridge to Richmond. In Middlesex lines will connect Isleworth with St. Margaret's, Hounslow and Cranford, Brentford with Ealing, and Twickenham with Hanworth and Kempton Park. Intercommunication lines are also scheduled between different parts of Kingston, Putney Hill, Surbiton, Tolworth, Hook, Long Ditton, Thames Ditton, Esher, and Hampton Court.

Tramway Strike.—The motor men and conductors of the Oldham, Ashton and Hyde electric tramway came out on strike on Saturday night, in consequence, it is alleged, of the manager's discharging union employés and replacing them by non-unionists.

Tynemouth.—Application has been made for sanction to a loan of £10,000 for refuse destructor works.

Wellington (Salop).—A provisional order is to be applied for by the Council.

Wisbech.—A unanimous resolution in favour of applying for a provisional order has been passed by the Council.

Workmen's Compensation.—At Loughborough County Court, John Knight, a mechanic employed at the Brush Company's works, applied for a declaration of liability, which the respondents admitted he was entitled to. Plaintiff's eyesight had been injured, and the company had paid him since the accident about the same wages that he was earning at the time of the occurrence. The Court was asked to make a declaration of liability on the ground that he was suffering from permanent physical injury. The company had made inquiries, and they found that the work done by plaintiff since the accident

Digitized by Google

had been perfectly satisfactory. If it turned out that he was not able to do his work so well he might have to take less money. Judge Wightman Wood, in granting the order, said plaintiff had got all he was entitled to. At the present time he was losing nothing through the accident. If he got less he had a right to come to the Court and get the amount put in.

At the St. Helens County Court on Wednesday Judge Collier was asked to arbitrate in a claim for compensation made by George Hindle against the British Insulated Wire Co. in respect of an accident which happened on Dec 29, 1899, at the St. Helens electric tramway depot, when Hindle fell down a pit and fractured his thigh and arm. He was incapacitated for 40 weeks, and claimed 19s. 6d. per week, half his average earnings. His Honour decided that the accident did not come within the Compensation Act, because it happened in a building of which the respondents were not the occupiers. They were therefore not undertakers within the meaning of the Act.

Electro-Harmonic Society.—This society has returned to its old haunts at the St. James's Hall Restaurant, and the first (smoking) concert of the season will be given on Oct. 12 at 8 p.m. Members are desired to use their influence in introducing new members to the society. A committee meeting is to be held prior to the first concert, and the names of new candidates will be received by Mr. C. E. Grove, hon. sec., Rosedale, Selsdon-road, Wanstead, up to and including Friday, Oct. 5, in time for the issue of tickets for the first concert to all new members elected on that date. The present membership totals about 300.

EDUCATIONAL NOTICES.

Birmingham University Calendar.—We have received a copy of the first calendar of the University of Birmingham. Full particulars of the course of instruction in the faculty of science, including electrical, civil, and mechanical engineering, metallurgy, chemistry, &c., are given.

King's College (London).—The evening classes in electrical engineering commence on Oct. 8.

Morley Memorial College.—The 1900-1901 session of this College for working men and women, Waterloo-road, London, S.E., begins on Oct. 1. Some particulars of the classes, fees, &c., are given in an advertisement. Miss Emma Cons is hon. sec.

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers, or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London:—

"The Art of Electrolytic Separation of Metals."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free. The author treats fully both the theoretical principles of the art of electrolytic separation of metals and the practical rules and details of technical application on a commercial scale. The work is adapted to the use of the manufacturer as well as the student.

"Electromagnetic Theory."—By Oliver Heaviside. *Vol. I.*, 12s. 6d. *Vol. II.*, 12s. 6d.

"Electrical Testing for Telegraph Engineers."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. Demy 8vo, fully illustrated. 10s. 6d., post free.

"Electrical Engineering Formulæ," a pocket book, by Messrs. W. Geipel and H. M. Kilgour; price 7s. 6d.; by post, 7s. 9d.; abroad, 8s. *New Edition nearly ready.*

"Bibliography of X-Ray Literature and Research."—A valuable compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of general as well as special information bearing upon the whole subject of electrical discharge research. Edited by C. E. S. Phillips. Price 5s., post free.

"The Manufacture of Electric Light Carbons."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated, price 1s. 6d.; post free, 1s. 9d. In this work the author gives useful hints as to the manufacture of electric light carbons, including the preparation of material, firing, saturating, and coring, together with a description and estimate of cost of the plant required.

"Localisation of Faults in Electric Light Mains."—By F. C. Raphael. Price 5s., post free. The book deals with the important subject of localising faults in electric light and power cables; and the various methods of insulation testing are here collected and discussed.

"Wireless Telegraphy: Signalling across Space without Wires by Electric Waves." A Review of the Work of Hertz and his Successors.—By Dr. O. J. Lodge, with a large number of illustrations, bringing this latest application of electrical science quite up to date. New and Enlarged Edition, 5s. nett. *Now ready.*

"The Centenary of the Electric Current, 1799-1899."—By Dr. J. A. Fleming. Price, paper covers, 1s. net, post free 1s. 3d.; strong cloth, 2s. 6d., post free.

"The Manufacture of Carbons for all Electrical Purposes."—by Francis Jehl. 10s. 6d., post free. This is a practical handbook, giving a complete description of the art of making carbons for electric lighting, electrodes, &c., with particulars of the various gas generators and furnaces used in carbonising. The work also contains particulars of the cost, &c. of erecting and working carbon works, and plans of a model factory.

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office no later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

TENDERS INVITED.

Bermondsey (London) Vestry invite tenders for steam, feed exhaust, and drain pipes, feed pumps, water storage tank and sundry ironwork, and also for steam dynamos, battery charging motor, booster, and balancer. Specifications may be inspected, but not obtained, at the offices of the consulting engineers (Messrs. Kincaid, Waller and Manville), 29, Great George-street, London, S.W. An advertisement gives further particulars, and tenders must be forwarded to the Vestry clerk (Mr. Frederick Ryall), by Oct. 15.

Swansea Corporation invite tenders for cast-iron arc and incandescent lamp standards. Specifications may be obtained at the Guildhall, Swansea, and may be inspected (but not obtained) at the offices of the consulting engineers (Messrs. Kincaid, Waller and Manville), 29, Great George-street, Westminster, S.W. An advertisement gives further particulars, and tenders must be forwarded to Messrs. Kincaid, Waller and Manville before noon Oct. 10.

Sunderland Corporation invite tenders for the supply of 24 car bodies, trucks, and electrical equipment. An advertisement contains further particulars, and specifications may be obtained on application to the borough electrical engineer (Mr. J. F. C. Snell), Dunning-street. Tenders, addressed Chairman of Tramways Committee, Town Hall, Sunderland, must be sent to the town clerk (Mr. Fras. M. Bowey) by noon Oct. 15.

Warrington Corporation invite tenders for wiring the electricity station and central sanitary depôt at Howley. Specifications may be obtained from Mr. W. H. Grimsdale, Bank House, Warrington. See advertisement.

The *Secretary of State for India* invites tenders for (1) a complete electrical installation for supplying to a factory from a waterfall 3 miles distant, and (2) a complete hydraulic installation to develop about 500 H P. Further particulars are given in an advertisement, and tenders must be delivered at the India Office, Whitehall, S.W., by 2 p.m. Oct. 16.

Bootle Corporation invite tenders for a steam dynamo. An advertisement gives further particulars, and tenders, addressed Chairman of Electric Traction and Lighting committee, must be delivered at the Town Hall, Bootle, before Oct. 13.

Maidstone Corporation invite tenders for surface condenser and feed pumps. Specification, &c., may be obtained after Oct. 2 from the consulting engineers (Messrs. Stevens and Barker), St. Peter's-street, Maidstone, and tenders should be sent to the town clerk (Mr. Herbert Monckton) before 10 a.m. Oct. 16.

The directors of the *Lancashire and Yorkshire Railway* invite tenders for supply of stores during the 12 months ending Oct. 31, 1901. Among the articles required are brake blocks, copper, india-rubber, iron castings, ironmongery, sundry tools, &c. Tenders to the secretary (Mr. R. C. Irwin), Hunt's Bank, Manchester, by 10 a.m. Oct. 8.

Ilford District Council invite tenders for direct-current meters and cutouts. Tenders to clerk by noon Oct. 8.

Grimsby Corporation require tenders for wiring the Free Library. Tenders to borough electrical engineer by Oct. 6.

Manchester Tramways committee invite tenders for cast-iron bases for tramway poles. Tenders to chairman of committee by Oct. 1.

Hoylake and West Kirby District Council invite tenders for "free wiring" of premises in district. Tenders to clerk, Council Offices, Hoylake, by Oct. 4.

Birkenhead Corporation invite tenders for feeder mains, &c. Tenders to town clerk (Mr. Alfred Gill) by 4 p.m. Oct. 2.

Nottingham Council invite tenders for 1,500 tons of steel girder tram rails and 76 tons of fishplates. Tenders to town clerk before Oct. 8.

Aberdeen Town Council invite offers for 25 electrical tramcars, and for equipments for six horse cars about to be converted. Tenders before noon of Oct. 17.

Bradford Corporation require tenders for an engine and dynamo, switchboard apparatus, &c., for their destructor works. Tenders to town clerk before Oct. 9.

Eray (Ireland) District Council will on Oct. 4 receive and consider tenders for electric light supplies for 12 months, including cables, house wires, switches, holders, incandescent lamps, &c. Tenders to clerk to Council, before 10 a.m. Oct. 4.

Sheffield Corporation invite tenders for: (*a*) Two 600kw. two-phase steam alternators and exciters, and (*b*) alteration of present single-

Digitized by Google

phase plant to two-phase. Tenders to chief engineer and manager of electric supply department (Mr. S. E. Fedden) by Oct. 6.

Dublin Corporation invite tenders for power machinery at Ringsend, including pumping engines and pumps, boilers, electric motors and pumps. Tenders to town clerk by noon Oct. 3.

Dublin Electric Lighting committee invite tenders for electricity mains and accessories. Tenders to town clerk by 4 p.m. Oct. 4.

Eastbourne Corporation invite tenders for water-tube boilers, with fittings, feed pumps, &c.; 400kw. steam alternator, with exciter (vertical enclosed high-speed engine); and main switchboard and connections. Tenders to town clerk by noon Oct. 4.

Tenders are invited for the erection of machine shops, &c, at *Thornbury*, Bradford, for Rosling, Appleby, and Fynn. Tenders to S. Jackson & Son, Tanfield Chambers, Bradford, by Oct. 6.

Hackney (London) Electric Lighting committee invite tenders for electricity supply mains. Tenders to vestry clerk by 5 p.m. Oct. 3.

Tenders are invited for wiring the *Suffolk* County Asylum, Melton. Tenders to Mr. A. T. Cobbold, County Hall, Ipswich, by Oct. 5.

Belgian State Railway authorities invite tenders until Oct. 10 for 60 tons of galvanised iron wire (4mm. diameter), 15 tons (3mm. diameter), and 65,000 telephone and 20,000 telegraph porcelain insulators.

Pozuelo (Albacete, Spain) Municipal Council require tenders until Oct. 7 for the electric lighting concession for 40 years. Tenders to el Secretario del Azuntamiento.

The municipal Council of *Callosa de Ensarria* (Alicante, Spain), invite tenders until Oct. 12 for the concession for electric lighting for 50 years.

Vélez Blanco (Almeria, Spain) municipality also invite tenders until Oct. 15 for the concession for electric lighting.

Tenders are invited for the electric lighting of *Palma* (Spain) for 20 years. Tenders to Municipal Council by Oct. 30.

TENDERS RECEIVED AND ACCEPTED.

Croydon Town Council have accepted the following tenders for electric tramway work:—

British Thomson-Houston Co., car bodies, motor car equipment, feeders, overhead construction, excavating work, &c.
Leeds Steel Works, rails.
Hilton, Anderson, Brooks & Co., cement.
Bart, Boulton and Haywood (Ltd.), soft wood paving blocks.
Millar's Jarrah Forests Co., hard wood blocks.

Shipley (Yorks.) District Council have accepted the following tenders:—

John Spencer (Ltd.), steam and exhaust pipes.
Eclipse Brass and Copper Co., storage battery.
Mavor and Coulson, switchboard and connections.
Western Electric Co., cables.

Greenock Police Board have accepted the tender of Messrs. Babcock and Wilcox for the supply of water-tube boilers, and that of the Silvertown Co. for two steam dynamos (high-speed enclosed engines), boosters, switchboard, steam and exhaust pipes, &c., for their electric tramway scheme.

The contract for the storage battery required for the Witney electricity supply station has been secured by the Hart Accumulator Co.

Walsall Town Council have accepted the tender of the Electrical Power Storage Co. for extensions to their storage battery at £679. 10s.

APPOINTMENTS VACANT AND FILLED.

Barnes District Council require a clerk of works for their electricity undertaking to superintend the laying of cables and the erection of the generating plant under the consulting engineer (Mr. W. Fairley). An advertisement gives further particulars, and applications must be sent to the clerk (Mr. J. E. Anderson), Council Offices, High-street, Mortlake, S.W., by 4 p.m. Oct. 4.

The Council of Hartley College (Southampton) invite applications for the appointment of assistant lecturer in engineering. Applications to clerk (Mr. D. Kiddle) by Oct. 3. See advertisement.

Islington (London) Vestry require a draughtsman and an engine driver for their electricity department. Applications to the vestry clerk (Mr. W. F. Dewey), Vestry Hall, Upper-street, London, N., by Oct. 8. See advertisements.

An electrician is required for the County Asylum, Prestwich, near Manchester. Applications to the superintendent. See advertisement.

Manchester Tramways committee require a lady superintendent for the ticket and cash-counting department. Applications by 6th prox. See advertisement.

Bermondsey (London) Vestry require a resident electrical engineer. Applications to clerk (Mr. Frederick Ryall), Town Hall, Bermondsey, London, S.E., by noon Oct. 3.

An arc lamp trimmer, a mechanical draughtsman and a clerk are required for the Whitechapel electricity department. Applications to engineer (Mr. W. C. P. Tapper), 27, Osborn-street, London, E.

A master for experimental science and mathematics is required for Peebles County High School. Applications to clerk before 1st prox.

We are informed by the India Office that Mr. W. D. Macgregor, of Edinburgh, has been appointed an assistant superintendent in the Indian Government Telegraph Department. The appointment was advertised in *The Electrician* in May last.

Mr. R. M. Archer, A.R.C.S., has been appointed lecturer and demonstrator in physics and electrical engineering, and Mr. S. Sinkinson, B.Sc., lecturer and demonstrator in mechanical engineering, at the Derby Municipal Technical College.

Mr. A. P. Laurie, M.A., lecturer in physics and chemistry at St. Mary's Hospital, London, has been elected out of a short list of five to the principalship of the Heriot Watt College, Edinburgh, in succession to Prof. F. Grant Ogilvie, who was recently appointed director of the Museum of Science and Art.

Mr. R. S. Willows, D.Sc., B.A., has been appointed assistant lecturer in physics and electrical engineering at Battersea Polytechnic.

Mr. Wm. Irving, works manager of Messrs. James Carmichael & Co., has been appointed mechanical engineer in charge of the Pinkston power station, Port Dundas, Glasgow.

Mr. F. Dawe, Swansea, has been appointed general foreman of the Croydon Tramways.

In our last issue we referred to the appointment of a meter superintendent at Sheffield, and by a clerical error the name was given as Mr. A. J. Oridge instead of Mr. A. J. Cridge.

BUSINESS NOTICES.

Warning.—Messrs. J. A. and K. J. McMullen, consulting electrical engineers, of 17, Gracechurch-street, London, E.C., and Hornchurch, Essex, desire attention to be called to an advertisement appearing in another column warning manufacturers and dealers against supplying goods in their name to a person of the name of Harvey, trading, or pretending to trade, at Ware, Herts., under the style of "The Hertfordshire Engineering Co, Ltd." We are informed and believe that Messrs. McMullen have written authority from the man Harvey to issue this caution, and persons interested may see all the documents at the offices of Messrs. Carter and Bell, solicitors, 6, Idol-lane, Eastcheap, London, E.C.

Mr. T. Vaughan Hughes, Norwich Union Chambers, Edmund-street, Birmingham, has entered into partnership with Dr. E. A. Warrington in connection with metallurgical and analytical work, but continues his consulting electrical engineering practice at the above address.

The National Telephone Co. (Ltd.) announce that the head offices of the company have been removed to the new "Telephone House," Victoria-embankment, London, E.C.

BANKRUPTCIES, LIQUIDATIONS, &c.

George Stegmann, electrical engineer, 45, St. John's-hill, Clapham Junction, London, S.W., has executed a deed of arrangement. Liabilities £2,440. 5s. 8d., assets £5,600. There are secured creditors to the extent of £2,241. 3s. 8d. Mr. F. W. Davis, 95 and 97, Finsbury-pavement, E.C. is trustee. The principal creditors include:—

General Electric Co.	£662	J. H. Holmes & Co.	£74
Veritye Ltd.	386	Addington Timber Co.	43
W. Rickard	229	Chloride Elec. Storage Synd.	23
S. Evans & Co.	141	Atlas Carbon Co.	20
Hart Accumulator Co.	141	Reliance Rubber Co.	19
Electrical Co.	140	Reliance Wire Co.	18
Gabriel & Angenault	128	I Frankenburg	17
Markt Bros.	126	Russell & Co.	14
Julius Sax & Co.	108	Nettlefolds	14
Elec. Power Storage Co.	106	Croggon & Co.	13
Johnstone, Benjamin & Co.	90	Simplex Steel Conduit Co.	13

A meeting of the Electrical Pioneer Syndicate (Ltd.) will be held at 39, Waterloo-street, Birmingham, on Oct. 25, to receive an account of the winding-up.

In the bankruptcy of R. Foster and W. Baker, trading as Robert Foster & Co., and the Nelson Electrical Engineering Co, at Nelson and Burnley, the first meeting of creditors will take place on 28th inst. at the Exchange Hotel, Nicholas-street, Burnley, and the public examination on the same date at the Court-house, Burnley.

Winding-Up Petition.—A petition for the winding-up of the Acetylene Light Syndicate (Ltd.) has been presented by the Brush Company, and will be heard at the Guildhall, Bath, on Oct. 18.

Engineering Works for Sale.—Our advertisement columns contain particulars of engineering works in the city of Dublin which are offered for sale by tender as a going concern owing to the death

Digitized by Google

of the late proprietor. The works are centrally situated and have a suitable set of offices, pattern shop, machine shop and foundry, and smith's shop, together with a number of tools which are all of modern type, many of them being new. Tenders are to be addressed to Mr. A. Basil Wilson, M.I.C.E., Maryville, Malone, Belfast, from whom further particulars can be obtained.

Artistic Electric Light Fittings and Accessories.—The Electrical Co., to meet the increased demand for their manufactures, have opened an extensive range of show rooms at 162, Shaftesbury-avenue, London, W.C., for the display of new and artistic designs in electric light fittings and accessories. An immense stock of electroliers, brackets, pendants, &c., are shown in a particularly effective manner. Success in the exhibition of this class of goods is by no means general, but the method adopted by the Electrical Co. in displaying a particular class of designs and styles of fittings in rooms specially arranged for their reception, while it is not entirely novel in idea, is certainly calculated to, and does in fact, afford the best means of effective display. The range of fittings shown in the new rooms embraces those for mansions, small private residences, business offices, &c. Fittings in oxidised silver are well grouped in one of the rooms, while in another ornamental and classical figures and shades for drawing rooms, boudoirs, reception rooms, &c., make an artistic setting. Hammered iron and bronze work form a feature of another department, while an excellent selection of the newest designs in French artistic metal work should prove attractive to that large class of installation contractors engaged in the fitting up of town and country houses. Electric current is available for showing the fittings to the best advantage, and altogether the display is one which architects, contractors, and the trade generally may be advised to visit. Contracts are now being placed for this class of goods for the coming winter season, and the Electrical Co. have certainly laid themselves out for meeting to the full the most exacting requirements.

Cooling Tower Contracts.—The Wheeler Condenser and Engineering Co. have recently received orders for cooling towers from the Newcastle-on-Tyne Electric Supply Co. (2,000 H.P. capacity), Messrs. Platt Bros., Oldham (1,000 H.P.), Bromley (Kent) Electric Light and Power Co. (1,000 H.P.), and Southend Corporation power station (1,000 H.P.). In the two latter cases the contracts include equipment of condensing plants, exhaust oil separators, feed-water heaters, the cooling towers being of the fan-driven type.

4,000 H.P. Steam Set.—The Berlin Electricitätswerke Gesellschaft have added a 4,000 H.P. steam dynamo to their central station on the Upper Spree. The dynamo, which was constructed by the Allgemeine Electricitäts Gesellschaft of Berlin weighs 16 tons.

Westinghouse Plant.—Circular 1,031, issued by the British Westinghouse Co., describes and illustrates belt-driven polyphase alternators, the particular machines dealt with being 180kw. and 375kw. two-phase alternators.

Electric Heating and Cooking.—We have received from the Simplex Electrical Co., of Cambridgeport, Mass., U.S.A., a descriptive catalogue of electric heating and cooking apparatus. The value of the list is increased by a number of excellent illustrations of a large variety of apparatus manufactured by the company under the patents owned by the American Electric Heating Corporation.

Paris Exhibition Awards.—Messrs. Geipel and Lange inform us that the following specialities, for which they are agents, obtained distinction at Paris: Brown-Boveri three-phase plant (grand prix), Ward-Leonard electric controlling apparatus (gold medal), Vulcan meter (gold medal), Chapman voltage regulator (bronze medal), and Geipel trap (hors concours). Eighty of these traps were used for draining the whole of the steam piping system of the exhibition.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Sept. 19 to Sept. 25, with the ports of destination:—

Africa.—Alexandria, £140; Cape Town, £105; Durban, £517 (including £147 telegraph apparatus); Port Elizabeth, £473 (telegraph material). *Argentina*—Buenos Ayres, £937 (including £842 telegraph material). *Australasia*—Adelaide, £61; Auckland, £90; Launceston, £231; Lyttleton, £300; Melbourne, £432; Otago, £134; Sydney, £1,816 (including £120 telegraph material); Wellington, £584 (including £492 telegraph material). *Belgium*—Brussels, £36; Ostend, £274. *Canada*—Halifax, £2,690 (telegraph cable); Toronto, £20. *Chili*, £200; Valparaiso, £80 *Cochin China*, £21. *Denmark*—Copenhagen, £271 (telegraph wire). *Germany*—Hamburg, £700 (telegraph material). *Gibraltar*, £136. *Holland*—Amsterdam, £95; Rotterdam, £17 (telegraph wire). *Hong Kong*, £76. *India*—Bombay, £58; Calcutta, £336 (including £126 telegraph wire). *Japan*—Yokohama, £13,050 (telegraph material). *Mexico*—Vera Cruz, £73 (telegraph material). *Norway*—Bergen, £14,910 (telegraph cable). *Portugal*—Lisbon, £45. *Russia*—St. Petersburg, £70 (telegraph paper). *Straits Settlements*—Singapore, £40. *Sweden*—Stockholm, £233 (telegraph cable). Total £39,291, against £11,232 in the corresponding week last year (Sept. 20 to Sept. 26.)

PATENT RECORD.

The following list of Applications for Patents and Specifications published has been compiled for this journal by MESSRS. J. C. CHAPMAN and Co., *Chartered Patent Agents, of 70, Chancery-lane, W.C., from whom any available information in connection with Patents, Designs, and Trade Marks may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned Applications are not open to public inspection until after the acceptance of the complete Specification. The names within parentheses are those of communicators of inventions. When complete specification accompanies application, an asterisk is affixed.*

August 3, 1900.

13,951. J. WEISS. London. Improvements relating to electric muffles or furnaces.

13,962. C. A. JENSEN. London. Improvements in electric signal registering systems. (The Yargae Signalphone Manufacturing Company, United States.)

13,963. E. F. CASSEL. London. Improvements in and relating to cypher code systems for use in transmission of cable, telegraphic, and other forms of written messages.*

13,966. THE BRITISH THOMSON-HOUSTON CO. (LTD.) London. Improvements in Röntgen-ray tubes. (E. Thomson, United States.)*

13,967. THE BRITISH THOMSON-HOUSTON CO. (LTD.). London. Improvements in systems of electrical distribution. (E. W. Rice, jun., United States.)*

13,968. THE BRITISH THOMSON-HOUSTON CO. (LTD.). London. Improvements in systems of electric motor control. (A. G. Davis, United States.)*

13,969. THE BRITISH THOMSON-HOUSTON CO. (LTD.). London. Improvements in insulated electric conductors. (W. Le Roy Emmet, United States.)*

13,970. THE BRITISH THOMSON-HOUSTON CO. (LTD.). London. Improvements in armatures for dynamo-electric machines. (C. P. Steinmetz, United States.)*

13,971. THE BRITISH THOMSON-HOUSTON CO. (LTD.). London. Improvements in rectifiers for alternating electric currents. (E. Thomson, United States.)*

13,972. THE BRITISH THOMSON-HOUSTON CO. (LTD.). London. Improvements in systems of electrical distribution. (H. D. Lunt, United States.)*

13,973. THE BRITISH THOMSON-HOUSTON CO. (LTD.). London. Improvements in insulated electric conductors. (W. Le Roy Emmet, United States.)*

13,974. THE BRITISH THOMSON-HOUSTON CO. (LTD.). London. Improvements in rail bonds for electric railroads. (J. R. Lovejoy, United States.)*

13,975. THE BRITISH THOMSON-HOUSTON CO. (LTD.). London. Improvements in systems for controlling electric motors. (C. E. Barry, United States.)*

13,999. L. BÉNARD. London. Improvements in arc lamps.

August 4, 1900.

14,037. H. T. DAWSON and H. A. DAWSON. Coventry. Improvements in or relating to electrical transmission gear for motor cars and other machinery.

14,053. C. R. CORMAC. London. A lightning protector for telephones.

14,054. J. SAX & CO. (LTD.) and J. AIRD. London. Improvements in indicators for electric bells and the like.*

14,063. G. C. PILLINGER and A. VANDAM. London. Improvements in and connected with combined switches and fuses.

14,067. W. S. SIMPSON. London. Apparatus for generating and utilizing electric energy.

August 7, 1900.

14,086. A. C. BROWN. London. Improvements in wireless or Hertzian telegraphy.

14,101. W. G. HEYS. Manchester. Improvements in coils or helices for electrical purposes. (J. Scott, R. Varley, and J. C. Anderson, United States.)*

14,104. O. LANCKNER. London. Improvements in electrodes for the use in electro-chemical processes. (A. Vogelsang, Germany.)*

14,134. E. J. PENNINGTON. London. Improvements in or relating to electrical traction.

14,139. W. B. PURVIS. London. Improvements relating to electric railway systems.*

August 8, 1900.

14,170. H. H. HILL. Middlesex. A quick make-and-break switch for electrical purposes.

14,212. A. J. BOULT. London. Improvements in or relating to electric furnaces. (The Union Carbide Co., United States.)*

14,215. J. KÖRNER, P. KÖRNER and E. MAHLA. London. Means of fixing electrical appliances to ceilings, walls, furniture and the like.

14,237. C. ZIMMERMANN. London. A safety device or fender for electric tramways or the like.

August 9, 1900.

14,248. A. ECKSTEIN and A. E. MITCHELL. Manchester. An improved electrical replacement indicator.

14,275. G. C. DYMOND. Liverpool. Improvements in and relating to electro-chemical or copying telegraphs. (The Kopier-Telegraph Gesellschaft mit beschränkter Haftung, Germany.)*

14,281. G. FERRIÉ. London. Improvements in telegraphy by means of alternating currents and imperfect contacts. (Date applied for under Patents, &c., Act, 1883, sec. 103, 1900, being date of application.)

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1899.

12,566. ABEL (Karmin). Arrangement and connections of the windings of dynamo machines.
14,572. ROSENFELD, ZELENAY, and DULAIT. System of electro-dynamic propulsion.
14,703. BREMER. Carbon electrodes for arc lamps.
14,806. MAGINI. Counter or meter for electric lamps, motors, and other electric apparatus.
14,878. COLLEY. Covering electrical and other wires and apparatus therefor.
15,017. WEYMERSCH. Electric accumulators or secondary batteries.
15,207. NEUMANN. Production of battery plates or other articles by electrolytic or chemical depositions of spongy metal.
15,268. BRITISH THOMSON-HOUSTON CO. (LTD.) (Rice). Electric lamps.
15,418. EDMUNDS. Insulated electrical conductors or cables.
15,816. WILDE. Electromagnetic rail brakes.
15,882. LUCAS. Apparatus for operating two or more electrical regulating switches or resistance devices together or separately.
15,911. JONES. Electro-magnetic apparatus.
16,055. JONES. Electric switches.
16,083. CUÉNOD. Controlling devices for electric currents.
16,091. RICHARDSON and RAMSBOTTOM. Electrical apparatus suitable for lighting, cauterising and other purposes.
15,199. OPPENHEIMER (Actiengesellschaft Mix and Genest). Switches for high voltage.
16,267. LOCK and MILNER. Electrical apparatus for sorting articles according to one of their dimensions.
16,293. DAVIES. Manufacture of leaden plates for secondary batteries or accumulators, and in moulds and tools to be employed in such manufacture.
16,382. LORRAIN (Sawyer and Robb). Spindles and the driving of the same by electricity.
16,395. WAHLSTRÖM. Arrangement for controlling electric elevators.
16,824. GRAUER. Apparatus for electro-chemical and electro-thermic melting operations, especially for the production of calcium carbide.
17,229. BROOKS and HOLT. Polishing or finishing of electro-plated and other articles.
17,257. ADAMS. Apparatus for generating electrical pressure.
17,815. ATKINSON. Direct-acting electric generators and directly-driven electric compressors for air or other gases.
17,877. BESTWICK. Composition of or from which may be manufactured tubes for various purposes, tyres, and other articles requiring more or less flexibility, or for use as a non-conductor of electricity.
17,878. BESTWICK. Composition of or from which may be manufactured billiard-balls, handles for umbrellas or sticks, electric buttons, and other articles of a like nature and general utility, and as a substitute for mica.
17,953. RATHBONE. Means and appliances connected with air-tight electric arc lamps.
19,020. WILBY. Electric arc lamps.

1900.

516. VESELY. Points and switches of electric tramways and railways.
1,680. SAYER. Picking up electric current sent from a generating station by a railway car and returning it.
2,702. RIETER. Electromagnetic brake dynamometer.
5,257. HEYS (Scott, Varley and Anderson). Apparatus for winding or producing coils, bobbins, helices, or the like for electrical and other purposes.
5,727. TRUDEAU. Electric heating and apparatus therefor.
6,703. BERGMANN. Magneto-electric machines for igniting purposes.
7,314. SAYER. Boiling and vapourising fluids by electricity.
7,781. ROBINSON. Apparatus for wireless telegraphy. (Secret document under sec. 44 of the Patents, &c., Act, 1883.)
7,782. ROBINSON. Transmitting and receiving switch for wireless telegraphy. (Secret document under sec. 44 of the Patents, &c., 1883.)
8,344. MINN and SUN ELECTRICAL CO. (LTD.). Double pin plug and socket for electrical connections.
8,671. SCHULZ. Construction of electric switch.
8,704. CARTER. Apparatus for facilitating the photometry of arc lamps and the like sources of light.

COMPANIES' MEETINGS AND REPORTS.

Willans and Robinson (Ltd.).

The thirteenth half-yearly report of the directors of this company (for the half-year to June 30) states that after writing off as depreciation £5,630. 19s. 4d., and paying interest on debenture stock, the balance to credit of profit and loss at the end of the half-year (including £5,212. 1s. 1d. brought forward) was £31,399. 8s. 11d. Out of this the directors propose dividends at the rate of 6 per cent. per annum on the preference and 10 per cent. per annum upon the ordinary shares (taking £14,923. 17s. 10d.). The amount payable to the original directors being £4,218. 8s. 2d., the balance available is £12,257. 2s. 11d. £2,000 of this is carried to debenture redemption, and £3,500 to reserve, leaving £6,757. 2s. 11d. to be carried forward. The balance of capital remaining unissued (10,000 preference and 10,000 ordinary shares) was allotted to the shareholders in June last, and 8,788 preference and 9,425 ordinary shares were taken up, and the balance was so greatly over-applied for by the shareholders that it could only be allotted in about the proportion of one preference share for every 10, and one ordinary share for every 50 applied for.

Of the balance of £29,656. 2s. on share premiums account, £5,000 has been applied to writing down the company's property at Thames Ditton and £20,000 has been transferred to reserve. The balance (£4,656. 2s.) has been brought up to £21,493. 2s. by payments under the first instalment of the premiums upon the 1900 issue of shares.

The large engine, capable of working up to 3,000 I.H.P., exhibited by the company at Paris, in conjunction with a dynamo by Messrs. Siemens Bros. & Co., has been awarded a Grand Prix, another similar award being made for the dynamo.

Owing partly to difficulty in obtaining dynamos from the makers, and partly to other causes for which the company is not responsible, an unusually large value of completed or nearly completed engines (all on order) remained in the accounts at the end of the half-year under the head of "unfinished work." Had it been possible to deliver and invoice these engines in the half-year, a larger amount of profit would have been brought into the accounts.

DIRECT WEST INDIA CABLE CO. (LTD.)—The third annual general meeting was held at the offices yesterday (Thursday), under the presidency of Mr. Thomas Skinner. The chairman proposed the adoption of the report and accounts to June 30, in which the directors stated that the net result was a profit of £5,455. 18s. 3d., which was satisfactory considering the circumstances under which the company had to work, but compared unfavourably with a profit of £19,186. 1s. 1d. made in the previous year, when revenue was greatly aided by the Spanish-American war and other unusual occurrences. An interim dividend of 2½ per cent. had already been paid, and it was now proposed to make a further distribution of 3½ per cent. which would leave £3,655. 18s. 3d. to be carried forward, increasing the amount to credit of revenue to £25,146. 15s. 1d. The revenue account for the year ended June 30 showed that the revenue from messages, subsidies, and other receipts had been £19,186. 4s., from interest on investments £1,891. 13s. 7d., and from transfer fees £6. 2s. 6d. The company's cables continued to work with complete efficiency. Under the deed the redemption of the company's debentures commenced in June last, and £9,000 of debentures had been acquired and cancelled. The retiring directors, Mr. Geo. G. Ward and Mr. Fred. Ward offered themselves for re-election. The report was unanimously adopted.

HALIFAX AND BERMUDAS CABLE CO. (LTD.)—The eleventh annual general meeting of this company was held at the offices yesterday (Thursday), Mr. Thomas Skinner presiding. The directors' report for the year ended June 30 last stated that the net result of the year's working was a profit of £3,795. 7s. 9d., compared with £10,141. 19s. 10d. for the previous year. This important reduction was mainly due to normal times as compared with a period which was benefited largely by traffic arising from the Spanish-American war. An interim dividend of 2½ per cent. had already been paid, and it was now proposed to make a further equal payment, which would together absorb £2,500, and leave £1,295. 7s. 9d. to be carried forward. This would increase the amount to credit of revenue to £13,092. 8s. 3d. The revenue account for the year ended June 30, 1900, showed that £16,379. 17s. was derived in that period from messages, subsidies, and other receipts, £1,007. 17s. 9d. from interest on investments and deposits, and £3 from transfer fees. The company's cable continued to work with complete efficiency. Offers for the sale of debentures to the trustees were invited in December and June last, and £5,197. 2s. 5d. was paid for £5,200 of debentures. The retiring directors, Mr. Geo. G. Ward and Mr. Fred. Ward, offered themselves for re-election. The chairman proposed and Mr. T. G. H. Glynn seconded the adoption of the report and accounts, which were unanimously passed.

MERSEY RAILWAY CO.—At the half-yearly meeting on Tuesday, the chairman (Mr. J. Falconer) said the most important work the directors had had to deal with since the last general meeting had been the promotion of the act passed last session to enable the company to work the railway by electricity, and to extend the time for paying off the redeemable first debenture stock. The bill also embraced a scheme for re-arranging the finances of the company, and for the appointment of a joint committee, by agreement with the Wirral Railway Co., for enabling the two companies to have a joint system of electric traction. According to the best advice, the result of adopting electric traction would be not only to free the tunnel from the fumes which were so objectionable to passengers, but also to cheapen the cost of working while greatly increasing the service. The difficulties against which they had had to contend with steam traction, and their want of success, would not be experienced with electric traction. This view has been strikingly confirmed by the result of the opening of the Central London Railway—an electric line working under conditions not nearly so favourable as in the case of their line. The Mersey Company had a full-sized railway tunnel of the ordinary type, and they had complete liberty as regarded the construction of their carriages and the electrical plant with which to haul them. If a joint scheme were arranged with the Wirral Company for working the two concerns by electric traction the cost involved was estimated, roughly, at £500,000: that was the amount of the borrowing powers provided for. If they did not come to terms with the Wirral Company, and had to raise the money on their own account, the cost was estimated at about £300,000.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since July 19, 1900). Price of silver 28 1/16d. per oz. (Sept. 27). Consols (2¾ per cent.) 98¼–98⅜ for money, 98 5/16–98 7/16 for account; 2½ per cent. 96¾–97¼ (Sept. 27). Stocks and Shares Continuation Days, Oct. 10 and 24; Ticket Day, Oct. 11; Pay Days, Sept. 28 and Oct. 12; Mining Share Carry-over Days, Oct. 9 and 23.

CHADBURN'S (SHIP) TELEGRAPH CO. (LTD.)—Dividends at the rate of 6 per cent. per annum on the ordinary and preference shares for the half-year ended 30th inst., and payable Nov. 1, are announced.

COMPAGNIE INTERNATIONALE D'ELECTRICITE.—A dividend of 10 per cent. was paid for the year 1899-1900 against 11 per cent. in the previous year.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH CO. (LTD.)—An interim dividend for the quarter ended June 30 of 2s. 6d. per share (tax free), payable on Oct. 15 next, has been declared. The share register will be closed from 6th to 13th prox. inclusive.

EASTERN TELEGRAPH CO. (LTD.)—This company announce the payment on Oct. 15 of a dividend at the rate of 3½ per cent. per annum, less tax, on the preference stock for the quarter ending Sept. 30, and the usual interim dividend of 1¼ per cent. on the ordinary stock, free of tax, in respect of profits for the quarter ended June 30 last. The transfer register will be closed from Oct. 8 to 15 inclusive.

EVERED AND CO. (LTD.)—An interim dividend at the rate of 7½ per cent. per annum for the half-year ended June 30 has been declared.

GLOBE TELEGRAPH AND TRUST CO. (LTD.)—The financial papers announce the declaration of a quarterly dividend of 1s. 9d. per share on the ordinary shares in this company.

ROCKHAMPTON (QUEENSLAND) GAS AND COKE CO. (LTD.)—Dividends at the rate of 7 per cent. per annum on the ordinary and 9 per cent. on the preference shares have been declared. The company has owned for several years a small electricity station on which there was a loss of £143 last year, but no attempt has yet been made by the company to popularise its electric lighting department.

STOCK EXCHANGE NOTICE.—Application has been made to the Stock Exchange committee to appoint a special settling day in and to grant a quotation to the further issue of 5,000 £5 fully-paid shares of the *Telegraph Manufacturing Co. (Ltd.)*.

NOTES.

THE International Electricity Congress, the summarised report of whose proceedings we conclude in this issue, has been the opportunity for the publication of a number of Papers, but it must be confessed that, although some have been of considerable interest, they have been as a whole disappointing. Among the exceptions we may mention three excellent Papers of the "report" or summary order by M. VIOLLE, M. BLONDEL, and M. BLONDEL in conjunction with Capt. FERRIÉ, setting forth respectively the present status of photometry, of the theory and construction of arc and incandescent lamps, and of wireless telegraphy; while Mrs. AYRTON'S contribution to our knowledge of the electric arc was undoubtedly the most important of the actual Papers, and is likely to lead to useful practical results besides advancing a step further towards a complete theory of the physics of this intricate phenomenon.

IN the direction of general resolutions the most noticeable result of the labours of the Congress has been to propose names for the C.G.S. units of magnetic field and magnetic flux. The names "gauss" and "maxwell" will be received with satisfaction, as would be anything tending to perpetuate the memory of these two pioneers. It may be questioned, on the other hand, whether names for units of magnetic field and magnetic flux are necessary at all, for we have been able to do without them for so long; and even if such names are necessary, would it not have been preferable to have adopted the practice followed hitherto, and have given names to more convenient units of greater magnitude, leaving the electrical C.G.S. units without specific titles? In any case it is a matter for regret that in no country will the correct pronunciation of *both* gauss and maxwell be found easy.

IN another column we reprint a letter from Dr. J. A. FLEMING, which appeared in yesterday's *Times*, on recent advances in Marconi telegraphy. Although lacking in technical particulars, the letter is of special interest as giving the authoritative statement of a thoroughly qualified witness, that the isolation of simultaneous messages can be effectively carried out. The technical particulars are promised later, and we hope to furnish them to our readers so soon as they can be disclosed. Meanwhile, we may direct attention to the chief points in Dr. FLEMING'S letter. Evidently the process of syntonising the receivers each to a special wave-tone has been chosen, and is relied on, as the method of producing the satisfactory degree of isolation which Dr. FLEMING describes. It is admitted that this process does not originate with Mr. MARCONI, but the claim is advanced that "no one has given practical proof of possessing a solution of this problem which for a moment can compare with that Mr. MARCONI is now in a position to furnish." We may also call attention to the replacement of the vertical wire by a hollow metal cylinder, a change which removes finally the necessity for high masts in signalling over long distances. We congratulate Mr. MARCONI on the great advance which his lengthy and patient researches have thus rendered possible.

A BRIEF communication by M. GEORGES RHEINS to the Académie des Sciences, abstracted by Mr. FOURNIER in another column of this issue, will be read with interest by both cable makers and users, and will, perhaps, give rise to some interesting "life" experiments on cables. It appears that with both gutta percha and paper insulation the copper, presumably by some sort of electrolytic action, can actually penetrate outwards in such a way as to interfere with the electrical properties of the dielectric. Thus M. RHEINS observed that, in 20 years, copper had soaked through to the surface of a gutta percha cable, and that four years had sufficed for the metal to penetrate into the first layer of paper on a cable insulated with this latter substance. Unfortunately

Digitized by Google

M. Rheins omits from his Paper all reference to the details of the experiments. We are not informed where the cables were laid during their time of probation, nor how the insulation was protected externally. However, it is of value to know that, in certain circumstances, a gutta-percha cable can perish in 20 years through an action hitherto unnoticed, and that even paper insulation is not everlasting. On the other hand, it might be possible to obtain an approximation to Oliver Heaviside's ideal dielectric combining "leakance" and inductance if gutta-percha could be permeated with iron instead of copper, although we fear that in such a case the increased "permittance" or capacity might spoil the effect. But before any definite conclusions can be drawn one way or the other, we must know more of Mr. Rheins' experimental conditions, and, if they have been such as to preclude the possibility of a "mare's nest," the true cause of the effect must be discovered, and an endeavour made to accelerate it on selected test lengths of cable.

Further correspondence appears in our issue this week on the effect of lightning flashes on carbon filaments, a subject which has aroused widespread interest. The coherer theory appears to be largely favoured, though there are not wanting critics who regard this as being too fanciful. A crucial test might be arranged by subjecting a glowing lamp to strong Hertzian radiation, rapidly intermittent. Incidentally, our correspondent, Mr. F. Alex. Taylor, raises the old cry against the name "coherer" and the phrase "decoherence." They are a misnomer and completely misleading phrase; but where can we find better? There is the same trouble about "wireless telegraphy," palpably not wireless. Terms so phonetically convenient stick hard, and are not easily sledge-hammered off by logic.

Prof. Bose has suggested "molecular receiver" as a substitute for "coherer"; but, not unconscious of the comparative inconvenience of a double-barrelled name, he has proposed its contraction to "mol." The latter condemns the former, and both fall irretrievably. Besides, there are other forms of "molecular receiver" affected by radiation—a photographic plate, for example. How are we to discriminate, and what in the name clinches the apparatus as distinctly Hertzian? Arbitrary names usually seem uncouth at the first; usage tones them down. Response to radiation is the most universal characteristic of coherers of all classes. Might they not be termed "responders"? Distinctly, when we remember the entire action that goes on, we see that the apparatus does more than *receive* radiation—it *responds* to it.

The "Twopenny Tube," we know, is buried underground; but it is not yet dead. A writer in *The Times* appears to think it is, and has written its epitaph: "It failed through its success." The world has been told until now that "nothing succeeds like success," a motto more appropriate to the railway in question, wherein success has grown at compound interest. Critics of the new railway are numerous. Some object to the "chopper" system of ticket collection, previously matured by years of experience on the New York "Elevated"; others are sensitive to draughts, more Boreal than Æolian it must be admitted; while others, again, like the writer of epitaphs, want seats guaranteed even in the most crowded of trains. Our own criticism we shall come to presently. In the matter of overcrowding, the obvious remedy is to increase the number of trains during the busiest hours. This change the Central London Railway Co. is fully prepared to adopt so soon as a 2½ minutes' headway can safely replace the existing headway of 5 minutes. Discretion in this respect is the better part of valour, for a disastrous rear collision would do more than anything else to call promptly for an epitaph, of different phraseology.

As an underground railway complete in itself, the "Twopenny Tube" really calls for but little improvement. Where it is most conspicuously defective is in its linkage with other and similar railways, swelling in numbers to form a widespread network beneath the metropolis. A ready opportunity has been narrowly missed to make this a really united network, but there is time yet for the remedy. At present, transference between any one and any other of the three electric railways converging on the vicinity of the Bank can only be made by a double journey to the surface (or nearly so) and down again. To transfer from the "Twopenny Tube" to the City and South London Railway involves two lift journeys and a tedious march through lengthy passages. In the ideal arrangement it would be possible to pass from one line to the other through a passage-way at the low level of the railways. We hope that all future interconnections will be arranged in this manner.

"Twopenny Tube" Appetiser.—An American contemporary states that travel on the "Twopenny Tube" is reputed to develop an appetite in the traveller, the tonic effect being "ascribed to the ozone generated by the electricity." A little ozone evidently goes a very long way.

Carbon Filaments and Lightning Flashes.—Mr. L. S. Levy, has contributed the following letter to the *Electrical World* of Sept. 22:—

In the London *Electrician*, Aug. 31, 1900, some leading remarks are made regarding a phenomenon that was noted in incandescent lamps during an electric display accompanying a storm. I have noted the very same thing, viz., a momentary increase in brightness with each lightning flash, but would look for the explanation not in a coherer effect in the carbon filament, but in the increased voltage of the line, due to resonance. Conditions are not favourable to the ordinary manifestation of the latter condition, but the varying periodicity of the discharge will make them so, though only for an instant.

If we are to accept the statement made by Prof. Elihu Thomson, to the effect that not all lightning discharges are oscillating in character, I am strengthened in my belief, as in several instances the momentary brightening in the lamps was absent.

Paris Exhibition Literature.—The third number of "L'Electricité à L'Exposition de 1900" has been published. It contains complete descriptions of the alternators installed at the Paris Exhibition for the supply of current there, and also of the two German continuous-current machines which are driven by the same engines as the German alternators, and were not included in the previous number describing the continuous-current machines. The present number, which is

Digitized by Google

written by MM. J. A. Montpellier, M. Aliamet and F. Loppé, maintains the excellence shown in its predecessors, and MM. Hospitalier and Montpellier, the editors, as well as Messrs. Dunod, the publishers, are to be congratulated on the manner in which they are attacking the task of describing the electrical features of the Paris Exhibition.

Institution of Civil Engineers.—The Council have, in addition to the medals and prizes given for communications discussed at the meetings of the Institution in the past session, made the following awards in respect of other Papers dealt with in 1899-1900: A "George Stephenson" medal and a Telford premium to L. F. Vernon-Harcourt, M.A. (London); Telford premiums to H. J. S. Heather, B.A. (South Africa); Walter Rosenhain (Cambridge), James Glover, M.A. (Lowton, Lancs.), A. B. Brady (Brisbane), R. C. Farrell (Dunoon), C. F. V. Jackson, B.E. (Sydney); and G. B. Walker (Barnsley). For students' papers: The "James Forrest" medal and a "Miller" prize to C. B. Fox, B.A. (Wimbledon), the "James Prescott Joule" medal and a "Miller" Prize to J. W. Smith (Burton-on-Trent); and "Miller" prizes to B. Humphrey (New Swindon), H. E. O'Brien, B.Sc. (Horwich), H. E. Wimperis, B.A. (Cambridge), and A. H. Morton (Glasgow). The Council have nominated Mr. R. F. Whitehead to the "Palmer" scholarship at the University of Cambridge in succession to Mr. A. H. Kirby, who graduated last June.

Absorption of Hertzian Rays.—Signor Emile Guarini and Lieut. Poncelet have sent us a joint communication on experiments they have made with screens placed between a Wimshurst machine and a coherer. The Wimshurst machine, provided with its usual condensers, emitted Hertz waves which affected the coherer, and the experimenters satisfied themselves that only direct waves need be taken account of, as when a screen was placed between the coherer and the machine, the former was protected. The distance between coherer and machine was a few metres. It was found that the human body, interposed between the machine and the coherer, effectively absorbed the rays whether the body was insulated or not. This might have been expected. On the other hand a thin sheet of iron, which would not screen the coherer under normal conditions, screened it when connected to earth. The writers try to explain the different action of the insulated and earthed iron plate, by the hypothesis that this metal screw "constituted a new radiator acting by induction from the transmitter. The electric waves," they continue, "do not pass a metallic screen, but produce in it induced oscillating currents, which in their turn produce a radiation in space." Earthing the screen prevents this inductive effect, they suggest. We think that the authors should have examined carefully their experimental conditions, and have endeavoured also to reproduce the effect with a different arrangement of apparatus, before putting forward this theory. It is a pity that so much energy is wasted in methodless experiment in a field in which patient and methodical investigation is urgently needed.

Wireless Telegraphy and Earth Connection.—"It is wonderful," says the *Electrical World* of New York, "how much seems to depend upon the earth in Hertzian-wave telegraphy. It is common belief that the earth has little or nothing to do with the matter, and that the air or upper world of ether is all important. On the other hand, however, it is now recognised that transmission can be carried considerably further over the ocean than over the land, and it is believed that the difference is due to the higher conductivity of sea-water. It is even stated that on land the dryness or dampness of the soil noticeably influences the transmission, and apparently from the same cause. It is further stated that Hertzian-wave telegraphy has been a failure in South Africa during the recent war, owing to the general prevalence of bad earth. Not only is good earth in the telegraphic sense difficult to secure, but the long desert plains are most unfavourable to the transmission of electric waves. What is ideally needed for their transmission is a highly conducting level surface over which the waves may run without absorption, being continually reflected. In the absence of such an electric mirror the waves tumble into the earth and become absorbed as well as dispersed. All these conditions seem to point to the ocean as the future scene of utilisation of Hertzian-wave telegraphy. On land we can ordinarily hang or bury our wires and be content. At sea we are unable to maintain metallic communication, and where the ocean begins the opportunity of the wireless telegraph begins also. It is to be hoped that the day may not be far distant when the light-houses along our coasts will also be Hertzian-wave houses and issue signals day and night to the shipping within 50 miles radius. The steamer's mast will then have two functions left—one to hold up flags and the other to hold the antenna."

Recent Advances in Wireless Telegraphy.—The following letter, which we comment on in our editorial notes this week, was contributed by Prof. J. A. Fleming to *The Times* of yesterday's date:—

As the subject of wireless telegraphy has not yet apparently lost interest for the general reader, I venture to ask a little space to make known for the first time some recent achievements by Mr. Marconi which have astonished those who have been allowed to examine them. Every one is aware that in his system of electric wave telegraphy an important feature is the employment of an elevated conductor, which generally takes the form of a wire suspended from a mast. When Mr. Marconi attracted attention by his feat of establishing communication across the Channel without wires, critics raised a not altogether valid argument against its commercial utility, that a wave or signal sent out from one transmitter would affect equally all receivers within its sphere of influence, and hence the privacy of the communication would be destroyed. No one felt the force of this objection more strongly than the distinguished inventor himself, whose original work has caused so many others to attempt to follow in his steps. For the last two years he has not ceased to grapple with the problem of isolating the lines of communication, and success has now rewarded his skill and industry. Technical details must be left to be described by him later on, but meanwhile I may say that he has modified his receiving and transmitting appliances so that they will only respond to each other when properly tuned to sympathy. I am well aware that other inventors have claimed to be able to do the same thing, but I do not fear refutation in saying that no one has given practical proof of possessing a solution of this problem which for a moment can compare with that Mr. Marconi is now in a position to furnish.

These experiments have been conducted between two stations 30 miles apart, one near Poole in Dorset and the other near St. Catherine's in the Isle of Wight. At the present moment there are established at these places Mr. Marconi's latest appliances, so adjusted that each receiver at one station responds only to its corresponding transmitter at the other. During a three days' visit to Poole, Mr. Marconi invited me to apply any test I pleased to satisfy myself of the complete independence of the circuits, and the following are two out of many such tests: Two operators at St. Catherine's were instructed to send simultaneously two different wireless messages to Poole, and without delay or mistake the two were correctly recorded and printed down at the same time in Morse signals on the tapes of the two corresponding receivers at Poole.

In this first demonstration each receiver was connected to its own independent ærial wire hung from the same mast. But greater wonders followed. Mr. Marconi placed the receivers at Poole one on the top of the other, and connected them both to one and the same wire, about 40ft. in length, attached to a mast. I then asked to have two messages sent at the same moment by the operators at St. Catherine's, one in English and the other in French. Without failure each receiver at Poole rolled out its paper tape, the message in English perfect on one and that in French on the other. When it is realised that these visible dots and dashes are the results of trains of intermingled electric waves rushing with the speed of light across the intervening 30 miles, caught on one and the same short ærial wire, and disentangled and sorted out automatically by the two machines into intelligible messages in different languages, the wonder of it all cannot but strike the mind.

Your space is too valuable to be encroached upon by further details, or else I might mention some marvellous results, exhibited by Mr. Marconi during the same demonstrations, of messages received from a transmitter 30 miles away and recorded by an instrument in a closed room merely by the aid of a zinc cylinder, 4ft. high, placed on a chair. More surprising is it to learn that, whilst these experiments have been proceeding between Poole and St. Catherine's others have been taking place for the Admiralty between Portsmouth and Portland, these lines of communication intersecting each other; yet so perfect is the independence that nothing done on one circuit now affects the other, unless desired. A corollary of these latest improvements is that the necessity for very high masts is abolished. Mr. Marconi now has established perfect independent wireless telegraphic communication between Poole and St. Catherine's, a distance of 30 miles, by means of a pair of metal cylinders elevated 25ft. or 30ft. above the ground at each place.

I need not enlarge on the possibilities thus opened out for naval and military purposes. The importance of this practical solution of the problem of independent electric wave telegraphy, in which each wireless circuit is as private as one with a wire, is obvious without comment. My desire is solely to mention the above facts for the benefit of general readers, whose minds will thus perhaps be eased of any doubts lest this brilliant application of electrical discoveries should, like some others, fall short in satisfying the requirements of practical use and be relegated to the region of imperfect inventions or unfulfilled hopes.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Deterioration of Cables.—When a cable is used for transmitting a variable current, characterised by equal fluxes of opposite electricity, it preserves all its electric and organic properties intact. When, however, the current traverses it always in the same direction, the cable, according to G. Rheins, passes through four stages marked by the complete loss of some electric property, and the change of the properties remaining. The order of disappearance is the following: Inductance, capacity, insulation, conductivity. This process of deterioration is due to the slow penetration of the metal of the core into the dielectric, and this penetration appears to be independent of the kind of dielectric, since it is observed both in the case of paper and of gutta-percha. In one case of the latter, used for 20 years, the copper of the core was found to have soaked through to the surface of the insulator. In another case, that of a paper cable in use for four years, the copper was found to have penetrated into the first layer of paper, but not into the second.

[G. Rheins, *Comptes Rendus*, Sept. 10, 1900.]

Resistance of Bismuth.—W. Eichhorn has carried out some interesting investigations of the speed with which bismuth assumes a certain resistance under the influence of a magnetic field. He mounted a bismuth coil on a revolving disc so that at a certain point it passed through a magnetic field. Its instantaneous resistance was measured by means of contact pieces attached to the disc, and the resistances shown at various points when entering or leaving the field were compared with the resistances shown at the same points in a state of rest. Any lag or hysteresis of the resistance would then show itself as a difference of resistance for corresponding points, according to the state of rest or motion. The rate of revolution was 1,000 per minute. A well-marked difference was observed both on entering and leaving the field. On leaving the field the resistance remained too high. This result is specially conclusive. For in the state of rest the resistance was influenced by the heat of the magnetising current, which tended to exaggerate the normal resistance. That the resistance when in motion is still greater shows that the bismuth does not instantaneously lose the high resistance acquired in the maximum field. The difference is constant for any speed of revolution exceeding 500 per minute, but below that rate it increases with the speed. The author calls the phenomenon a viscous hysteresis of resistance.

[W. Eichhorn, *Ann. der Physik*, No. 9, 1900.]

Atmospheric Potential during a Solar Eclipse.—The modern theory of ionisation, or rather of "electronisation," has been applied with considerable success to the explanation of atmospheric electricity. Elster and Geitel suppose that the impact of the ultra-violet rays of the sun upon the upper strata of the atmosphere produces the separation of positive and negative electrons, and that the different velocities of the latter produce an unequal distribution of positive and negative charges in the atmosphere. If that is true, then a temporary cessation of the sun's activity in this respect might produce a well-marked change in atmospheric potential. Such a change was searched for at Pavia by E. Oddone during the total eclipse of the sun on May 28. Unfortunately, the geophysical observatory at Pavia was not in the path of totality, but 8·10*n*ths of the disc were obscured, and a measurable effect could therefore be hoped for. The measurements, taken with a water-dropping collector and Exner electroscope showed a slight increase of positive potential, but it was difficult to dissociate this effect from the effect of moisture. Perhaps some observations hitherto unpublished were taken within the area of totality. In any case, the chances are that the effect of a change in the upper atmosphere would not be felt for some time at the earth's surface.

[E. Oddone, *Rendic. Ist. Lombardo*, 33, 1900.]

Reflection of Cathode Rays.—Two years ago, H. Starke described a study of the diffused reflection of cathode rays, and showed that the reflected rays take their charges with them. He has since repeated the experiments with greater precautions, and has studied more especially the reflective powers of copper and aluminium for cathode rays. Mirrors made of the two metals were placed inside a metallic cylinder through an opening in which the cathode rays entered. A galvanometer connected with the mirror measured the amount of cathode radiation absorbed. The amount reflected and diffused was measured by nearly surrounding the mirror with a second cylinder fitting in the first, and connected with another electrometer. The two metallic cylinders were enclosed in a vacuum together with the cathode furnishing the rays. The mirror was put into two different positions in the cylinder, so as to determine the amount of cathode radiation diffused by the gas itself. The reflective power of aluminium was found to be 28·2, and that of copper 45·5, whatever the velocity of the cathode rays. This ratio is, by the way, very nearly the same as that of the square roots of the atomic weights of the two metals. It would be well to find out whether such a rule would hold good throughout.

[H. Starke, *Ann. der Physik*, No. 9, 1900.]

Ratio of Conductivities.—In view of recent attempts to bring thermal and electrical conduction under the common theory of electrons, the ratio between the two conductivities in question acquires additional interest. E. Grüneisen has therefore examined the influence upon this ratio exerted by certain impurities in copper and iron. He determined the thermal conductivities of four iron bars and three copper bars by projecting a current of steam against their end surfaces, as in Schulze's method, and following the propagation of the heat through the bar by means of a thermo couple, one element of which was the bar itself. In copper, it was found that a very small proportion of arsenic suffices to reduce the thermal conductivity to one-tenth of its value in pure copper. The electrical conductivity is depressed at the same time to one-twelfth of its original value. In iron, the difference is even greater, the electrical conductivity being a great deal more sensitive than the thermal conductivity. Thus the ratio of the former to the latter, which is 1,730 in nearly pure iron, becomes 2,160 (C.G.S.) in an iron bar containing 1·5 per cent. of carbon, 0·19 of manganese, and 0·05 of silicon. The electrons conveying electric charges are evidently more disturbed by foreign bodies than those which convey heat only.

[E. Grüneisen, *Ann. der Physik*, No. 9, 1900.]

Helical Vacuum Discharge.—The new vacuum phenomenon discovered by E. Ruhmer is of considerable interest and is a striking sight. It is best produced in a glass tube 1mm. long and 4cm. wide, exhausted so that a discharge from a 30cm. induction coil just forms a spark of 15cm. through air in preference to the tube itself. When an industrial current at 110 volts pressure is sent through the tube and a Wehnelt interrupter, a thick red stripe traverses the tube from end to end. On reducing the current by suitable resistances, the stripe breaks up into a series of glowing patches. On placing the tube vertical and grasping it round the middle, so that the anode is uppermost, the patches arrange themselves in a spiral, which slowly turns about its axis, making one revolution in about 7sec. The diameter of the screw is about 2·5cm., and the screw is left-handed. Sometimes the diameter is smaller, and then the screw is right-handed, but in both cases the rotation is such that the wave line appears to descend. The point of attachment at the electrodes remains the same. The pitch of the screw varies with the strength of the current and the rate of interruption. The phenomenon has not been hitherto explained, but it has probably some connection with the warm air current rising spirally in the tube.

ELECTROMAGNETIC THEORY.—CXVIII.*

BY OLIVER HEAVISIDE.

(*Continued from page 638.*)

§ 473. Another way of getting Fresnel's wave-speed was described to me by Prof. G. F. FitzGerald. Write the second, or Faraday's circuital law in the form

$$-\operatorname{curl}\mathbf{F}=\mu p\mathbf{H}, \tag{38}$$

and the first, or Maxwell's, in the form

$$\operatorname{curl}(\mathbf{H}-\mathrm{V}c_1\mathbf{Fw})=p\mathbf{D}=p\mathbf{D}_0+p\mathbf{D}_1, \tag{39}$$

where $\mathbf{D}_0$ belongs to the ether, and $\mathbf{D}_1$ is the electrisation or electric polarisation added on by the matter. Then let

$$\mathbf{D}_0=c_0\mathbf{F}, \qquad \mathbf{D}_1=c_1(\mathbf{F}+\mathbf{e})=c_1\mathbf{E}, \tag{40}$$

where $\mathbf{e}=\mathrm{V}\mathbf{w}\mathbf{B}$. These equations give Fresnel's wave speed when w is small, that is, $\mathrm{U}=v+(c_1/c)w$.

It occurred to me that the term $\mathrm{V}c_1\mathbf{Fw}$ should be $\mathrm{V}c_1\mathbf{Ew}$, because in the additional part thus introduced, or $\mathrm{V}c_1\mathbf{ew}$, all the factors are related to the matter. This change makes no difference in the approximate result, and was not objected to. But Prof. FitzGerald believed the above way was equivalent to Lorentz's.

To find Lorentz. After profound research I succeeded in discovering Prof. H. A. Lorentz's "Versuch einer Theorie der electrischen und optischen Erscheinungen in bewegten Körpern," Leiden, 1895. This important application of Maxwell's theory to optical phenomena ought to have been done into English at once to save repetitional labour. Though sad, it is a fact that few Britons have any linguistic talent. This is not due to laziness, but mainly to a real mental incapacity, combined with the feeling that one language is quite enough. Foreigners, on the other hand, seem to be gifted linguists quite naturally, so much so that they have invented a large number of lingos, and are commonly skilled in several at once. Very well; I would say let them give us poor islanders the benefit of their skill, by doing all their best work into English. And why not make English the international scientific language? It would be all the same to the foreigners, and a great boon to Great-Britain-and-Irelanders, and the other English-speaking people.

On examination, I find that Lorentz's equations do lead to the Fresnel wave-speed, and in the above way. As his work is not so well known in England as it deserves to be, I will give a short sketch of Lorentz's way of treating the circuital equations, with reference to the matter in hand, but without any particular confinement in details. I observe with some personal gratification that Lorentz employs Vector Analysis (not Quaternions), and that he works entirely upon the circuital equations and their accessories, without the vector-potential or the Principle of Least Action, which last, in spite of its name, has the remarkable property of increasing the amount of the work to be done.

Let H and F be the magnetic and electric forces in ether away from matter and electrification, then

$$\operatorname{curl}\mathbf{H}=p\mathbf{D}_0=c_0p\mathbf{F}, \tag{41}$$

$$-\operatorname{curl}\mathbf{F}=p\mathbf{B}_0=\mu_0p\mathbf{H}, \tag{42}$$

are the fundamental circuital equations. I think it proper to have two ethereal constants. I do not consider the velocity of propagation to be a fundamental constant. It is a compound idea. Propagation is caused by some properties of the ether, I believe, and all known cases of propagation arise from the interaction of two properties. Lorentz has $\mu_0=1$, or ignores μ altogether, and $c_0=\mathrm{V}^{-2}$. Of course I also rationalise his units.

If there is electrification, measured by its volume density $\rho=\operatorname{div}\mathbf{D}_0$, the above equations suffer no change unless the electrification moves. Let the velocity of ρ be $\mathbf{u}+\mathbf{w}$, where the part w is constant, the same for all the electrification, and u is variable. As is well-known, $\rho(\mathbf{u}+\mathbf{w})$ is a part of the Maxwellian true current, the missing link in the chain of the displacement current $p\mathbf{D}_0$. So

$$\operatorname{curl}\mathbf{H}=p\mathbf{D}_0+\rho(\mathbf{u}+\mathbf{w}) \tag{43}$$

takes the place of (41). The reference space in these equations is the ether itself, supposed fixed. But let the reference space have the same common motion w as the matter carrying the electrification. Let p' be the time differentiator for the moving matter, then

$$p'=p+\mathbf{w}\nabla \tag{44}$$

shows its connection with p. The circuital equations become

$$\operatorname{curl}\mathbf{H}=(p'-\mathbf{w}\nabla)\mathbf{D}_0+\rho(\mathbf{u}+\mathbf{w}), \tag{45}$$

$$-\operatorname{curl}\mathbf{F}=(p'-\mathbf{w}\nabla)\mathbf{B}_0. \tag{46}$$

Now, in general,

$$\operatorname{curl}\mathrm{V}\mathbf{w}\mathbf{B}=\mathrm{V}\nabla\mathrm{V}\mathbf{w}\mathbf{B}=\mathbf{w}.\nabla\mathbf{B}+\mathbf{B}\nabla.\mathbf{w}-\mathbf{B}.\nabla\mathbf{w}-\mathbf{w}\nabla.\mathbf{B}, \tag{46A}$$

(Vol. I., p. 200, equation 181).

Applying to (46), we have

$$-\mathbf{w}\nabla.\mathbf{B}_0=\mathrm{V}\nabla\mathrm{V}\mathbf{w}\mathbf{B}_0,$$

and applying to (45),

$$\mathbf{w}.\nabla\mathbf{D}_0-\mathbf{w}\nabla.\mathbf{D}_0=\mathrm{V}\nabla\mathrm{V}\mathbf{w}\mathbf{D}_0,$$

so (45), (46) become

$$\operatorname{curl}(\mathbf{H}-\mathrm{V}\mathbf{w}\mathbf{D}_0)=p'\mathbf{D}_0+\rho\mathbf{u}, \tag{47}$$

$$-\operatorname{curl}(\mathbf{F}+\mathrm{V}\mathbf{w}\mathbf{B}_0)=p'\mathbf{B}_0, \tag{48}$$

when we travel with the matter. The velocity w may be imagined to be the translational velocity of the earth through the ether at the place in question, it being assumed that the ether is stagnant. Lorentz makes a further transformation for the consideration of aberrational questions, but that is not wanted here. What is wanted is the introduction of the electric moment or the electrisation in a non-conducting material. There is no volume electrification, owing to molecules being equally endowed with positive and negative ions. These ions are displaced under the action of electric force, producing a sort of polarisation; and the first approximation is to assume an equilibrium theory between the moving force on an ion and the displacement. This takes no count of inertia, and the resultant effect is to make the electrisation simply proportional to the moving force. That is

$$\mathbf{D}_1=c_1\mathbf{E}=c_1(\mathbf{F}+\mathbf{e}), \tag{49}$$

where $\mathbf{e}=\mathrm{V}\mathbf{w}\mathbf{B}_0$, is the result. Perhaps the averaging is the obscurest part of the process. The moving force on ρ at a point is $\rho\mathbf{E}$, not $\rho\mathbf{F}$, the additional part $\rho\mathbf{e}$ being Maxwell's electromagnetic force on the current element $\rho\mathbf{w}$.

The circuital equations (47), (48) therefore become

$$\begin{aligned}\operatorname{curl}(\mathbf{H}-\mathrm{V}\mathbf{w}\mathbf{D}_0)&=p'(\mathbf{D}_0+\mathbf{D}_1),\\ &=p'(c\mathbf{F}+c_1\mathbf{e}),\\ &=p'(c\mathbf{E}-c_0\mathbf{e}),\end{aligned} \tag{50}$$

$$-\operatorname{curl}(\mathbf{F}+\mathrm{V}\mathbf{w}\mathbf{B}_0)=p'\mathbf{B}_0. \tag{51}$$

These are the equations employed by Lorentz for a moving dielectric. But I think it is somewhat plainer to let the reference space be the fixed ether. To transform, put $p'=p+\mathbf{w}\nabla$, and use (46A), or rather the special simpler forms following it. We get

$$\begin{aligned}\operatorname{curl}(\mathbf{H}-\mathrm{V}\mathbf{D}_1\mathbf{w})&=p\mathbf{D}=p(\mathbf{D}_0+\mathbf{D}_1),\\ &=p(c\mathbf{F}+c_1\mathbf{e}),\end{aligned} \tag{52}$$

$$-\operatorname{curl}\mathbf{F}=p\mathbf{B}_0=\mu_0p\mathbf{H}, \tag{53}$$

Or, in terms of E and H,

$$\operatorname{curl}(\mathbf{H}-\mathrm{V}\mathbf{D}_1\mathbf{w})=p(c\mathbf{E}-c_0\mathbf{e}), \tag{54}$$

$$-\operatorname{curl}(\mathbf{E}-\mathbf{e})=p\mu\mathbf{H}. \tag{55}$$

Perhaps the most significant form is got by taking out the $\mathrm{V}\mathbf{D}_1\mathbf{w}$ in (52). Then

$$\operatorname{curl}\mathbf{H}=p\mathbf{D}_0+p'\mathbf{D}_1, \tag{56}$$

$$-\operatorname{curl}\mathbf{F}=p\mathbf{B}_0, \tag{57}$$

express the relations. As the ether is supposed to be stationary the time differentiator is simply p for $\mathbf{D}_0$. But the matter moves at speed w, so the time differentiator is p' instead. The distinction is most important, and the functions of p and p' must not be confounded. In the other equation (57), $\mathbf{B}_0$ belongs to the ether, the matter being regarded as unmagnetisable, so the time differentiator is p simply. In this way of regarding (56), (57) we can eliminate the ionic hypothesis, if we can trust that $\mathbf{D}_0$ and $\mathbf{D}_1$ can be separated in the manner assumed.

* All rights are reserved.

Digitized by Google

Lorentz deduces the wave speed from equations equivalent to (50), (51) only after a transformation of variables, including a changed time variable, making the zero of time different for different parts of space. But there is no need for this complication. The mathematics of plane waves is quite simple. Thus, using (52), (53), let w||z, F||x, H||y. They reduce to

$$-\Delta\{H + c_1 w(F - w\mu_0 H)\} = p(cF - c_1 w\mu_0 H), \quad (58)$$

$$-\Delta F = \mu_0 pH, \quad (59)$$

where Δ is d/dz, and the quantities are now all scalars.

Also $p = -U\Delta$, U being the wave speed; so

$$H + c_1 w(F - w\mu_0 H) = U(cF - c_1 w\mu_0 H), \quad (60)$$

$$F = \mu_0 UH, \quad (61)$$

giving the quadratic

$$U^2 - 2U\frac{c_1}{c}w = v^2 - \frac{c_1}{c}w^2, \quad (62)$$

where $\mu_0 c v^2 = 1$, and, therefore, approximately

$$U - v = \frac{c_1}{c}w, \quad (63)$$

the required result.

That the moving force on ρw due to its motion in the field B_0 is ρe may be most simply seen thus. The magnetic force due to ρw is the ordinary magnetic force of a current element. The moving force on a magnetic pole in its field is therefore known. Conversely, the force on ρw due to the pole is known. It is the ρe in question. That the pole gives a special kind of magnetic field is immaterial, because it is only the value of B_0 at ρ that is concerned.

But I think the above theory is possibly too simple to be true. In the first place, can the optical result be considered to be so well established as to make it be necessary to get the Fresnel wave-speed? And, if so, is it proper that the result should come out direct from elementary equations which take no count of dispersion? There is a very wide difference between light vibrations, billions per second, and those concerned in long waves. The above is really a propagational theory, without any reflex actions. On the other hand, U should strictly be the speed of a simply periodic wave-train, itself the resultant of the forward and backward actions. Now it is true that when U does not vary much within a given range of frequency, any wave which is compounded of simply periodic waves within that range is propagated with little distortion, so that a simple pulse theory is approximately true. But when U varies very widely with the frequency, and the arbitrary wave when analysed involves widely discrepant values of U, for example, an impulsive wave itself, an impulsive theory cannot be even approximately true. For this reason I conceive that a more proper theory should be of a secondary character, involving the differential connection between the ethereal disturbance and the internal motions.

And yet it is suggested that the relations (56), (57) may be proper for long waves. But then the effect of magnetisation is not exhibited. If the above reasoning about the meaning of the time differentiators is correct, independently of the ionic hypothesis, it will be equally correct to extend them to

$$\text{curl } H = pD_0 + p'D_1, \quad (64)$$

$$-\text{curl } F = pB_0 + p'B_1, \quad (65)$$

where the new B_1 is the magnetisation, existent when μ differs from μ_0, and of course assumed to be of elastic character. The question then arises as to the relation of D_1 to F, and B_1 to H. If we write

$$D_1 = c_1(F + e), \quad (66)$$

$$B_1 = \mu_1(H + h), \quad (67)$$

it is still matter for argument whether e should be the former VwB_0, or should become VwB, using the complete induction. And as regards h, whether it should be VD_0w, or VDw, or existent at all. In the theory of a movable ether of variable c and μ, the variable parts representing matter, everything can be done symmetrically. But with matter moving through ether, and special hypotheses in connection therewith, there would appear to be no longer a necessity for symmetry.

Prof. FitzGerald says there are electrons, but there are no magnetons, therefore there will be a want of symmetry, other than that arising from putting zero for quantities which might exist. But I think some salt is required here. For, first, it is known not that there are no magnetons, but rather that if there be any, they are in pairs like the ions, and do not dissociate as far as can be concluded from $\nabla B = o$. Next, granting that there are no real magnetons, the theory of the magnetic shell remains. It shows that a closed electric current, which may consist of moving electrons, may be replaced by a double sheet of magnetons so far as external magnetic force is concerned. Thirdly, there are considerations concerning space and time variation of vectors which are quite independent of the physical nature of the vectors. So, altogether, I think it will be wise not to be overhasty in rejecting terms in the circuital equations because magnetons do not exist. Let us try to keep to symmetry to aid understanding any want of symmetry that may be forced upon us by special hypotheses. Say, however,

$$e = nVwB_0, \qquad h = mVD_0w, \quad (68)$$

where m and n are numerics. This will give considerable latitude. What is now the wave-speed?

First, considering a plane wave travelling the same way as w, (64), (65) make

$$-\Delta(H + D_1 w) = pD, \quad (69)$$

$$-\Delta(F + B_1 w) = pB, \quad (70)$$

and therefore

$$H + D_1 w = UD, \quad (71)$$

$$F + B_1 w = UB. \quad (72)$$

Now introduce (66), (67), with the meanings given by (68), we get

$$H + c_1 w(F - wn\mu_0 H) = U(cF - c_1 wn\mu_0 H), \quad (73)$$

$$F + \mu_1 w(H - wmc_0 F) = U(\mu H - \mu_1 wmc_0 F), \quad (74)$$

which give U for any value of w. Neglecting squares, the quadratic is

$$U^2 - Uw\left[\frac{c_1}{c}\left(1 + n\frac{\mu_0}{\mu}\right) + \frac{\mu_1}{\mu}\left(1 + m\frac{c_0}{c}\right)\right] = v^2; \quad (75)$$

where $c = c_0 + c_1$, $\mu = \mu_0 + \mu_1$, and $\mu c v^2 = 1$. That is

$$\frac{U - v}{w} = \frac{c_1}{2c}\left(1 + n\frac{\mu_0}{\mu}\right) + \frac{\mu_1}{2\mu}\left(1 + m\frac{c_0}{c}\right). \quad (76)$$

To revert to the former case, $\mu_1 = 0$, and $n = 1$. But if both m and n are unity, then

$$\frac{U - v}{w} = \frac{c_1}{2c}\left(1 + \frac{\mu_0}{\mu}\right) + \frac{\mu_1}{2\mu}\left(1 + \frac{c_0}{c}\right); \quad (77)$$

and if we employ e = VwB, h = VDw as another extreme case, then $n = \mu/\mu_0$ and $m = c/c_0$, producing

$$U - v = \left(\frac{c_1}{c} + \frac{\mu_1}{\mu}\right)w. \quad (78)$$

Here magnetisation acts similarly to electrisation. Notice that this way of introducing μ_1 allows the coefficient of w to be greater than unity. Then the speed of the wave is increased from v to more than $v + w$ by moving the matter at speed w. This is not impossible, however improbable it may appear.

If we ask how still to obtain Fresnel's wave-speed when μ_1 is finite, examination of (76) shows that $m = -1$ will do it, along with the former $n = +1$. But if $n = \mu/\mu_0$, so as to use the full e, then we require $m = -c/c_0$. But it seems very unlikely that μ_1 should have no influence on the wave-speed.

There are many other ways of modifying the circuital equations so as to always lead to Fresnel's wave-speed when $\mu_1 = 0$, but it is of no use discussing them without some particular reason.

In § 471 above I referred to Dr. Larmor's investigation of the wave-speed. He has kindly asked me to delete the § 87 of his stimulating work "Ether and Matter," being convinced of its erroneousness, and has referred me to his § 73 later on. There is no investigation of the wave-speed there, but on making the necessary reductions I find (subject to an indeterminateness) that the general equations there given do lead to

Digitized by Google

Fresnel's speed, and in the same way as Lorentz's. But there is some indefiniteness about the meaning of the vector (α, β, γ), which he identifies with Maxwell's magnetic force, so I give the equations here in vectorial form and rationalised, that the matter may be made more distinct.

Let $(P, Q, R) = \mathbf{E}$; $(a, b, c) = \mathbf{B}$; $(p, q, r) = \mathbf{w}$. Then Larmor's second circuital law is

$$-\operatorname{curl}(\mathbf{E} - \mathbf{e}) = \dot{\mathbf{B}}, \qquad \mathbf{e} = \mathbf{V}\mathbf{w}\mathbf{B}. \tag{79}$$

This requires no remark.

Let $(A, B, C) = \mathbf{I}$; $(A_1, B_1, C_1) = \mathbf{I}_1$; $(A_0, B_0, C_0) = \mathbf{I}_0$; $(u, v, w) = \mathbf{J}$; $(f, g, h) = \mathbf{D}_0$; $(f', g', h') = \mathbf{D}'$; $(f'', g'', h'') = \mathbf{D}''$; $(f'_0, g'_0, h'_0) = \mathbf{d}_0$; $(\alpha, \beta, \gamma) = \mathbf{H}$. Then Larmor's first circuital law is

$$\operatorname{curl}\mathbf{H} = \mathbf{J}, \tag{80}$$

where J is what he terms Maxwell's total current

$$\mathbf{J} = \sigma\mathbf{E} + \mathbf{w}\rho + p c_0(\mathbf{E} - \mathbf{e}) + p(c_1\mathbf{E} + \mathbf{d}_0) \tag{81}$$

i.e., the sum of the conduction current, convection current, rate of time increase of the ethereal electric displacement, and ditto of the material electric displacement. For it is given that

$$\mathbf{J} = \sigma\mathbf{E} + \mathbf{w}\rho + \dot{\mathbf{D}}'', \qquad \mathbf{D}'' = \mathbf{D}_0 + \mathbf{D}' \tag{82}$$

$$\mathbf{D}_0 = c_0(\mathbf{E} - \mathbf{e}) = c_0\mathbf{F}, \qquad \mathbf{D}' = \mathbf{d}_0 + c_1\mathbf{E}. \tag{83}$$

Here w is the speed of the matter and of ρ the electrification, and $\mathbf{d}_0$ is intrinsic electrisation, analogous to $\mathbf{I}_0$, which is intrinsic magnetisation.

Now as regards H, it is given that

$$\mathbf{H} = \mathbf{B} - \mathbf{I}_1, \qquad \mathbf{I}_1 = \mathbf{I} + \mathbf{V}\mathbf{D}'\mathbf{w}, \qquad \mathbf{I} = \mathbf{I}_0 + \kappa\mathbf{H}, \tag{84}$$

which lead to

$$\mathbf{H} = \mathbf{B} - \mathbf{I}_0 - \kappa\mathbf{H} - \mathbf{V}\mathbf{D}'\mathbf{w}. \tag{85}$$

There are no μ's; that is, the units are "electromagnetic," only rationalised. Remembering this, we have in Maxwell's theory

$$\mathbf{H} = \mathbf{B} - \mathbf{I}_0 - \kappa\mathbf{H}, \tag{86}$$

because $1 + \kappa = \mu$ ("electromagnetic," numerics). This makes $\mathbf{V}\mathbf{D}'\mathbf{w} = 0$, which is obviously not meant. On the other hand, if we ignore (86), and use only (85), we express H in terms of B and $\mathbf{V}\mathbf{D}'\mathbf{w}$; viz.,

$$(1 + \kappa)\mathbf{H} = \mathbf{B} - \mathbf{V}\mathbf{D}'\mathbf{w}. \tag{87}$$

Perhaps this is not meant either. It occurs to me to suggest that the H in equation (80) is not meant for Maxwell's H; call it H′ instead, and then in (85) we shall have H′ on the left side and H, subject to (86), on the right side. This will give

$$\operatorname{curl}(\mathbf{H} - \mathbf{V}\mathbf{D}'\mathbf{w}) = \mathbf{J}, \tag{88}$$

which I think it probable is what Dr. Larmor really means. Because, transferring $\mathbf{V}\mathbf{D}'\mathbf{w}$ to the other side, this equation is the same as

$$\operatorname{curl}\mathbf{H} = \sigma\mathbf{E} + \rho\mathbf{w} + p\mathbf{D}_0 + p'\mathbf{D}', \tag{89}$$

which is equivalent to Lorentz's equation, with the addition of conduction current and intrinsic displacement; because D′ reduces to $\mathbf{D}_1$ when $\mathbf{d}_0 = 0$.

It took some trouble to effect this reconciliation, and I could wish that Dr. Larmor had himself brought his work into line with that of other people; but as he has not done so, he may perhaps be grateful to me for trying to do it. If, however, I have not correctly interpreted his (α, β, γ) or H or H′, in the above way, I do not see how to harmonise matters. I should call curl H the total current, as in (89); not the J in (80).

(To be continued.)

Charing Cross, Euston, and Hampstead Railway.—At a meeting held at the Charing Cross Hotel, last Friday, the undertaking of the Charing Cross, Euston, and Hampstead Railway Co. was formally transferred to Mr. Charles T. Yerkes, of New York, and the gentlemen associated with him in this London electric railway scheme.

A UNIVERSAL CAREY-FOSTER BRIDGE.

BY CHARLES V. DRYSDALE, B.SC.

The Carey-Foster method of comparing resistances has long been known, and has been almost universally adopted for the standardisation of coils of values from a tenth of an ohm upwards. Of recent years, however, resistances of much lower values—down to one ten-thousandth of an ohm—have been used, principally in connection with the measurement of large currents by potentiometer methods. As the Carey-Foster method is undoubtedly by far the most accurate method of standardising coils, the author was led some five years ago to extend this method for use with low resistances. This was accomplished by using the principle of the Kelvin

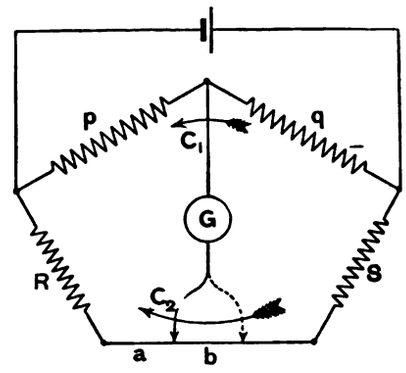

FIG. 1.

double bridge—*i.e.*, of employing a second pair of ratio coils connected across the junction between the resistances. The slide-wire was then removed from its ordinary position between the coils and introduced between the ordinary ratio coils. It will be well, first, to say a few words as to the theory of the method.

Fig. 1 shows the connections of the ordinary Carey-Foster bridge, where R and S are the resistance to be tested and the standard coil respectively, and p and q the approximately equal ratio coils. As is well known, balance is obtained by moving the slide-wire contact when R and S are in the positions shown, and again when they are interchanged. The difference between the resistances R and S in then equal

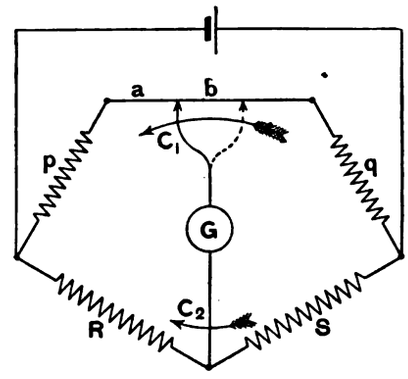

FIG. 2.

to the resistance of the slide-wire between the points of contact, independently of the values of the ratios. For if C_1 is the current passing through p and q, and C_2 that through R and S, we have at first

$$C_1 p = C_2(R + a), \text{ or } R + a = (C_1/C_2)p,$$

where a is the resistance of the slide-wire, including any contact resistance, up to the point of balance.

On interchanging R and S we have in the same way $S + a + b = (C_1/C_2)p$, the ratio of C_1 to C_2 remaining the same, as the total value of the resistance is not altered. Hence $R + a = S + a + b$, and $R - S = b$, as stated.

Let us now suppose that the slide-wire is introduced between p and q instead of between R and S, as in Fig. 2.

Digitized by Google

Then we have $R = C_1/C_2(p+a)$, and on interchanging R and S, $S = C_1/C_2(p+a+b)$.

Hence, $R - S = \left(\frac{C_1}{C_2}\right)b = \frac{R+S}{p+q+r}b$, where r is the total resistance of the slide-wire.

It will thus be seen that the difference of the resistances is now expressed as the resistance of the wire between the points of contact, multiplied by a factor depending on the resistances of the coils and wire. This apparently introduces more complexity into the method, but in practice it makes very little difference. The value of the slide-wire resistance is always found practically by determining the length of the wire corresponding to a known alteration in the difference between R and S, so that it is equally easily determined in either case. Moreover, if the slide-wire resistance r is small in comparison with $p+q$, as it usually is in practice, it will be seen that the bridge will give directly the *percentage* difference in the resistances of the coils instead of the *absolute* difference, thus saving a small amount of calculation. Further, since only two contacts have now to be interchanged instead of four, a much simpler commutator can be used and the number of mercury contacts may be reduced.

Fig. 3 shows the only modification necessary to make the bridge suitable for the comparison of low resistances. As is well known standards of low resistance are provided with four terminals, two for connection to the current-carrying circuit, and two "potentiometer terminals," between which the P.D.

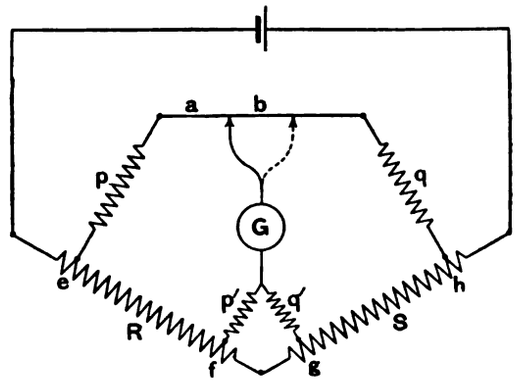

Fig. 3.

can be measured. The resistance of the arrangement is then defined as the ratio of the P.D. between the potentiometer terminals to the current flowing through the arrangement.

For comparing these standards they are connected in series by their current terminals exactly as with ordinary resistances. The ratio coils p and q with their slide-wire, however, span across the two extreme potentiometer terminals e and h as shown in Fig. 3, instead of between the current terminals, while a second pair of approximately equal ratio coils p' and q' are connected across the inner potentiometer terminals f and g as shown. The galvanometer is connected between the junction of the coils $p'q'$ and the slide-wire contact, or virtually between the "electrical centre" of the contact resistance and the slide-wire. In this case if the connections between R and S and the ratio coils are interchanged the same formula applies as in the last case. For if x is the resistance between the terminals f and g including the contact resistance we have:—

$$R + \frac{p'}{p'+q'}\frac{x(p'+q')}{p'+q'+x} = R + \frac{p'x}{p'+q'+x} = \frac{C_1}{C_2}(p+a),$$

and on interchanging

$$S + \frac{p'x}{p'+q'+x} = \frac{C_1}{C_2}(p+a+b),$$

hence $R - S = (C_1/C_2)b$, as before.

In practice it is not usually necessary to interchange the connections with the inner ratio coils p' and q' since the contact resistance x is usually very small, and the ratio coils used with a Carey-Foster bridge are pretty closely equal as a rule. It can be easily seen whether reversal of these coils is necessary, by obtaining balance on the slide-wire and observing whether it is disturbed on interchanging the ratios, but in the author's experience the interchanging of these ratios has been found unnecessary.

A word should be said as to the resistance of the connections. These connections may be divided into two classes, those which are interchanged with the coils, *i.e.*, are between the coils and the commutating device, and those which are not interchanged. The latter have obviously no effect, as their resistance is added to each of the coils in turn. The former do affect the result, and consequently their resistance should be made as low and as nearly identical as possible on the two sides of the bridge.

Construction of the Universal Bridge.—Before describing the bridge which the author has used, it may be well to show that the existing forms of Carey-Foster bridge can be easily

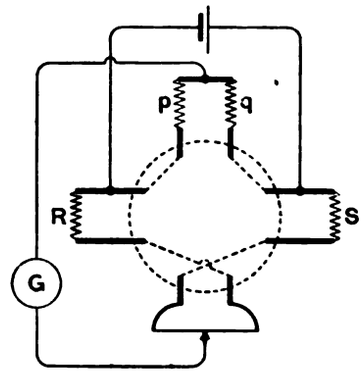

Fig. 4.—Ordinary Carey-Foster Bridge.

modified to admit of low resistance comparison. Fig. 4 shows a diagram of the Nalder form of bridge which has been extensively adopted, the dotted circle representing the commutator, and the dotted straight lines the commutator connections. On turning this commutator half round the resistances R and S are interchanged. In order to convert such a bridge all that is necessary is to introduce a second pair of ratio coils, p and q, between the commutator and slide wire as shown. If the resistances are connected as in the diagram the battery being directly connected to the resistances, it will be seen that the arrangement is electrically equivalent to Fig. 3 and that the interchanging of the connections is

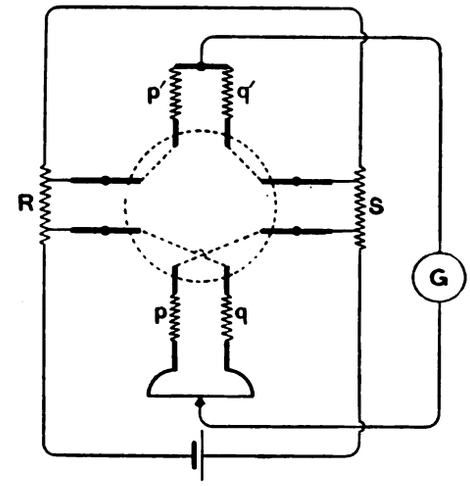

Fig. 5.—Ordinary Carey-Foster Bridge converted for Low Resistance Measurement.

exactly that required. In order to use the bridge for ordinary resistance measurements, the gaps shown bridged by p and q can be simply short circuited by copper connectors dipping into the same cups. It will be seen also that if two extra battery terminals are fixed as shown, the bridge can always be used either with the slide-wire between the coils in the ordinary way, or with it between the ratios, which is more convenient when percentage differences are required.

The design of the bridge which the author has employed is due to Mr. A. D. Hughson, who has had a long experience of

Digitized by Google

accurate resistance work, and who independently suggested the connection of the slide-wire between the ratio coils, with the object of simplifying the commutator.

In Fig. 5 is shown a diagram of this bridge, while the photographs illustrate its construction. The main features in which it differs from existing types of bridge may be enumerated as follows :—

(*a*) The copper connecting bars are all mounted *beneath* the ebonite base, and have mercury cups projecting through so as to be level with the surface of the ebonite. This makes it perfectly easy to keep the ebonite clean and free from mercury, which usually lodges between the bars. It also most effectively prevents any creeping of the mercury over the bars.

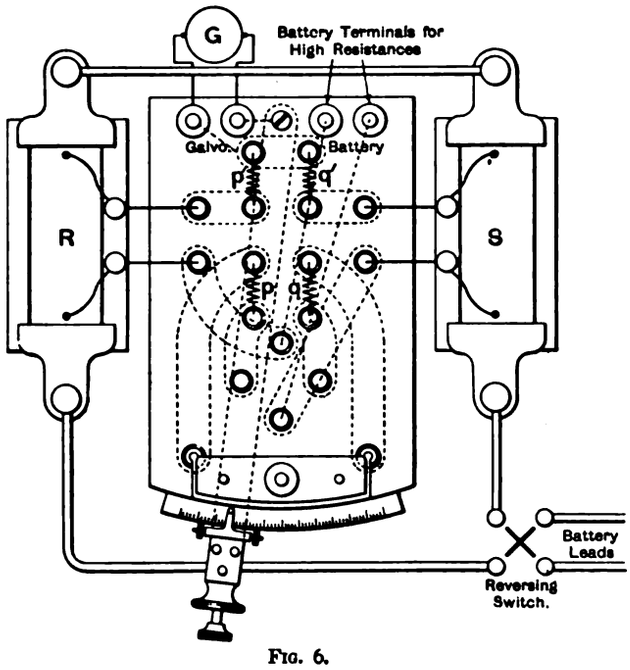

FIG. 6.

(*b*) The slide-wire is connected between the ratio coils in all cases, as in Fig. 2, thus enabling the commutator to be made with four instead of eight contacts.

(*c*) Arrangements are made for the second pair of ratio coils required for low-resistance work to stand in mercury cups just behind the main ratio coils. When these ratios are not required their place is taken by an ebonite disc having two short-circuiting copper connectors, which drop into the same cups. To convert from an ordinary to a low-resistance bridge all that is necessary is to withdraw the disc and stand the ratio bobbin in its place.

(*d*) To gain greater accuracy of reading the sliding contact is mounted on a radial arm so as to move very freely, even when the observer is sitting

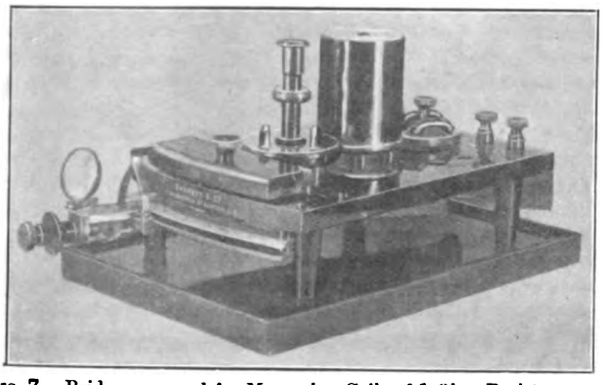

FIG. 7.—Bridge arranged for Measuring Coils of 1 Ohm Resistance and upwards.

at arm's-length from it. This avoids heating of the coils by radiation from the observer's body, and is of considerable importance in practice. The slide-wires are therefore mounted on curved ebonite blocks, and drop on pins on the bridge so as to be easily interchanged. A vernier is provided by which it is possible to read as accurately on short wires as it is usually possible to do with long wires. Short wires are to be preferred in practice as being generally more uniform, less likely to slacken or get damaged, and less liable to temperature differences between the ends. The vernier is read by a universally mounted lens. Considerable care has been devoted to securing a perfectly even pressure between the contact and slide-wire, and to make both the contact and wire of the same material, to avoid thermo forces as much as possible. The importance of these latter points can only be appreciated by those who have had experience in accurate resistance measurement, and it may be at once said that these improvements have rendered it possible to work conveniently to an accuracy of one part in a million when comparing ordinary 1 ohm coils. The sensitiveness indeed is such with a good Kelvin galvanometer that even with a platinoid slide wire $\frac{1}{4}$in. thick hand adjustment is not sufficient to get perfect balance, and it is proposed to fit a clamp and tangent screw to the sliding contact.

Care has of course been taken to eliminate contact errors by making the bars of as nearly as possible identical section and length on both sides of the bridge. Any residual error can be easily determined by taking readings with short-circuited contacts.

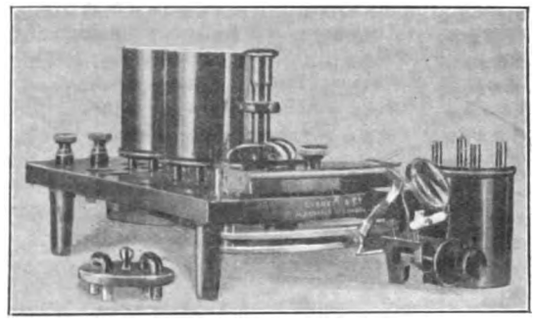

FIG. 8.—Bridge arranged for Low Resistance Measurement.

In a further article the author proposes to give an account of some tests which he has been recently conducting with some specially designed resistance coils, in which he has combined greater possibility of permanence and high-radiating power with an almost negligible temperature coefficient and an electrical means of determining the temperature. It will be seen from these tests that the accuracy claimed for the bridge is justified, and although this may seem almost useless

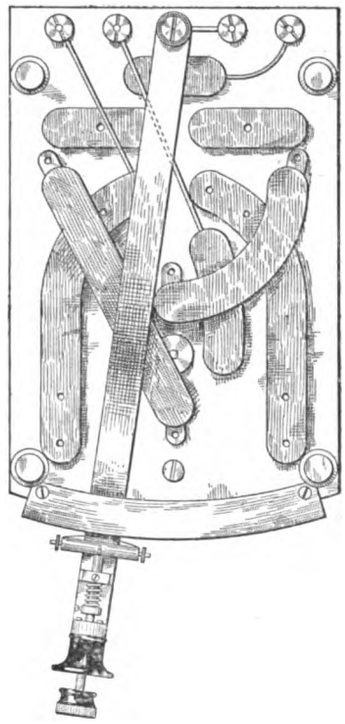

FIG. 9.—General View of Connections from below.

refinement, there are many cases in which it is of great value to determine small differences of resistance with accuracy. It is further proposed to say a few words as to the methods employed in building up and subdividing resistances from a single standard coil.

In conclusion, the author would like to point out that this bridge is preferable for standardising low resistances to any existing form of bridge or potentiometer. In all existing Kelvin bridges, or low resistance measurers, the standard

Digitized by Google

consists of a platinoid or other wire, the uniformity of which is rarely satisfactory. Moreover, in testing low resistances it is of great importance to use the full working current both for sensitiveness and to get the normal conditions of temperature. This is generally impossible with a standard wire, as it will rarely carry more than a small fraction of the current taken by a properly designed low resistance standard without overheating. In the new bridge of course the full working current can be used without any difficulty. It is only necessary to be careful that the ratio coils have a resistance of about a thousand times that of the resistance tested, so as to avoid sensible distortion of the stream lines and equi-potential surfaces in the resistance. The advantage over the potentiometer is apparent in the fact that with the bridge method the current can be reversed at each reading, thus eliminating any thermo-electric effects. This cannot obviously be done with the potentiometer.

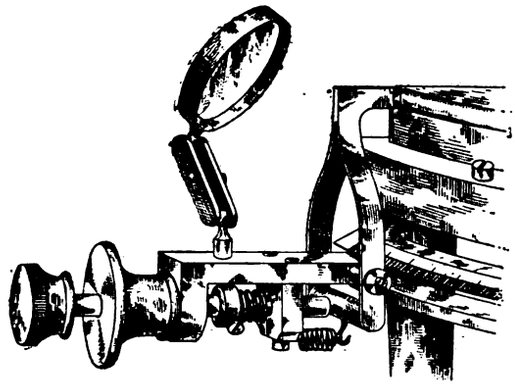

FIG. 10.--Details of Slide-wire Contact.

The bridge illustrated in the photographs was made for the author, for the laboratories of the Northampton Institute, by Messrs. Everett & Co., London, and has been found in every way satisfactory.

THE PARIS EXHIBITION.—VIII.*

(BY OUR SPECIAL CORRESPONDENT.)

Another compounded alternator is one exhibited by the firm of Bréguet. It is a three-phase machine, designed for 2,200 volts at 220 amperes for each phase on a circuit with a power factor of 0·8, and it runs at 250 revs. per min. and 50∿ per sec. frequency. The compounding, which is intended to maintain the pressure at the alternator terminals constant, whatever the current and whether it be useful or wattless, is effected by a special exciter as in the last machine described, in combination with a transformer. The alternator has a rotating field magnet with 24 poles, and its fixed armature resembles that of any other 24-pole, three-phase alternator.

The exciter has to generate continuous current when excited with alternating current, but M. Boucherot, the designer of the machine, has solved the problem in a different way to that employed by M. Leblanc in the Grammont exciter described in my last article. Fig. 47 shows the principle adopted in the design of the exciter. Suppose R in this figure to be an iron ring provided with two windings, the sections of which, instead of each having the same number of turns, are given each a number of turns varying round the circumference in accordance with a sine law, and connected to the commutator by one of the methods shown in Fig. 48 or Fig. 49. Returning to Fig. 47, we shall, for instance, have at B a group of $n \cos k\phi$ turns in series with a group at C of only $n \sin k\phi$ turns. Suppose this ring placed as rotor within a double rotatory field arranged as dotted in Fig. 47, this field rotating in the direction of the arrowhead with a speed ω. Finally, let the armature be turned in the same direction with a speed Ω. It can be shown that if the relation between these speeds be $\omega = -k\Omega$, a continuous current can be taken from brushes placed at A and A′ in the figure. The angle between these brushes is $\psi = \frac{\pi}{k+1}$, and the E.M.F. of the current so obtained

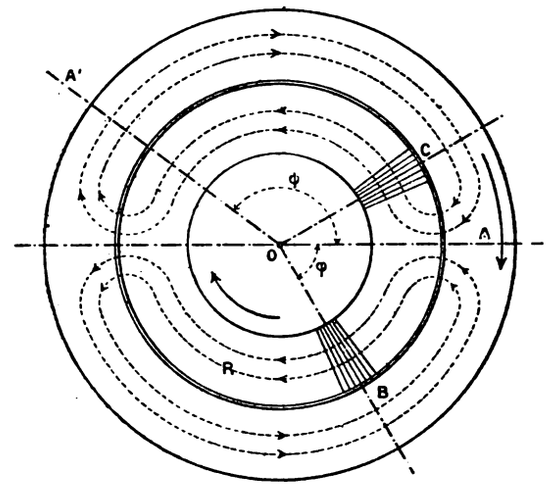

FIG. 47.—PRINCIPLE OF THE BOUCHEROT EXCITER.

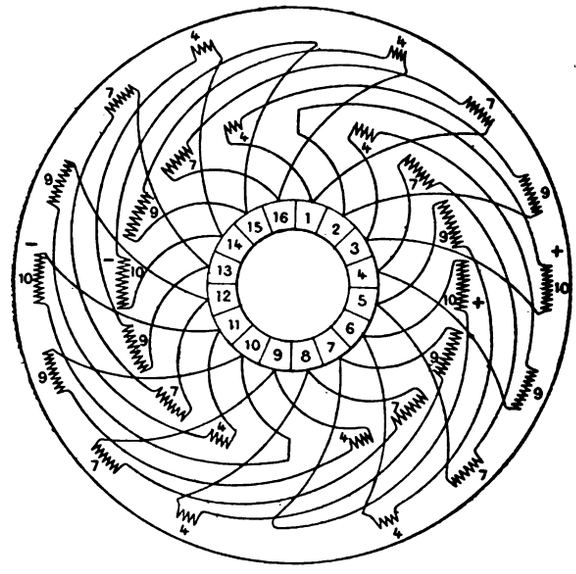

FIG. 48.—WINDING OF ARMATURE OF BOUCHEROT EXCITER FOR $k=1$.

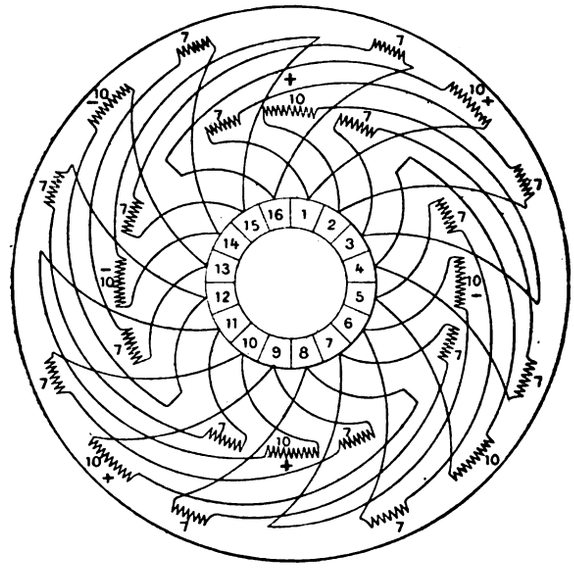

FIG. 49.—WINDING OF ARMATURE OF BOUCHEROT EXCITER FOR $k=-2$.

is $E = 2ne\Omega$, where e is a constant depending on the flux. The rotatory magnetic field is obtained by two two-phase currents through two windings on the stator of the exciter, or three windings and three three-phase currents may be employed.

* Previous articles appeared in *The Electrician* of July 20 and 27, August 3, 24, and 31, and September 14 and 28.

Digitized by Google

Fig. 50 show the general arrangement of the machine. The co-efficient k may be given a number of values, whole numbers or fractions; $k=1$ and $k=-2$ are the most useful. When $k=1$ (Fig. 48) the machine can be excited with single-phase alternating current. The alternating magnetic field is then to be considered as the superposition of two rotatory fields rotating in opposite directions at a speed ω. One of these, rotating as it does at the same speed as the armature, generates no current in it, and the system works as if it had one field rotating at the speed $-\omega$.

When k is given the value -2, the exciter can have half as many poles as the alternator, and yet only two brushes per pair of poles. Fig. 49 shows the connections for the armature of this arrangement, and it is the system adopted in the machine at the exhibition. The exciter is directly coupled to the shaft of the alternator, turning at 250 revs. per min., and has therefore been given 12 poles.

Another extraordinary feature of this set is that the field magnets of the alternator are provided with two windings which can be excited with two-phase current by slightly modifying the exciter. The design is intended to give the remarkable result that the machine shall be asynchronous—that is to say, that the frequency of the alternator is not necessarily exactly proportional to the speed of the field-magnets. It would seem, however, that this *tour de force* has a disadvantage which counterbalances any advantages that it might have for parallel running. Although the machine may be asynchronous, when the slip is only very slight an enormous difference in the output ensues; for instance, it appears that the load can vary from zero to a maximum for a slip of less than 1 per cent. As all true inventors, M. Boucherot has invented a further device to overcome the defects of the first invention. This device is for the purpose of counteracting the above effect and

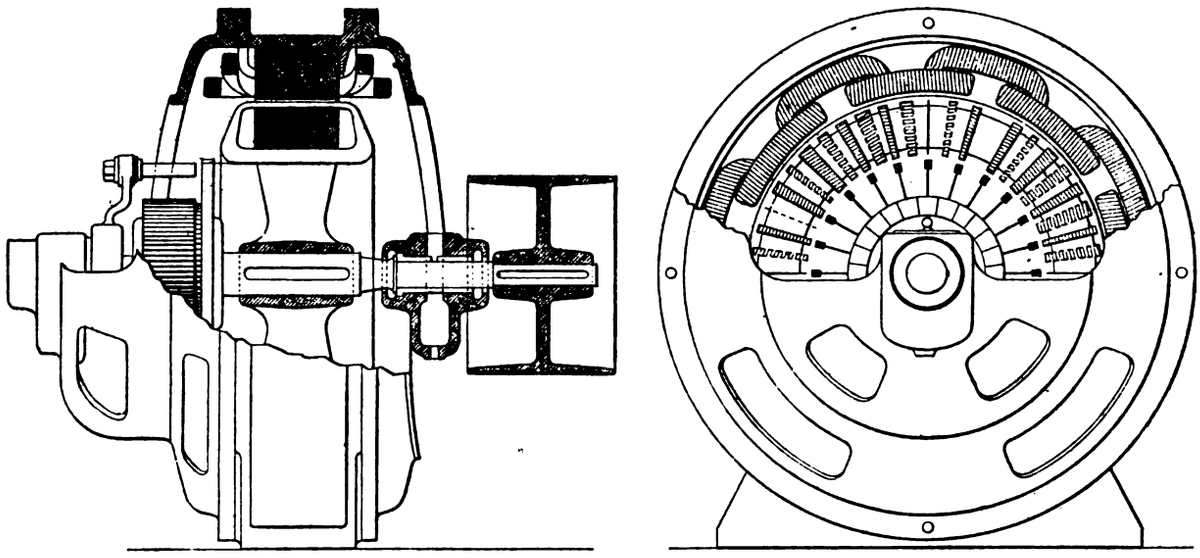

Fig. 50.—General Arrangement of Boucherot Exciter.

Thus the exciter, when it is itself excited with a three-phase current, delivers continuous current from its terminals; but the connections to produce compounding of the alternator, so that its terminal potential difference is constant whatever the current, have still to be explained. These connections are very simply made by means of the three-phase transformer already alluded to, and are shown in Fig. 51. The primaries of

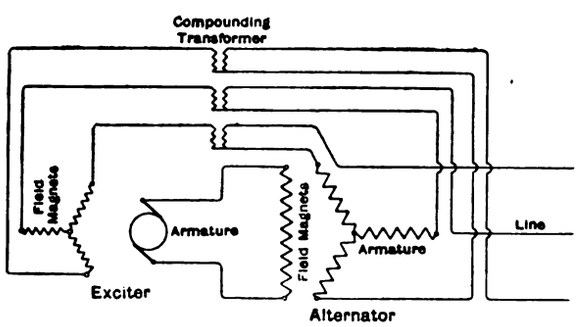

Fig. 51.—Connections of Boucherot Exciter and Alternator.

this transformer are in the main circuit of the alternator, and thus the E.M.F. of the secondaries will increase as the current supplied to the main circuit increases. The secondaries are consequently connected in the circuit between the armature of the alternator and the field coils of the exciter, so that the greater the current supplied by the alternator the greater is the excitation of the exciter. This increases the E.M.F. generated by the armature of the exciter as the load increases, which in its turn increases the current through the field winding of the alternator and reinforces the alternator E.M.F.

rendering the machine "panchrone," as M. Boucherot terms it, a word intended neither to suggest perpetual motion nor finality of design for all time, but merely to indicate that the power supplied is practically independent of the speed. However, as the machine is excited with continuous current at the exhibition, I will not enter into the "asynchronous-panchrone" theory here. Those readers who desire to study it may refer to an article by M. Boucherot himself in the *Industrie Electrique* of July 25. It should be added that by the end of June the compounding exciter had not yet put in an appearance at the exhibition, and the alternator was being excited by an ordinary continuous-current dynamo. The alternator is driven by an enclosed Delaunay-Belleville vertical triple-expansion engine. This engine has two low-pressure cylinders, placed below the H.P. and I.P. cylinders respectively, and the two cranks are set at 90deg. Its main dimensions are:—

Diameter of H.P. cylinder	510mm.
Ditto I.P. do.	820mm.
Ditto each L.P. do.	850mm.
Stroke	460mm.
Length of engine overall	2·850 metres.
Width ditto	2·400 do.
Height ditto	5·250 do.

An alternator exhibited by the Compagnie Générale Electrique of Nancy resembles very much the Schuckert machine described in a former article. In Fig. 52 it is seen that it follows the same lines in several respects, including the radial stays for stiffening the armature. In the background on the left is seen a large but ugly three-phase alternator made at the French works of the Electricité et Hydraulique Co. It develops 210 amperes at 2,200 volts per phase, with a frequency of 50 $\sim$ per sec. and 94 revs. per min., and its ungainly appearance seems due to the small proportion

Digitized by Google

between the width and diameter of the armature. In the background on the right of Fig. 52 a glimpse is caught of the Décauville machine described in *The Electrician* of August 24 (p. 666).

The Nancy alternator has an output of 450 kilovolt-amperes at 3,000 volts and 50 ∽ per sec., when making 93·5 revs. per min. Its armature is built up of core discs ½mm. thick, insulated from one another by paper. These are held in place by four semi-circular castings with ventilation holes, this frame being stiffened, as already mentioned, by radial wrought iron rods. The winding is placed in micanite tubes. The internal diameter of the armature is 4½ metres, and its external diameter 5·050 metres. Its width is 580mm. and it has 96 coils wound in 384 holes, 32 coils in series constituting the winding of each phase. The total weight of the armature is 14 tons. Cast-steel is employed for the flywheel field magnet, which has 64 poles of elliptical section and weighs 9·6 tons. The cables connecting the field coils to the slip rings are led through one of the arms of the flywheel. A series-wound exciter is employed, generating 75 amperes at 120 volts. The alternator is driven by a single-cylinder Weyher and Richemond engine.

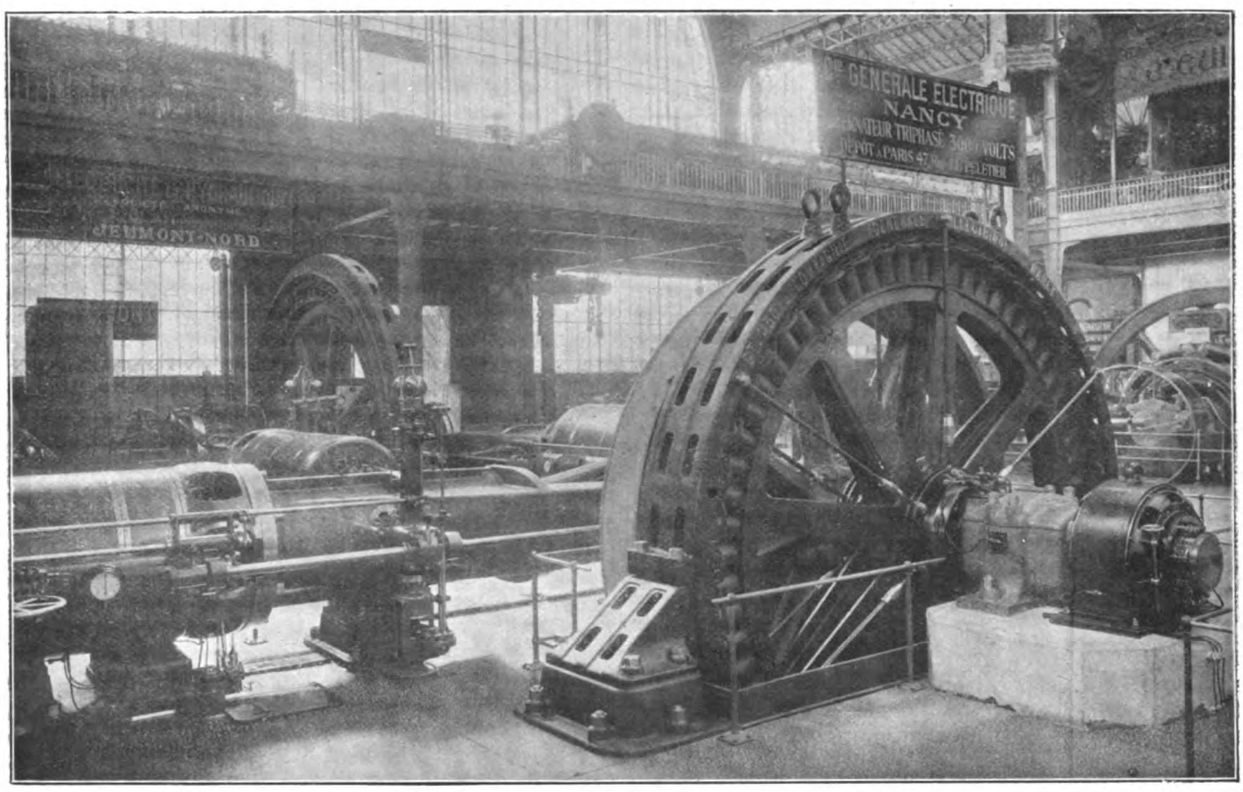

FIG. 52.—ALTERNATOR BY THE COMPAGNIE GÉNÉRALE ELECTRIQUE OF NANCY. 450 kilovolt-amperes at 3,000 volts.

Another French alternator of good, normal design without startling peculiarities is the Labour machine, driven by a tandem compound Dujardin engine, with Corliss valve gear. Messrs. Dujardin & Co., it may be mentioned in passing, exhibit a number of engines of various types, typical of the best French practice of to-day. The alternator is three phase, and intended for an output of 1,200 apparent kilowatts on a load factor of 0·5 at 3,000 volts and 50 ∿ per sec. The flywheel field magnet has a diameter of 5·6 metres, and revolves at 80 revs. per min., requiring about 100 amperes exciting current at 220 volts, when the alternator is fully loaded. A feature of the machine is the bronze ⌊⌋-shaped connectors between the coils of the armature.

The Société de l'Eclairage Electrique, who are the makers of the Labour dynamo, have in their general exhibit a 30,000-volt single-phase alternator, which is, however, not shown in operation. A ring-shaped casting is bolted to the bed-plate, and the annular core of the armature is concentric with this, being held at about 3in. distance by brackets. The armature is fixed, and a 14-pole field magnet revolves within it. The windings are laid four together in micanite tubes in tunnels in the armature, but there are twice as many holes as necessary for the winding, so that every alternate hole only contains windings. The field magnets turn at 428 revs. per min., and the frequency is 50 ∼ per sec.

A fine 800 apparent kilowatt three-phase set, exhibited by the Fives-Lille Company is of the usual flywheel type, and is driven by a cross-compound horizontal Corliss engine, the dynamo being placed between the two cylinders, Another large set is a 1,000kw. three-phase Thomson-Houston alternator built in France for the French Thomson-Houston Co., and driven by a vertical cross-compound Allis engine, likewise constructed in France by the Société Française de Constructions Mécaniques (Anciens Etablissements Cail). The alternator follows the usual Thomson-Houston design. It is 40-polar, and generates current at 5,500 volts and 25∽ per sec. The dynamo is placed next to a flywheel between the cylinders of the engine.

Shifting the Blame.—There seems no end to the mischief wrought by stray electric currents in the ground. The asphalt pavements in Brooklyn, it is said, are being ruined by leaking gas mains beneath them. The hydro-carbons used in enriching the gas are excellent solvents of asphalt, and so soften it in spots that it breaks up and crumbles. The gas companies, when brought to task for the injury done by their mains, however, shift the blame to the electric railway companies, whose wandering return currents they assert cause corrosion of the gas mains and consequently give rise to the gas leakage which, in turn, develops the trouble with the pavement.

THE INTERNATIONAL ELECTRICITY CONGRESS.

(*Concluded from page 844.*)

Section III.—*Electrochemistry.*

M. Keller's Paper, an abstract of which appeared in our last issue, was read on Tuesday, August 21st. In the discussion on it Mr. Petavel asked what would be the best disposition for the alternators in the furnaces. M. Keller replied that the alternators might be about 2m. from the furnaces with a separation wall between them. Thus the cables would be from 18m. to 20m. long and the power factor as high as 0·9. Some existing installations had a power factor as low as 0·7. M. Keller estimated an expenditure of from 50f. to 60f. of electrodes per ton of carbide, based on the price of 60f. per 100kg. of electrodes. With perfected furnaces, 25f. worth of electrodes per ton of carbide could be arrived at.

M. Hollard then read a Paper on "The Principles of Electrolytic Analysis." In electrolytic analysis, he said, the separation of metals based on the polarisation E.M.F.s of their salts had been insisted upon too much. This principle was not true in analysis where the polarisation E.M.F. depended on the concentration of the metal and where the concentration diminished at every instant as metal was gradually being deposited. The principle could, however, be applied when the E.M.F.s of polarisation were large enough not to be neutralised by the diminution of the concentration of the bath. Hence a first classification of the metals into groups. These groups could again be sub-divided according as the ions of the metals in them were incapable of electrolytic deposition or if the complex ion was partly dissociated. M. Hollard then spoke of the influence of the current and current density on analysis and described a new system of electrodes.

On Wednesday M. Zenger described a battery which would utilise sea water for the production of electrical energy. One electrode was a porous carbon tube filled with bromine and the other an iron tube pierced with holes and filled with pieces of iron. The whole was immersed in a solution of bromides and alkaline chlorides which were residues from the manufacture of marine salt. These salts would be so hygrometric that it would never be necessary to replace the water. The bromine tube was hermetically sealed and did not give off gases. This battery had given very good results for telephony, telegraphy, with or without wires, and optical telegraphy. The weight of the cells was about one-third that of the corresponding Bunsen cells or accumulators. The author proposed to utilise these batteries for the production of electrical energy, and thought that bromine might sink to a very low price; iron had little value, and the alkaline salts were residues of manufacture. General Sébert, the chairman, said that the principle of this cell had been indicated by Col. Renard. M. Vignon remarked that bromine was worth 2fr. 50c. per kg., and its production was so limited that its commercial utilisation in M. Zenger's battery seemed difficult.

Section IV.—*Telegraphy and Telephony.*

The first Paper read in this section was by M. André, on a central battery telephone system. This was followed by a communication from Dr. Rudolph Blochmann on the question of the directibility of apparatus for telegraphy with electric waves. The author's hypothesis was that the terrestrial globe was surrounded by equipotential surfaces which are not troubled by an object raised in the atmosphere provided that it has no great sectional area as, for instance, a high vertical metallic wire. But if electrical oscillations were produced along this wire the equilibrium of the equipotential surfaces would be disturbed in the same way as the surface of water is disturbed when a stone is dropped into it. Just in the same way waves were produced which extended from place to place, and which could be received by the vertical wire attached to the receiving apparatus. If this hypothesis were a true one, Dr. Blochmann pointed out that the directibility of the apparatus now employed for the new telegraphy must be regarded as impossible. Capt. Ferrié asked how Dr. Blochmann explained that transmission was better between two stations separated by water than between two inland stations, and Dr. Blockmann replied that the equipotential surfaces were much more regularly distributed on the water.

On Tuesday Prof. Châtelain read a Paper by M. Popoff on telephonic receivers for wireless telegraphy. M. Popoff suggested that the diminution of resistance in the radio-conductor or coherer could be directly observed by a telephone. In July, 1899, he had utilised this phenomenon in an apparatus constructed for him by M. Ducretet. The receiver included a cell in circuit with a telephone and a "radio-conductor" of steel filings whose surface was oxidised. Experiments made in the winter in the Gulf of Finland with stations 47km. apart were quite successful. The masts were 48 metres high, and one of them was in a forest 5km. from the sea.

M. Willot followed with a note on wireless telegraphy, in which, contrary to the results obtained by Mr. Marconi at the naval manœuvres last year, he expressed the opinion that it was necessary for the transmitting and receiving stations in a wireless telegraph system to be in sight of one another, as the curvature of the earth's surface presented an insurmountable obstacle. He then suggested a new system of wireless telegraphy by employing different strata indicated in the geological maps, and connecting the two stations by means of this strata. We referred to this suggestion in an editorial note in our issue of Sept. 21. M. Tissot favoured the equipotential surface theory of Dr. Blochmann. He had transmitted messages successfully between French warships in the Channel, 89 nautical miles apart, and with masthead wires 26 metres long. Contrary to M. Popoff he was particularly careful to exclude any oxidised filings in the construction of his coherers.

Mr. Gavey then described what had recently been done in this country in connection with wireless telegraphy. In February, 1894, he was engaged in experiments with the electromagnetic system of wireless telegraphy across Loch Ness, the object in view being the discovery of the law which governed this method of transmission. It occurred to him to endeavour to establish communication by means of telephones, and this was done with thoroughly satisfactory results, conversation being readily exchanged between two parallel wires separated by a distance of 1¼ miles, the wires themselves being 4 miles in length. The question had been allowed to rest for some time, but recently it had become necessary to establish communication between the rocky islets known as the Skerries and the Coast Guard station at Cemlyn, in the Island of Anglesey. Accordingly a wire 750 yards in length was erected along the island, and a corresponding wire, roughly parallel with it, was erected from a point opposite the Skerries to Cemlyn Station, a distance of 8½ miles. The average distance between the two wires was 2·8 miles. Telephonic communication had been thoroughly practicable, and is now in daily use. Further experiments, between the north coast of Ireland and Rathlin Island had recently been made, and it was found in this case that a similar system could be worked at an approximate distance of 6½ miles between the transmitting wires.

M. Chaye-Pacha then spoke of an application of the microphone for the security of fishermen in Newfoundland to enable them to hear the approach of a steamer. The apparatus consists of a microphone enclosed in a box and immersed in the water. It is connected to a battery and a telephone on the boat. The noise of a steamer can thus be heard 4km. or 5km. away. By covering the microphone box almost entirely by means of a sound proof cover, such as a double wall of lead enclosing lampblack, and by providing the uncovered part with an acoustical trumpet, the direction the sounds come from can be determined. M. Roosen read a Paper reviewing the different systems for underground telephone cables, and expressed himself in favour of the system of stoneware pipes employed at Brussels. A discussion on the various systems followed, in which MM. Wunschendorff, Gavey, West and de la Touanne took part.

On Wednesday the proceedings were opened with a Paper by M. Blondel and Capt. Ferrié on "The Present Condition, and Progress Made in Wireless Telegraphy by Hertzian

Digitized by Google

Waves." We shall publish an abstract of this Paper. This was followed by a communication by M. Pinter on the Pollak-Virág system of fast speed telegraphy, a sysrem which has been fully described and discussed in our columns. The third Paper was by M. O. Rochefort on "Unipolar Transformers." It gave data of the construction of induction coils made by the author and employed by M. Tissot in wireless telegraphy. The primary is not essentially different from that of the classical Rhumkorff coil, but the secondary is formed of a single flat coil covering the central half of the primary, or two such coils in series. Dr. Blochmann announced that he had asked M. Branly's permission to propose that the Congress should pass a resolution to call the filings tube the Branly tube, but this gentleman had declined the honour in a letter which Dr. Blochmann read to the meeting.

On Thursday the first Paper was communicated by Capt. Squier and Mr. E. Crehore and presented by Dr. Kennelly on "A Practical Telegraph Transmitter Using the Sine-Wave for Operating the Wheatstone Receiver." An abstract of this Paper has already appeared in our columns. Dr. Kennelly referred to the experiments which had been made in England between London and Edinburgh, and said that the system had recently been employed in America on a line belonging to the Commercial Cable Co. between New York and Canso, a length of about 2,000km. Mr. Gavey spoke of the great improvements that had recently been made in the Wheatstone system, enabling up to 400 words per minute to be transmitted with batteries, and said that Capt. Squier's experiments had been made on a Sunday on a quiet line which was not subject to inductive disturbance from neighbouring circuits. The subject of sine-wave transmission on submarine cables is referred to in our leading article this week.

Capt. Ferrié described numerous experiments he had made with carbon-carbon, carbon-metal, and metal-liquid coherers. He had found that a carbon-metal contact was more sensitive than a carbon-carbon contact, and a metal-liquid contact was less sensitive. He also put forward a theory of the action of the coherer.

M. Semenov followed with an account of some experiments which he had made with an adjustable coherer to determine whether it was a coherer or a "radio-conductor," and expressed himself in favour of the cohesion theory.

M. Bodde described an apparatus designed to utilise wireless telegraphy for the avoidance of collisions at sea. The transmitter is put in the focus of a parabolic cylindrical mirror, which is turned round its focus so as to send Hertzian waves successively in all directions. These waves are received by the receiving masts of neighbouring vessels in the ordinary manner. Each vessel is provided with a similar transmitting and receiving apparatus, and to prevent the two from affecting one another the author suggests a commutator tuned in synchronism with the transmitter mirror. He had not been able to make experiments on a large scale, but had verified the fact that when using the commutator the desired effect of screening the receiver from the transmitter on the same vessel had been attained.

Section V.—*Electro-Physiology.*

M. Bergouie, who occupied the chair on Monday in the absence of the President of the Section (M. D'Arsonval), observed that as the Congress had been preceded by congresses on radiology, radiography and medicine, the number of interesting communications and reports was limited.

M. Stanoiĕvitch read an interesting Paper on the analogy between the lines of magnetic and electromagnetic force in machines with the disposition of cells in plants. He described a series of investigations which had extended over four years, and which had led him to conclude that the organic cells obeyed the laws of Maxwell, and that they acted proportionately to the product of their mass and in inverse propertion to the square of their distance apart. Other Papers were read, but they were of medical rather than electrical interest.

At the meeting of the official delegates of the various governments, the recommendation of Section I. that the names "gauss" and "maxwell" be given to the C.G.S. units of magnetic field and magnetic flux respectively, was adopted by a majority of the delegates, as also was a resolution proposed by M. Stanoiĕvitch that electrical energy should be protected by law in the same way as any other property.

At a general meeting of the delegates on Saturday, August 25th, besides a number of speeches of congratulation and thanks from the French and foreign members, a resolution, put forward by sub-section B of Section II., was passed, requesting the governments to facilitate as much as possible the establishment of overhead and underground circuits intended for transport and for the distribution of electrical energy.

ELECTRICITY WORKS ACCOUNTS.

Blackpool Municipal Electric Supply Works and Tramways.

The figures we give this week in our analysis of the accounts of the Blackpool undertaking indicate most satisfactory working during the year 1899-1900. In consequence of the reduction of the initial price in the tariff from 8d. to 7d., the average revenue from all sources has dropped from 4·29d. to 3·86d. per unit sold. Thanks to the lower costs of working, however, this reduced revenue has not had such an influence as might have been expected on the working profit, which was £7,963, or 7·22 per cent. of the mean capital, as compared with £7,450, representing 8 per cent. on the capital, in the preceding year.

Comparing the business done in the two years, it will be found that while the lamp connections increased 29·6 per cent. the output advanced by 32 per cent. In 1898-9, of the total output of 870,184 units sold the tramways took 181,850 units, or 20·9 per cent., and the public lamps 164,922 units, or nearly 19 per cent. Last year, of the total output of 1,148,564 units sold 228,651 units, or 19·9 per cent., represented the supply to the tramways, and 193,053 units, or 16·8 per cent., the amount used in public lighting. It is somewhat surprising to find that, with the above proportions of arc lighting and traction loads, the load-factor should be barely up to the average of municipal stations in 1898-9. The value of this factor in Blackpool in 1898-9 was 10·46 per cent. Last year it was 10·1 per cent.

Among the generating costs the items of fuel and repairs and maintenance have risen—the former very considerably—viz., from 0·55d. to 0·70d. per unit. Even at the present figure, however, this charge is well within the average. The items of oil waste, water, &c., and repairs and maintenance, are above the average. Although the collective generating and works costs have increased, they still, together with the total costs, present excellent figures.

In our second table is given a summary of the tramway accounts for the two years ended at March 31, 1900. It will be seen that while the working expenses both at the station and on the route had increased slightly, the management, property, and general charges were diminished sufficiently to do more than neutralise the increase in the working costs.

During the year ended at March 31 last there was special expenditure on account of doubling the line from Church-street to Springfield-road and from Hounds Hill to Church-street. This expenditure was £4,210, and of it a third, or £1,403, was charged to revenue, the remaining two-thirds being carried forward in suspense. In our analysis this charge of £1,403 has been deducted out of the working profit merely, and therefore does not enter into the revenue account to vitiate a fair comparison of the two years' results. A loss of £809 on realisation of the centre-channel stock plant has not been charged to the repairs and maintenance out of revenue, but to the net revenue account with the reserve fund contribution. Last year the traffic on the tramways was 3,421,736 passengers as compared with 2,881,027 in 1898-9—an increase of 22·7 per cent. The figures for the car mileage were respectively 318,885 and 259,754—an advance of 18·75 per cent.

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny

Editorial Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"The Electrician" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	

New Volumes of "The Electrician" *commence in April and October.*

"The Electrician" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 9d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. R. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints" on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By H. Trehlett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d., post free 13s. Vol. II. Price 12s. 6d.; post free, 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. New Edition. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. New Edition. 93 original illustrations, price 6s.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. New edition. Price 10s. 6d., post free; abroad 11s.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d. post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d.; post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gempel and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free 2s. 2d. each; strong cloth 2s. 6d., post free 2s. 8d. each. Single Primers 2d., post free 2½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O. J. Lodge. New Edition. Price 5s. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, ELECTRIC TRACTION, TELEGRAPHS, TELEPHONES, &c. A. C. Curtis-Hayward, B.A. To January, 1900. Price 3s. 6d., post free.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work is in the press and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. Raphael. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

THE TELEPHONE.—By Dahl Sinclair and F. C. Raphael.

SPECIAL NOTICES.

NOW READY.—Vol. XLIV. of "The Electrician" (950 pages) bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of "The Electrician" (1878-1900) can now be supplied. These sets are very scarce, and early application should be made

SINE-WAVE TRANSMISSION ON SUBMARINE CABLES.

Messrs. Crehore and Squier's system of sine-wave transmission of signals through submarine telegraph cables has been before the telegraphic world for some time past. A Paper on the subject was presented by these inventors to the American Institute of Electrical Engineers, at Philadelphia, last May, when it met with considerable discussion. The subject was again brought forward at Paris during the International Congress of Telegraphy. An abstract of the Paper, which was then read for the authors by Dr. A. E. Kennelly, appeared in our issue of September 7th. The authors have advanced this important subject in two directions. In the first place they have drawn attention to the circumstance that the sine-wave form of transmission of currents is one (though possibly not the only one) which can be utilised to convey the necessary energy through cables without undue waste of time or power, and in the second place they have devised a simple apparatus whereby as close an approximation to the sine-wave form as the shape or composition of the cable signals will admit of is given to the impulses required for their production. Their formulæ for calculating the impedance of the various parts of the circuit may also prove of service, and should result in improvements being made in the proper proportioning of the apparatus to the cables they are meant to work. There is undoubtedly room for progress in this direction, particularly in connection with the arrangements at the receiving end of the line. By this is meant that it is highly probable the best definition of signals will be obtained, other things being equal, when the receiving condensers, resistances, and instruments in circuit are correctly tuned to the frequency of the arriving waves, and the formulæ may assist towards this by enabling us to calculate what the impedance at the receiving end should be to satisfy the conditions under which the waves are being propagated. It has been recognised for some time past that the only true method of comparing the relative speeds of cables differing either in design or length, lies in the comparison of the frequencies at which impressed sine-waves produce records of standard amplitudes at the distant ends of the cables; but for these comparisons to be just, it is necessary to employ a recording instrument having no appreciable electro-magnetic or mechanical inertia,

Digitized by Google

so that of itself it does not influence the results. An oscillograph of sufficient sensibility would, in other words, be required for such tests, and were one available, many interesting and really pressing questions connected with the design and working of submarine cables might at once be answered.

The alternate-current measurements made by Messrs. Crehore and Squier take the form indicated, in every respect, with the exception of the receiving instrument, which appears to have been an ordinary siphon recorder, similar to those usually employed for signalling on submarine cables, aud the adjustment of which remained unaltered throughout the experiments. There is a disposition, therefore, to regard the results they obtained rather as measurements of the sensibility of the instrument to the amplitude and frequency of the impressed waves than of the speed capacities of the cables in question. In other words, the dying-away of discernible signals at the frequency of about seven complete waves per second, whatever the voltage employed, is attributed more to the want of synchronism between the coil of the receiving apparatus and the frequencies than to the reduction of the amplitudes occasioned by loss of energy along the cable. Judging from the remarks made by several of the speakers at the discussion in Philadelphia there seems to be an impression, in America at all events, that little or nothing has been done for many years to improve the carrying capacity of cables. This impression, however, is not correct. The problem of employing the materials of which cables are constructed to the best advantage has been forced upon cable engineers, not only by the enhanced cost of these materials, but also by the enormous increase generally of the traffic which cables nowadays have to carry. A large amount of patient experiment has been undertaken from time to time in every direction promising an advancement upon old practice, and, as a consequence, a good deal has been quietly accomplished by modifications, not only in the construction of the cores of the cables themselves, but notably in the methods and apparatus by which they are worked. Amongst other things, nearly every conclusion come to by Messrs. Crehore and Squier, as the result of their investigations and experiments, has been anticipated on this side of the water. The improvement in the received signals as the result of modifying the impressed wave-form and increasing the E.M.F.—the difference between the virtual voltage and that impressed upon the near end of the line—the possibility, in consequence, of being able to raise the virtual voltage to the highest useful limit without endangering the cable, and the influence of the composition of the signals upon the speed at which they can be transmitted, are all facts which have been ascertained, recognised, and acted upon.

But the methods of experimenting which have led to the discovery of these facts, and the means by which the impressed wave-form is modified to produce the best results at the further end of the cable, are entirely different to those employed by the designers of the sine-wave transmitter. It has been ascertained that, by adding a certain resistance to the battery circuit (a condenser at the sending end being used), and at the same time raising the voltage—to compensate for the reduction of effective pressure which the addition of the resistance would otherwise cause—a remarkable increase in the amplitude of the received signals is produced. This result seems capable of explanation in the following manner: The effect of the inserted resistance is to retard the rise of potential in the condenser, and to cause the current flow to extend over a longer portion of the total period of the battery contact, and, since the maximum height of the pressure curve is at the same time maintained by proportionately increasing the E.M.F., the total energy imparted to the cable is appreciably increased, and the amplitude of the signals at the further end is consequently enlarged.

The combined effect of the condenser and resistance is, in fact, to cause the front at least of the impressed wave to assume an approximately sine-wave form. Between the signals the condenser is not earthed through the resistance, but directly. It might be anticipated that this would destroy all further semblance to the sine-wave, but there is a certain amount of evidence that this is not the case, although unfortunately it is not yet conclusive. There is an inclination to believe, however, that, for some reason, harmonics do not exist during the discharge, in spite of the sudden earthing; or that if they do they are in some way beneficial, since the definition of the signals does not appear to suffer, but is, on the contrary, rather improved, and in any case is markedly better, allowing for differences of K.R, than that produced at Canso by the alternator transmitter on the Coney Islahd cable. As, however, the rather disappointing character of the latter signals may be due to a number of complicated causes foreign to the transmitter, the question of the relative superiority of the two systems must be left to be decided by the results of further and more exact investigation. It is to be noted, however, as a significant fact, that Messrs. Crehore and Squier do not specifically claim to have obtained higher speeds, or better signals, on either of the cables experimented upon with their transmitter; and, further, it would appear that their signals were identical in shape and size with others produced by the ordinary methods at the same speeds. It is just possible, therefore, considering the complexity of the phenomena attending the transmission of electric waves through submarine cables, and that two important factors at least—the inductance and the dielectric conductivity—have not been accorded whatever weight may be due to them, that the sine-wave theory may eventually be found not to fit the problem so completely as has been supposed, and that the tuned condenser method, if so it can be designated, may prove by its flexibility to admit of a closer adjustment of the conditions at the sending end to the requirements of the cables and receiving apparatus. It would not be advisable, therefore, for these and other reasons—among which is the question of expense—to advocate the immediate abandonment of present methods for one which, though it certainly has theory to commend it, has not as yet given incontestible proof of its superiority in practice. Two of the chief recommendations of the alternator transmitter are, it would seem, freedom from delicate mechanism and from sparking; and it also undoubtedly brings us one step nearer to the possession of signalling apparatus designed upon engineering rather than on watchmaking lines. This last is a matter for congratulation.

REVIEWS.

(Copies of any of the undermentioned works can be had from *The Electrician* office, post free, on receipt of published price.)

The Law and Practice relating to Letters Patent for Inventions. By Roger William Wallace, Q.C., and John Bruce Williamson. (William Clowes & Sons, London.) 40s.

Two colossal works on patent law having been reviewed in our columns within the last three years, it may seem surprising that there has been found room for another one. The newcomer is even more colossal, though not unreasonably so, having regard to the ever-increasing pile of judicial decisions which must needs be noticed. In printing and general

Digitized by Google

appearance it will compare favourably with any of its predecessors, or, indeed, with most legal volumes with which we are acquainted; and it is decorated on the cover, by official leave, with an impression of the Patent Office seal bearing the Royal Arms. In arrangement of the subject, the authors have not departed materially from that of previous writers, which is one necessarily involving a vast amount of repetition, though this is not, we think, quite so apparent in the present work as in some others. In the usual table of cases at the beginning a small but welcome addition is made by giving the subject of the patent dealt with. Many people who would not recollect the purport of the decision, say, in the case of Savory *v.* Price, would recognise it at once under the title of the "Seidlitz Powder case." The first chapter gives an interesting summary of the events leading up to the Statute of Monopolies passed in 1624. It is pointed out that this act, although the Magna Charta against oppressive monopolies, did not introduce any new principle, since such monopolies, had always been illegal according to common law. So early as the reign of Edward III., a licence under the great seal purporting to grant a monopoly for the sale of a well-known commodity had been declared void, and the holder of it severely punished by Parliament. The Tudor sovereigns and James I. had granted monopolies more or less in defiance of the law, but even under Elizabeth, the Court of King's Bench had the courage to declare one of these to be utterly void and contrary to law. The statute of James's reign was therefore a declaratory and regulating act rather than a new departure in legislation.

The chief novelty since the last general treatise on patent law appeared, is the practice relating to compulsory licences. Mr. Gordon has so recently and exhaustively dealt with this as a separate subject, that the authors have contented themselves with a comparatively short chapter upon it. We are glad to notice, however, that they endorse the opinion expressed in Mr. Gordon's book, as to the inconvenience of the practice under which the Board of Trade gives judgment based upon the report of a legal referee before whom the case is tried, while the report itself is withheld from publication, so that the reasons for the decision never appear. Since one of the authors has himself, on more than one occasion, acted as referee, this opinion should carry all the more weight, and, we hope, may lead to the conviction that some alteration in this respect is expedient. The appendices, which contain forms and circulars issued by the Patent Office as well as numerous precedents, seem very complete, including a specimen form of specification with drawings.

THE MAGNETIC PROPERTIES OF IRON FILINGS AS AFFECTED BY FERRO-MANGANESE.

BY PROF. ERNEST WILSON.

It has long been known that manganese steel containing a sufficient quantity of manganese is practically a non-magnetic substance. The author thought it would be of interest to examine the magnetic properties of a mechanical mixture of iron filings and ferro-manganese; to compare these with the magnetic properties of simple iron filings; and to examine the effect produced upon the magnetic properties of the two mixtures by raising their temperatures to 800°C. or 900°C.

The method of experiment was to place the filings in an asbestos box having the shape of a hollow cylinder. On this cylinder were wound primary and secondary coils consisting of asbestos-covered copper wires, the secondary next the cylinder. The cylinder was then enclosed in an iron box and the whole placed in a Fletcher furnace ready for heating. The magnetic properties of the mixtures could be then examined by aid of a ballistic galvanometer, before and after heating, without disturbing the specimen. The temperature was calculated from the increase in electrical resistance of the secondary coil. Finally, in order to eliminate the correction due to the asbestos of the box and wire covering (which was taken to be non-magnetic) the filings, which had become solid after heating, were stripped of the asbestos and re-wound with new primary and secondary coils of cotton-covered copper wire. Experiments were again made with the ballistic galvanometer at atmospheric temperature. In the first case the area of asbestos between secondary and filings was 50 per cent. of the actual area of the filings. In the second case the area of cotton between secondary and filings was 5 per cent. of the area of the filings.

The iron filings were made with a new 12in. rough file from a bar of Turton's Bessemer steel, containing approxi-

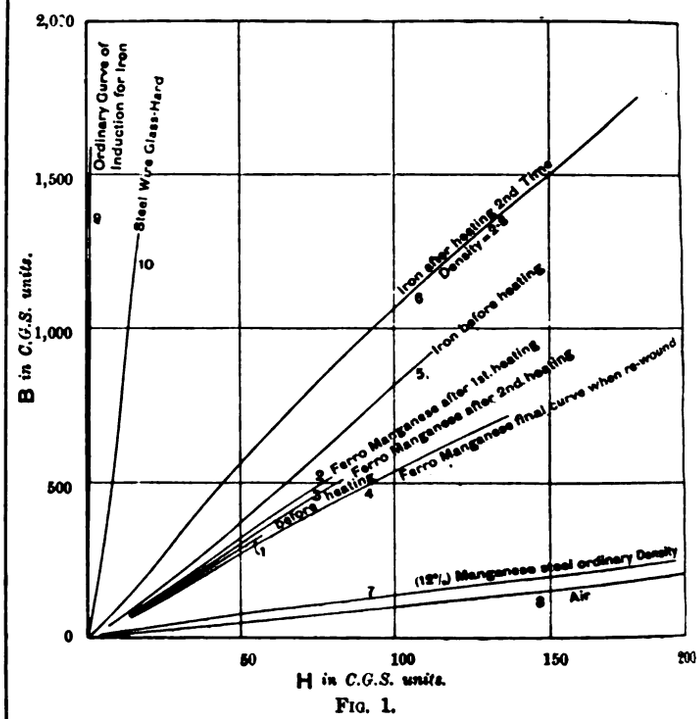

FIG. 1.

mately 98·5 per cent. iron, 0·8 per cent. manganese, 0·45 per cent. carbon, 0·12 per cent. silicon, with traces of sulphur and phosphorous. The ferro-manganese was in form of powder, containing about 85 per cent. manganese, 8 per cent. iron, 6 per cent. carbon, 1 per cent. silicon. The mixture of iron filings and ferro-manganese used contained 17·8 per cent. by weight of ferro-manganese. The dimensions of the asbestos boxes used were: Internal diameter 2·5cm., external diameter 4·8cm., length 2·8cm.

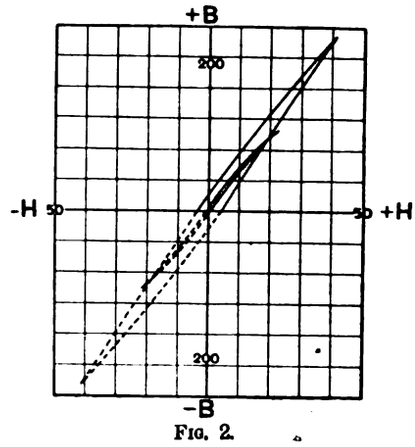

FIG. 2.

The density in grammes per cubic centimetre of the iron filings and ferro-manganese after heating was 2·81, being an increase of about 7 per cent. on its original value. The density of the iron filings only after heating was 2·8, being an increase of about 3 per cent. on the original density.

Fig. 1 gives the relation between B, the induction per square centimetre of the cross-section of the specimen, and H the magnetising force per centimetre linear: both in C.G.S. units. Curve 1 was obtained from the mixture of ferro-

Digitized by Google

manganese and iron filings before heating. Curve 2 was obtained from the same specimen after being heated to 667°C., when again at atmospheric temperature. Curve 3 was obtained after a second heating to 860°C., when again at atmospheric temperature. At this stage the cylinder was stripped of abestos and re-wound. The curve 4 was then obtained and should agree with curve 3 if the asbestos were non-magnetic, which was assumed in making the correction,

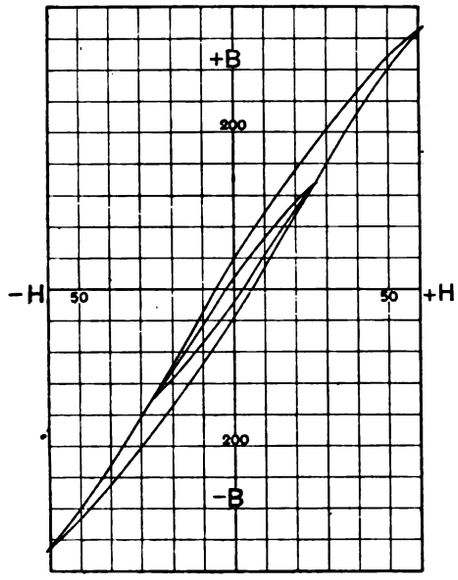

FIG. 3.—Fe and Mn after second heating.

and the true cross-sectional area of the asbestos were known. The first heating increased and the second heating diminished the permeability; the final permeability is slightly in excess of the initial permeability. Curve 5 was obtained from simple iron filings before heating. Curve 6 was obtained after the iron filings had been heated twice to about 900°C., when

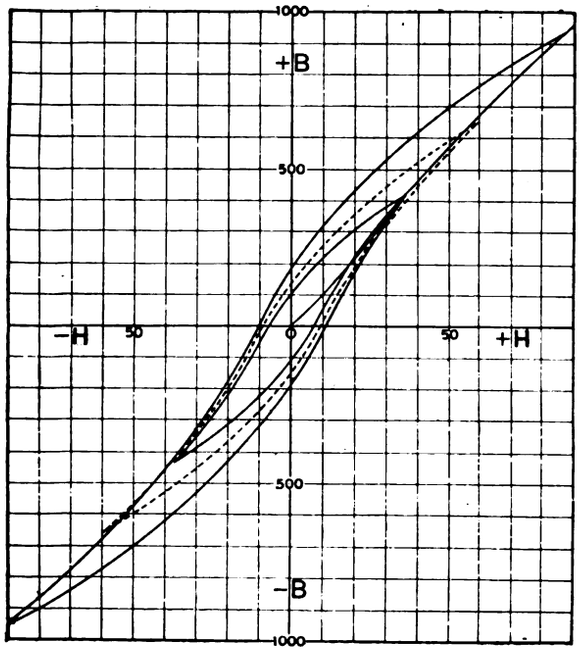

FIG. 4.

again at atmospheric temperature. The simple iron filings have a higher permeability than the mixture of iron filings and ferro-manganese. Moreover, after a second heating the increase in permeability is considerable in the iron filings. It appears that the presence of the ferro-manganese has counteracted the increase in permeability which would have been experienced had the ferro-manganese been absent. These effects may be connected with the formation of iron oxide as a matrix, which is well known to be magnetic, and possible variation in the hardness of the iron filings. In Fig. 1 curve 7 was obtained from a specimen of manganese steel with 12 per cent. manganese.* Curve 8 is the straight line for unit permeability. Curve 9 is an induction curve for ordinary wrought iron, and curve 10 an induction curve for glass hard steel.

We have now to deal with the dissipation of energy by magnetic hysteresis. Fig. 2 shows two curves obtained from the ferro-manganese specimen before being heated. Fig. 3

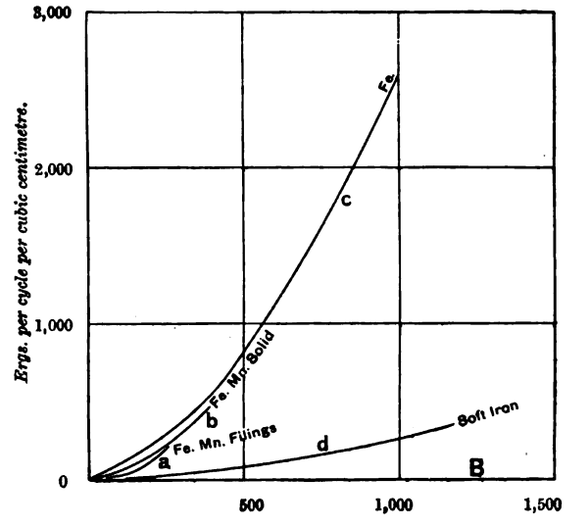

FIG. 5.

shows two curves obtained from the ferro-manganese specimen after the second heating when at atmosphere temperature. Fig. 4 shows three curves obtained from the simple iron filings after the second heating when at atmospheric temperature. In Fig. 5 the dissipation of energy due to magnetic hysteresis obtained from Figs. 2, 3, 4 is plotted in terms of maximum B. In Fig. 6 this dissipation is plotted in terms of maximum H. In Fig. 7 is plotted the coercive force in terms of intensity of magnetisation $\frac{B-H}{4\pi}=I$. In each of the Figs. 5, 6, 7 the curve *a* refers to the ferro-manganese specimen before heating; curve *b* refers to the ferro-

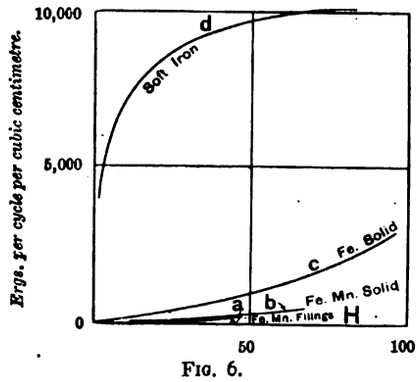

FIG. 6.

manganese specimen after being heated twice; curve *c* refers to the iron-filing ring after the second heating; curve *d* refers to a specimen of good wrought iron. Fig. 5 shows that heating the ferro-manganese specimen has had the effect of increasing the dissipation of energy due to magnetic hysteresis for a given value of B, although in Fig. 1, curve No. 1 indicates smaller permeability than curve No. 3. The simple iron filings after heating dissipate more energy than the ferro-manganese specimen after heating. Each of the specimens

* This specimen had previously been cooled by placing it in liquid air. It is still non-magnetic at atmospheric temperature, but the author cannot say if it was magnetic at the low temperature. It was still non-magnetic at about −80°C. when cooled in carbonic acid snow. The author is indebted to Prof. W. Ramsay, F.R.S., for having cooled the specimen in liquid air.

Digitized by Google

dissipates considerably more energy than a piece of good wrought iron. Turning to Fig. 6, we see that the curves *a*, *b*, *c* have the same relative positions as in Fig. 5, but the soft-iron curve *d* is now much higher than the curves *a*, *b*, *c*. The curves *a*, *b* in Fig. 7 show that the coercive force for these specimens is not nearly constant, as is almost the case with the curve *d* for soft iron,* thereby indicating a much greater possible increase in the dissipation of energy due to magnetic hystersis than has been already observed. The curve *c* more nearly approximates to a constant value of the coercive force, which would probably be several fold that indicated by the curve *d* for soft iron.

Conclusion.—The presence of 17 per cent. by weight of ferro-manganese in a mechanical mixture with iron filings reduces the dissipation of energy due to magnetic hysteresis for given limits in the values of either B or H, after being raised to a temperature of 800°C. to 900°C. The increase in permeability after heating simple iron filings to about 900°C.

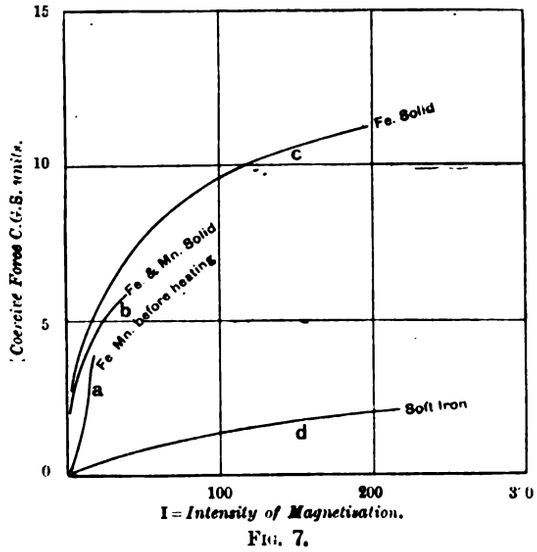

Fig. 7.

is greatly reduced by the presence of the ferro-manganese. Mr. S .L. Walkden has given me assistance in the experimental part of this Paper, and in the working out of the results. I wish to acknowledge this, and to return him my thanks.

THE OSMOTIC PRESSURE THEORY OF PRIMARY CELLS.†

BY W. R. COOPER, B.SC.

(*Concluded from page 854.*)

Measurement of Single E.M.F.s.—The existence of electrolytic solution pressure is purely hypothetical, for unfortunately we have no means of directly measuring it, or of proving that it does exist. Taking it for granted, however, that we have a statement of facts in the equation

$$E = 0{\cdot}0002T \log_{10} \frac{P}{p},$$

it should be possible to deduce the value of the solution pressure in many cases if we could measure single E.M.F.s—*i.e.*, the E.M.F. due to a metal in contact with a liquid.

This E.M.F. must not be confused with the contact force between metals and liquids, which is a purely electrostatic effect, and therefore unable to help us here. The determination of the Peltier effect at such a junction would give a measure of the E.M.F., but the value of such measurements is sometimes disputed. Fortunately, the work of Ostwald, Lippmann, Helmholtz, and others has rendered this possible in another way. One method of arriving at the required result is by means of a dropping mercury electrode. Suppose we have a mass of mercury which is allowed to run into an electrolyte in a fine stream. This stream is continuous near the jet, and may therefore be arranged to form a connection between the electrolyte and the mercury in the reservoir. As the stream falls it breaks into globules. Now, when such a stream starts, the mercury is positively electrified owing to the low value of its solution pressure. But as the flow continues the difference in potential diminishes. In the words of Helmholtz * ". . . . when a quantity of mercury, otherwise insulated, makes contact with an electrolyte by flowing rapidly through an orifice, the mercury and the electrolyte cannot be at different potentials. For if the potentials were different—*e.g.*, if the mercury were positive—each falling drop would present an electrical double layer at its surface, thus removing positive electricity from the mercury, and would gradually reduce the positive potential until it became equal to that of the liquid." Thus the measurement of the single E.M.F. between mercury and a solution becomes comparatively easy. Usually the E.M.F. between two stationary mercury electrodes in the same electrolyte is zero, because the two potential differences involved are equal and opposite. But if one of the potential differences is removed by using a dropping mercury electrode, then the E.M.F. between the moving and the stationary mercury will be simply that between mercury and the solution.

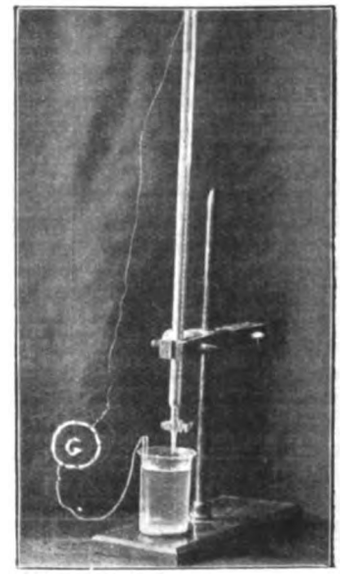

Fig. 3.—Dropping Mercury Electrode.

The mode of action of a dropping mercury electrode may be shown by the simple arrangement given in Fig. 3. A burette serves as the mercury reservoir, and is supported about a centimetre above the surface of dilute sulphuric acid contained in a beaker, which also holds some mercury. Connection is made between the latter and a galvanometer, G, by a wire passing down a piece of glass tubing which is attached to the side of the beaker and dips into the mercury, thus protecting the wire from the acid. A second wire passes from the galvanometer down the bore of the burette, making contact with the mercury which it contains. Upon opening the tap, so that the mercury flows in a rapid stream, a deflection of the galvanometer will be observed.

Another method of measuring single E.M.F.s depends upon surface tension.

As the result of such measurements, it has been found that the E.M.F. between mercury and mercurous chloride in normal potassium chloride solution is 0·56 volt. Knowing this, it is a simple matter to deduce other values on the assumption that the E.M.F. of a cell is the algebraic sum of two such potential differences. For example, if both plates tend to send cathions into solution, they oppose each other, and we have

$$E = E_1 - E_2$$

* This curve is taken from *Phil. Trans.* Roy. Soc., Vol. 184 (1893), A, p. 997.

Digitized by Google

as the resultant E.M.F. Supposing the E.M.F. of the cell, zinc/normal zinc sulphate solution/mercurous chloride in normal potassium chloride solution/mercury, to be 1·08 volts, then, since ions tend to pass *out* of solution in the case of mercury, we have

$$1{\cdot}08 = E_1 + 0{\cdot}56,$$
$$E_1 = 0{\cdot}52,$$

and therefore the value of the E.M.F. between zinc and normal zinc sulphate solution is 0·52 volt.

It should be noted that this value is larger than that resulting from the measurements of the Peltier effect by Bouty.*

Calculation of Electrolytic Solution Pressure.—We now have the means of calculating the values of the various electrolytic solution pressures. We have at a temperature of 15°C. the relation

$$E = \frac{0{\cdot}0575}{n} \log_{10} \frac{P}{p},$$

or

$$\log_{10} P = \frac{nE}{0{\cdot}0575} + \log_{10} p.$$

In the case of zinc, $n = 2$; and if the solution is normal zinc sulphate, $E = 0{\cdot}52$. Also, if we suppose the sulphate to be completely ionised, then the osmotic pressure p due to a gramme molecule in a litre of solution will be 22·38 atmospheres.

Substituting these values, we find $P = 2{\cdot}7 \times 10^{19}$ atmospheres.

The solution pressures of other metals may be calculated in the same way after deducing the values of corresponding single E.M.F.s.

The following examples, mostly due to Neumann, will give an idea of the results obtained, which vary somewhat according to the data on which they are based :—

Magnesium	$1{\cdot}15 \times 10^{43}$	atmospheres.	Lead	$1{\cdot}1 \times 10^{-3}$	atmospheres.
Zinc.....	$2{\cdot}7 \times 10^{19}$	,,	Copper ...	$4{\cdot}8 \times 10^{-20}$	,,
Iron.....	$1{\cdot}2 \times 10^{4}$	,,	Palladium .	$1{\cdot}5 \times 10^{-36}$	,,

These figures will at once strike the reader as somewhat strange, most of them being enormously large or extremely small. It must, however, be remembered that such figures really only represent the striving of the molecules to pass into the ionic state, and the pressures here given are the osmotic pressures which it is necessary that the metallic ions already in solution should exert in order that no ionisation, and consequently no electrification, should take place. It should also be borne in mind that no such pressure has been directly or indirectly observed. All we can say is that if electrolytic solution pressure exists, and if it acts in the way here described, then the magnitude of the pressure must be of the order given above.

From our preliminary discussion of solution pressure, it will be inferred that those metals with the high pressures are negatively electrified, and those with low pressures are positive to solutions of their salts. Between these two extremes metals may be found which are not electrified at all if the concentration of the solution is suitable.

Having found the values of solution pressures, we are now in a position to calculate the E.M.F. of any reversible cell. But such calculations can in no way confirm the values we have already found for the solution pressures, because the latter are based upon the experimental determination of such E.M.F.s. It is simply a case of reasoning round in a circle, and therefore such calculations become of no further interest.

Effect of Varying the Negative Ion.—It will be noticed that the formula arrived at for the value of a single E.M.F. is quite independent of the negative ion: it depends only upon the osmotic pressure of those positive ions which are of the same metal as that which is immersed in the solution, and upon the electrolytic solution pressure of the metal. Thus we should expect the E.M.F. of zinc in zinc sulphate solution to be the same as that of zinc in zinc chloride, provided the degree of ionisation is the same in both cases. This deduction has been verified by Neumann, who carried out measurements upon a large number of salts. Unfortunately, these were mostly salts of organic acids, which are well known to produce no effect upon the E.M.F. Very decided changes, however, are often observed in passing from one halogen salt to another, and this fact led Bancroft* to the conclusion that, although a single E.M.F. is independent of the concentration when ions of the metal are not in solution, and also generally independent of the positive ion in such a case, yet it depends upon the negative ion and upon the solvent. He concluded further that in aqueous solutions the E.M.F. is the sum of two terms, one due to the electrode and the other to the negative ion. For most metals and most electrolytes the term due to the negative ion has the same arithmetical value and the same sign; but in the case of mercury the sign is opposite, although the value is the same. A. E. Taylor† arrived at the conclusion that a single E.M.F. is not a function of the negative ion; he looks upon mercury and copper as exceptions, the effect in these two cases being probably due to the formation of complex salts.

ON THE SIMILARITY OF EFFECT OF ELECTRICAL STIMULUS ON INORGANIC AND LIVING SUBSTANCES.‡

BY PROF. J. CHUNDER BOSE, D.SC.

(*Concluded from page 865*).

ON THE STRAIN AND ELECTRIC THEORY OF VISION.

Two theories may be advanced to explain the phenomenon of visual impulse.

1. *Chemical Theory.*—It is supposed that vision originates from the metabolic changes produced in the "visual substances" in the retina, the metabolic changes consisting of two phases, the constructive or anabolic phase and the destructive or katabolic phase. The theory, as will be seen, is very complex, and there are certain difficulties in the way of its acceptance. It is difficult to see how the quick visual process could be due to the comparatively slow chemical action, consisting as it does of the breaking down of the tissue followed by its regeneration. The bleaching action of light on the visual purple gave some support to the chemical theory; but it has been found that the presence or absence of visual purple is not of essential importance to vision. For it is well known that in the most sensitive portion of the human retina, the *fovea centralis*, the visual purple is wanting. The visual purple is also completely absent in the retina of many animals possessing keen sight.

2. *Electric Theory.*—According to this theory, the visual impulse is an electric impulse (an electric impulse in the optic nerve is known to produce visual sensation). The nerve is a conductor of electric current, and the brain an extremely delicate detector of current. I now come to the consideration of the most difficult part of the subject as to the production and regulation of visual current in response to the fluctuating stimuli of the incident light on the sensitive substance in the retina. The visual current may be produced in two different ways.

I have said that the effect of radiation stress is to produce a molecular strain which may give rise to either an electromotive variation or to a variation of conductivity. Imagine an elementary voltaic cell in the retina, composed of two similar elements immersed in an electrolyte, and imagine one of these elements to be more exposed, and therefore more strained by radiation. The difference in the strain of the two elements will give rise to an E.M.F. In this case the varying current impulse is directly due to the strain effect of radiation.

Or we may have an independent E.M.F. already existing in the retina, and the visual current may be supposed to be regulated by the conductivity change (also due to molecular strain) of an interposed sensitive substance under the action of radiation. In connection with this is Prof. Lodge's very important coherer theory of vision, which explains in a simple manner the production of visual impulse by the sudden change of conductivity due to coherence. This very suggestive theory labours, however, from the insufficiency of the coherer theory itself. The automatic visual recovery, the formation of positive and negative images, and the various phenomena connected with after-effects cannot be explained from the simple coherence theory. It will presently be shown that all these phenomena may be explained from the theory of molecular strain.

The choice of either the electromotive or the conductivity variation hypothesis is to be determined by the consideration as to the presence or absence of an independent E.M F. in the retina. The

‡ Abstract of a Paper read before Section A of the British Association at Bradford.

Digitized by Google

experimental verification of this question is very difficult, owing to the disturbing effect of the current of "injury." The experiments of Dewar and McKendrick show that an eye current exists when two electrodes are connected, one with the coronea, and the other with the cut end of the optic nerve. Here the effect of injury is present; (the most important result established by the above investigations is the *variation* of retinal current by light). In order to reduce the effect of injury, I carried out experiments with the two electrodes fixed on the retina itself, so that the two injury effects might neutralise each other to a more or less extent. Under these conditions, I obtained a retinal current; it cannot, however, be assumed that the two effects of injury at the two electrodes were exactly similar. The feeble visual sensation, even in the dark, known as the "intrinsic light of the retina" seems, however, to point to the existence of an accidental or real E.M.F. in the retina.

In any case, the visual current is due, directly or indirectly, to the strain effect produced by radiation. If the visual circuit does not contain an E.M.F., then the electromotive variation due to strain, suffices to explain the visual effect; if there is an E.M.F. in the circuit, then the conductivity variation regulates the visual impulse.

On an Artificial Retina.

I have been able to construct several curious receivers which are sensitive to radiation, and also exhibit an automatic recovery. One of these responds not only to visible, but also to invisible lights. It is very strongly affected by electric radiation; the same receiver responds not only to heat radiations, but also to different coloured lights. The action of this receiver is probably somewhat complex, and for the present I will deal with the simple receiver made of magnetic oxide of iron, which was shown to be sensitive to electric radiations and to exhibit, when slightly warm, an automatic recovery.

Parallel Experiments with the Artificial and the Real Retina.—I will presently describe the effects produced on the artificial retina by radiation of varying intensity and duration, and will also give some typical curves based on quantitative measurements. For the purpose of comparison it became necessary to carry out a corresponding set of experiments with the eye. In this I at first met with great difficulties. For example, from the analogy of the somewhat permanent distortion (attended with increased conductivity) produced in the sensitive substance by the action of intense electric radiation, I imagined that the particular portion of the retina, on which an image was formed of a strongly luminous external object, would remain sub-permanently conducting even after the removal of the source of light. In that case I thought it would be possible to revive the perception of the image by applying an E.M.F. to the eye. The difficulty was in the application of an external E.M.F. to the retina. I attempted applying the electrodes of a voltaic cell to the eye thinking that the retina acting as a shunt might allow a portion of the current to pass through it. I was, however, obliged to desist from further experiments in this direction, owing to the extremely irritating effect of an external E.M.F. on the eye.

It then occurred to me that if the visual circuit is an electric circuit, then it is not at all necessary to apply an external E.M.F., that the strain effect in particular portions of the retina on which the image was formed could be demonstrated by the current effect which might persist, since the recovery of sensitive substances is not instantaneous; in that case all one need do is to shut one's eye immediately after exposure to light to perceive the after-effect; closure of the eye makes it certain that the observed effect is due to the light stimulus immediately preceding, and not to other disturbing causes. In adopting this method, it did not strike me at the time that I was straying into obscure region of after-images. This has been of advantage to me, for not knowing exactly what to expect and free from any preconceived bias, I was better able to observe the various after-effects and notice several phenomena which are perhaps novel. I will in each of the following sections first describe experiments with the artificial retina under (a); the corresponding experiments with the eye will then be described under the section (b).

It is to be borne in mind that the visual sensation in the dark is not, as previously mentioned, one of intense darkness; there is even then a very feeble sensation of light, known as the intrinsic light of the retina; this shows the existence of a natural feeble current in the visual circuit. Suppose, now, the visual current is by any means increased there would then be produced a corresponding increase in the sensation of light; similarly, if the retinal current corresponding to the intrinsic light is in any way diminished, there would be produced a sensation of darkness more intense than the mere passive sensation of darkness in the absence of light.

Effect of Radiation of Short Duration.

I give two curves (α) and (β) for the magnetic oxide receiver; in (α) the electric radiation was near the receiver, and a single flash of intense radiation was allowed to act. In (β) the intensity of the incident flash of radiation was reduced by removing the radiator further away. It will be seen—

(1) That there is a very short latent period;

(2) That even after the radiation is cut off the curve continues to rise, *the maximum effect being produced some time after the cessation of radiation.*

(b) *Maximum after-effect.*—Now for visual analogue. We may take a tube at the end of which is fixed a glass disc coated with lampblack, on which, by scratching with a pin, some words are written in transparent characters; the other end of the tube is applied to the eye. Turn the blackened disc towards a strong source of light, with an interposed cardboard. By a quick movement of the latter a short exposure is given; the eye which saw the transparent letters for a moment is immediately closed. It will now be found that there is at first hardly any well-defined visual sensation; the maximum effect being produced some time after, it will be noticed that the after sensation of the luminous characters gradually attains a maximum intensity and then fades away.

(b^1) *Positive after-image.*—If the closed eye be turned towards a well-lighted landscape and the eyelids suddenly opened and closed, the *positive* after image will be distinctly seen. It would be advisable to bear in mind the different nature of the stimuli that cause the positive and the negative after images. In the case described above, the stimulus is of short duration, the light being cut off before the maximum effect is attained; *in such a case the after-effect is positive, there being no reversal or interval of darkness between the direct image and the after image, one being merely the continuation of the other.* It will be shown that in the other type of after image there is an intervening reversal.

(3) From an inspection of the two curves it will be noticed that the maximum effect is attained much more quickly and the ascending curve is steeper, and the decline from the maximum is earlier and more rapid (at least in the first part) with intense radiation than with feeble radiation. Hence it follows that with intermittent

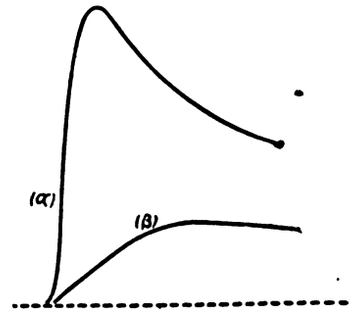

Fig. 10.—Effects due to (a) to Strong Radiation (b) to Feeble Radiation.

radiation, at a certain rate of interruption the curve of action for feeble radiation may be continuous, whereas for the same rate the curve for strong radiation will be jagged; in other words, a "flicker" will be produced in the latter case.

(b) *Visual flicker due to Intermittence.*—Now the visual flicker due to intermittence is precisely similar. In the phenomenon of vision "the interval between successive stimuli at which fusion takes place and flicker disappears *varies according to the intensity of the light, being shorter with the stronger light.* When a brighter illumination is used the rapidity (of intermittence) must be increased before the flickering disappears; *this is owing to the decline of the stronger sensation beginning earlier and being more rapid than that of the weaker sensation.*"*

Effect of Continued Action of Moderately Strong Radiation.

I have previously described the summation effect of rapid succession of radiation stimuli on inorganic sensitive substances.

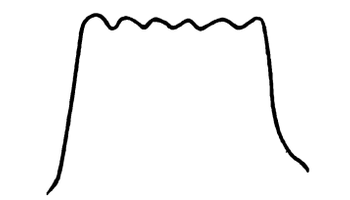

Fig. 11.—Tetanic Effect in Fe_3O_4 Receiver produced by Continuous Radiation.

It was shown that under such circumstances the individual effects are fused together, and there is produced a "tetanic" effect which gives rise at first to a continuously ascending curve. It was also shown that the elasticity increases with the increasing strain, and that in the neighbourhood of maximum strain the curve tends to become horizontal; that there is a fluctuation in this portion of the curve; and, lastly, on the cessation of stimulus the fall curve is very steep, specially in the first part of the fall. Now a continuous light

* Foster "Text-book of Physiology," p. 1,327.

Digitized by Google

is in reality a rapid succession of radiation impulses, and we may therefore expect an effect of a tetanic nature to be produced by it.

I now pass on to the corresponding visual phenomena.

(*b*) (1). In the curve given above, the first part is ascending; when the *maximum is reached there is a fluctuation.* With the eye, the first part corresponds to an increasing sensation of light. At the maximum stage the curve is horizontal. This explains why it is easier to distinguish a slight difference between two feeble lights than the same difference between two bright lights. After the maximum stage, the fluctuation would correspond to a visual flicker. This flicker is to be distinguished from that due to intermittence. I have been able to detect this curious flicker effect by a special method to be presently described.

After-Oscillation and Visual Recurrence.

As the strained substance is set free on the stoppage of radiation from the distorting force, it rebounds towards the normal state, and in so doing may, under certain circumstances, overshoot the position of equilibrium and an oscillation may thus be produced. With the magnetic oxide of iron the rebound towards recovery sometimes carries the curve below the original conductivity, but there is little further oscillation. In living substances, however, the after-vibration is more pronounced, and in the retinal substance the after-oscillation is very persistent. It is to be remembered that the number of oscillations which can be detected depends not only on the intensity and duration of the stimulus, but also on the sensitiveness of the detector; allusion has already been made of the extraordinary sensitiveness of the brain as a current detector.

It is evident how these oscillations cause current impulses in the visual circuit which are alternately weaker and stronger than the normal retinal current (which corresponds to the intrinsic light of the retina); a diminished current would produce a sensation of darkness, and an increase of current would mean an increased sensation of light. The after-oscillation would thus give rise to recurrent series of negative and positive images.

If we look for a long time at a bright object (preferably with one eye) and then close the eye, there is an immediate *dark sensation* due to the rebound. This is unlike the effect with short exposure, where the immediate after-effect is positive. With long exposure, owing to the steep fall of the curve, the immediate after-sensation is, as has been said, one of darkness; the subsequent oscillations then give rise to a recurring series of images.* A more detailed account of this phenomena will be given under "Binocular Alternation of Vision."

I will now proceed with certain phenomena connected with after-oscillation. In my fuller Paper will be found accounts of other interesting effects produced on the artificial retina, which throw much light on several obscure visual phenomena, such as the chromatic after-effects, the reversal effect due to radiation below the critical intensity, the recurrent reversal effects and irradiation.

Binocular Alternation of Vision.

In the curve for the artificial retina there was seen a fluctuation after the maximum stage was reached. It is, however, difficult to detect the corresponding visual fluctuation owing to a very remarkable pecularity of binocular vision. When we continue to look at an object with both the eyes there is produced a fluctuation in each eye. The fluctuations are, however, not coincident in the two eyes, there being a difference of half a period between the two. It thus happens that one eye, as it were, gradually falls asleep, while the other wakes up to the maximum consciousness; the second eye then gradually ceases to see, while the sensitiveness of the first gradually waxes to a maximum. The visual effect in an individual eye undergoes fluctuation from moment to moment and in such a way that the sensation in the one eye is complementary to that in the other, the sum of the two sensations remaining approximately constant. In this way the two eyes take up the work of seeing and taking rest alternately. This relative retardation of half a period in the effects produced in the two retinas is extremely curious. It is evident that this alternate division of labour in binocular vision is of much advantage to the animal economy. Ordinarily, the effect described above is not noticed, owing to the summation of the two partial effects in the brain, and also to the exposure of fresh portions of the retina by the constant movement of the eye. But the phenomenon is clearly brought out by the experiment to be presently described, in which it was necessary to pay particular attention to the following points:—

1. That a definite portion of the retina should be exposed to light, and this was to be secured by preventing any movement of the eye.

2. That the impression produced on the two eyes should be kept distinct, so that the effects produced could be subsequently compared.

3. It was also necessary that the two eyes should be kept in a state of relative ignorance, so that there could be no question of predisposition or judgment.

For carrying out the above conditions, I took a stereoscope, and provided the ocular ends with two soft pads, with small circular apertures through the centre for looking through. The eyelids rested lightly on the pads; any unconscious movement of the eye was thus partially prevented. It is indeed very difficult to keep the eye from unconscious movement, but the friction thereby produced against the pads at once gives timely warning of the tendency, which may then be easily checked. The partition inside extends right up to the design which is to be looked at. The design consists of two slanting cuts in a blackened cardboard at a suitable distance from each other, the one cut, R, slants to the right, and the other, L, to the left. When the design is looked at through the steroscope the right eye will see, say, R and the left L; the two images will appear superimposed, and we then see an inclined cross. The object of making the cross inclined is to distinguish the after-image of this particular form, from the visual memory of the erect cross.

When both the eyes are open, what the eyes see is the complete cross, it being impossible for the individual eye, say the right, to find out whether it is the image of the right or the left arm of the cross that is formed in it. At the end of the experiment one eye may be closed and the component of the cross thus localised.

When the stereoscope is turned towards the sky, and the cross looked at steadily for some time, owing to the alternation referred to above, it will be found that while one arm of the cross begins to be dim, the other becomes bright and vice versa. This alternation could not be due to any "rivalry" or struggle between the two eyes, for there is nothing particular to struggle about, nor can this be due to any difficulty of accommodation at the same time for two different colours, for the two slits are illuminated by the same light of the sky.

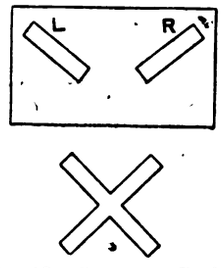

Fig. 12.—Sterescope Design.

The alternate fluctuations become far more prominent when the eyes are closed; the pure oscillatory after-effects of the strained sensitive molecules, unaffected by the disturbing effect of further light stimulus, are then obtained in the most vivid manner. To observe merely the oscillation, one eye may be used for observation; after exposure and subsequent closing of the eye, it will be found that the slanting arm of light appears and then disappears. To observe *alternation*, both eyes look at the pattern in the cardboard in the manner described above. After an exposure of 10 seconds or more, the eyes are closed. It is to be noted that the two retinas are subjected to the same length of exposure, and the length of nerves that convey the visual impulse are the same in the two eyes. The first effect after closure of the eye is one of darkness due to the rebound. Then one luminous arm of the cross projects aslant the dark field. As every portion of the retina is not equally sensitive, the after-image is not instantaneously formed in the field, but appears to jut out from one end to the other. This arm now slowly disappears, and then the second arm of the cross (produced in the other eye) shoots aslant the field. This alternation proceeds for a long time, and produces the curious effect of two luminous blades crossing and re-crossing each other. Owing to the relative retardation of after-effect due to different coloured lights, the two crossing blades successively exhibit a gorgeous display of chromatic effects.

There are several very interesting investigations rendered possible by the method of binocular alternation; of these I mention a few, the detailed accounts being postponed for a future occasion. It has been shown that under normal condition the two retinas have a relative natural retardation of half a period. Now if one retina be kept under standard condition, and the other subjected to a different condition of temperature, pressure, different lengths of exposure to different coloured lights, &c., then the natural retardation of half a period will be disturbed; one oscillation being accelerated or retarded will gradually overtake the other or be overtaken by it. Hence from such "beats," the effect of various influences may be studied.

There are several other ways in which the alternation of vision may be demonstrated. One striking method is to look at two different sets of writing with the two eyes; the resultant effect is a blur due to superposition. But on closing the eye the complex image is analysed into its component parts.

* For two other methods of observing recurrent phenomenon of vision see Charpentier (*Phil. Mag.*, 1891, p. 397) and Bidwell (*Proc.* Roy. Soc., June, 1894). Mr. Bidwell describes a beautiful method where the "ghost" follows the trail of the primary light stimulus.

An Important Element of Retinal Fatigue.

While describing the peculiarity of the magnetic oxide receiver it was shown that the rise curve for feeble stimulus is very gentle, whereas the fall curve after strong stimulus was very steep. It is thus easy to see that the feeble radiation stimulus is unable to arrest the rapid fall which follows as an after-effect of strong radiation. This inference I have been able to verify with the magnetic oxide receiver. The above considerations explain certain type of the fatigue of the eye, the phenomenon being a little different from the other fatigue phenomenon hitherto studied. For in addition to the partial loss of sensitiveness due to the overstrained condition of the sensitive elements, there is added a rebound which gives rise to a negative image. When we stare for a long time at a white patch on a dark background and then turn the eye to a moderately lighted wall, we see a grey or dark patch corresponding to the original white patch.

Theory of Exhaustion.—It is usually supposed that the portion of the retina affected by light is "tired," and a negative image is formed owing to exhaustion. If we try to find the meaning of the figurative terms used above, we may, from analogy of muscles, suppose the exhaustion to be due either to the presence of "fatigue stuffs" or to the breaking down of the sensitive elements, or to both. The above explanation leads to the conclusion that the fatigue and the consequent negative image should gradually and finally disappear and the retina thus restored to the normal condition.

Theory of Strain.—But if the fatigue is due to the strained condition of the retinal substance, then we may expect an oscillation as an after-effect: a rebound towards the negative stage, to be followed by a springing back to the positive stage, and these to alternate for some time. The negative image should not, on the above supposition, finally vanish on the first disappearance, but ought to disappear and re-appear in succession.

We have thus a crucial test for the two theories, and the test consists in finding out whether the disappearance of the negative image is non-recurrent or recurrent. If we look for a time with one eye at the slanting arm of the cross in the stereoscope, as described in the previous section, and then turn the eye to a dimly lighted wall, it will be found that the dark negative arm of the cross gradually disappears; but this is not all, the negative image after a while again appears (with an intervening positive image) and then disappears, and this recurrence continues for a considerable length of time. From this experiment it is seen that the theory of strain alone explains the observed effects in a simple and satisfactory manner.

There are other interesting experiments by which the binocular alternation may be exhibited; of these I will here mention one. If the cross be looked at for a long time through the stereoscope with both the eyes, and we now turn one eye, say the left, to the wall, keeping the other eye closed, there will be seen, as mentioned before, the negative and the positive images of one arm of the cross in succession. When the intensity of the negative image with the left eye is a maximum, if we suddenly open the right eye (and close the left eye) the positive after-image will be seen; but if the right eye is opened when the positive image with the left is a maximum, then the image seen by the right eye will be negative.

On Certain Phenomena Analogous to Memory.

The gap which at present exists between the physiological and the beginning of psychological processes is very wide. Some transitional phenomena may perhaps be found to bridge over the discontinuity. Certain effects will now be described which appear to be very suggestive. I need only add that the deductions drawn are mere inferences, and as such are to be regarded with caution.

In the experiment with the stereoscope and the design of the cross, the after-images of the cross are at first very distinct—so distinct that any unevenness at the edges of the slanting cuts in the cardboard can be distinctly made out. There can thus be no doubt of the "objective" nature of the impression made on the retina, which consists in the strain produced in the sensitive particles. The objective nature of the strain is further seen after the stoppage of the light stimulus; a twisted wire suddenly released gives rise to oscillation, and the suddenly-released strained particles in the retina give rise to a similar oscillation, as is demonstrated by the phenomenon of recurrent vision. This recurrence may therefore be taken as a proof of the physical strain produced on the retinal substance by light. The after-image of the cross is, as has been said before, very distinct at the beginning, and becomes fainter at each repetition; a time comes when it is difficult to tell whether the image seen is the objective after-effect due to strain or merely an effect of "memory." In fact, there is no line of demarcation between the two, one simply merges into the other. That this "memory" image is due to objective strain, is made evident by its recurrence. How long does the objective impression on the visual centres last? The answer to this could only be given if we knew the limit of sensitiveness of the brain. We know that under favourable circumstances it can detect impulses which are extremely feeble. I have many instances where the persistent nature of these after-oscillations appeared long after, as spontaneous memory revivals. Thus a friend repeated the experiments with the stereoscope and the design of the cross; he watched the recurring after-images for a long time till they failed to be seen, owing to "certain feeling of irritation in the brain." This was in the afternoon, and my friend spent the evening in other occupation, having in the meanwhile completely forgotten all about the experiment. But at night, preparing to go to sleep, he noticed all of a sudden the recurrent image of the cross. Putting out the light and closing the eye made matters worse; the image instead of being shut out became all the more vivid. This went on for a very long time. In the case mentioned above, it is noticeable that the image, owing to other distractions, remained unperceived, and became only visible as soon as they were removed. In another case the recurrence was observed in a dream, about three weeks after the original impression was made.

In the cases just described, owing to the definite and somewhat unusual nature of the image, it is not difficult to connect the "memory image" with the objective impression previously made. But in other cases of spontaneous revival the connection is not so evident. "Not only single and simple sensations, but also complex group of sensations may be excited by other means than that of light falling on the retina, and we may thus experience varied and intricate perceptions which have no objective reality at all. . . . . Sometime the sensations and perceptions thus occurring, specially those which are met with on closing the eyes at night, *may be recognised as revivals more or less altered of sensations experienced during the day*; something sets going again the series of cerebral events which were set going by actual rays of light."* I have explained by what mechanism the recurrent phenomenon may have been set a-going.

In the experiment described at the beginning, it was shown that the after-effect phenomenon of retinal impression merges into the phenomenon of memory. Are the two identical, at least in many cases? One peculiarity of retinal impression is its recurrence. Now it is interesting to observe that the phenomenon of memory is also recurrent. "Certain sensation for which there are no corresponding processes outside the body are generally grouped for convenience under the term (memory). If the eyes be closed and a picture be called to memory, it will be found that the picture can not be held in memory, but will repeatedly disappear and appear."†

Conclusion.

I have shown how the theory of molecular strain explains in a satisfactory manner the varied phenomena connected with the molecular receivers. The effects are seen to be perfectly regular and not capricious, as is generally supposed. The method of conductivity variation affords a new and powerful means for the study of many molecular phenomena at present beyond the means of investigation. The extension of the hypothesis of molecular strain will, I am convinced, afford satisfactory explanations of many obscure physical problems, and will bring together, under a simple generalisation, phenomena which at present are regarded as entirely disconnected. In support of the above I have obtained very interesting results which I hope to publish at an early date.

Passing from the physics of inorganic substances to that of living tissues, we enter into a field of phenomena where an antecedent event is followed by a chain of reactions of the most complex kind. The strain produced by an external stimulus in a portion of tissue may, for example, give rise to variation of electric potential; this leads to volta-chemical action and the chemical combination product may in its turn act as a poison. The final result may thus be a very complicated one. But at the root, and as primary cause and effect, we find the stimulus or stress and the corresponding strain. From such a consideration a series of diverse phenomena obtain the most simple explanation. It has been shown how the stress and strain phenomena in living tissues appear to be but repetitions of similar phenomena in inorganic substances. Are the resemblances merely chance coincidences? They are too numerous and too consistent to be due to mere chance; they rather point to some fundamental similarities.

Matter when overstrained by stimulus recovers slowly. This overstrain produces the same fatigue in inorganic matter as in the living tissues of our own body. Vibration removes the fatigue in both.

Injection of certain foreign substances may either by increasing the viscosity or diminishing the elasticity cause partial or entire loss of recovery and subsequent response; this effect is seen to be produced in both living and non-living forms of matter. Injection of other substances may give rise to the opposite effect of an increase of excitability.

On the cessation of stress the substance may rebound; this gives rise to a fluctuating current in the retina, attended by the phenomena of recurrent vision; the persistent oscillatory after-effects due to previous strain may give rise to the beginning of the psychical process of memory.

In the phenomena described above, there is little breach of continuity. It is difficult to draw a line and say "here the physical

* Foster, "Text-book of Physiology," p. 1,387.

† E. W. Scripture, "The New Psychology," p. 101.

Digitized by Google

process ends and physiological process begins" or "that is a phenomenon of inorganic matter and this is a vital phenomenon peculiar to living organisms" or "these are the lines of demarcation that separate the physical, the physiological and the beginning psychical processes." Such arbitrary lines can hardly be drawn.

We may explain each of the above class of phenomena by making numerous and independent assumptions; or finding some property of matter common and persistent in the living and non-living substances, attempt from this common underlying property to explain the many phenomena which at first appear so different. And for this it may be said that the tendency of science has always been to attempt finding, wherever facts justify it, an underlying unity in apparent diversity.

THE ACCURATE MEASUREMENT OF ALTERNATING AND MULTIPHASE CURRENTS.*

BY G. L. ADDENBROOKE.

For many years past I have given much attention to this subject, and I have now the honour to lay the results of my experience and work before the International Congress. One main point which struck me several years ago was the desirability of looking at the question as a whole. In measuring alternating currents it is necessary to take into account the fact that if there is inductance or capacity in the circuit, as is usually the case, the current which flows is influenced by three factors: (1) The resistance of the circuit and the work done within it; (2) the inductance of the circuit; (3) the capacity of the circuit. The inductance and capacity effects being exactly opposite in phase, counterbalance each other as far as they can, the larger factor predominating, the phase of which will be either 90deg. behind or in advance of the phase of the energy current, according as the self-induction or capacity of the circuit predominates. This current, when further combined with the energy current, produces a resultant current which is that actually flowing in the circuit, and which I prefer to call the "total" current rather than the "apparent" current and which, it is clear, will not be in phase with either of its components.

In carrying out measurements in practice, the wattmeter principle has come to be almost universally used in practice. Assuming that this principle is the one employed, there are three measurements which must be made to obtain the fundamental factors of an alternating current. When these factors are known other characteristics of the current can be deduced. A measurement must be made of: (1) The impressed volts; (2) The apparent amperes, or as I prefer to call them, the "total" amperes; (3) the effective amperes or wattts. (If the effective watts are measured, knowing the impressed volts we can directly deduce the effective amperes.)

Having these quantities, we can directly deduce in addition the power factor, the angle of lag, and the magnetising or capacity current or their resultant, if both are present. Also, if we know the periodicity, the coefficient of self-induction of the circuit and other characteristics may also be obtained without further observations. Finally, if both inductance and capacity are present, by measuring the capacity we can with the above data find the inductance.

To adapt the electrometer for use as a wattmeter I insert a series non-inductive resistance in the circuit to be measured, across which the quadrants are connected, while the needle is connected to the other side of the circuit so that the potential difference of the circuit is established between the needle and the quadrants. By arranging the instrument in this way and calibrating it properly, it is possible, under the right conditions, to make the electrometer a direct-reading wattmeter. Having the above-mentioned resistance necessarily in the circuit, it was clear that if it were possible to make an electrostatic voltmeter sufficiently sensitive to measure the drop of volts across this non-inductive resistance such an instrument so coupled would become a very handy form of ammeter. I have been able to attain such sensitiveness in the instrument employed as an ammeter that it is possible to get good readings with a drop of from 1 volt to 2 volts across the non-inductive resistance inserted in the circuit. As a matter of fact, I am arranging my instruments in practice now so that the non-inductive resistance inserted in the circuit shall cause a fall of potential of about 1½ volts as an average, which answers very well for the wattmeter also; this is a handy drop because it approximates to the E.M.F. of a Clark cell which is used for standardising the instruments, and consequently the readings come near the portion of the scale for which the instruments have been standardised. To attain this object, namely, to always obtain a good deflection on the instrument, a set of non-inductive resistances formed of strips of maganin are used. These strips in practice are about a metre long, and a handy way to arrange them is by beginning with a wire or strip to carry, say, one ampere, to make the next strip carry about two amperes, and the third four amperes, so that about ten strips will usually cover the full range of currents which are likely to be required in practice. For special purposes, of course, higher or lower resistances can be made, and since the instruments take infinitesimal currents, the same set of instruments will measure currents varying from, say, $\frac{1}{1000}$th of an ampere to 1,000 amperes or more, with equal percentage of accuracy in each direction if required; consequently the instruments are practically universal in this respect. By arranging these resistances so that they can be placed in parallel, the same deflection approximately on the instruments may, if desired, always be worked to.

As regards the measurement of currents of high voltages, there are two ways of proceeding. The instruments themselves can be made so that they can be directly connected to the high voltage circuit, but I usually prefer to employ instruments standardised for working direct on circuits of from 100 volts to 200 volts as a standard; and for higher voltages, to connect a high non-inductive resistance across the circuit, making the instrument connections across some known fraction of this over which there is a fall of 100 volts or 200 volts.

It now remains to describe this method and the design of the apparatus and instruments, and to show how they are used and

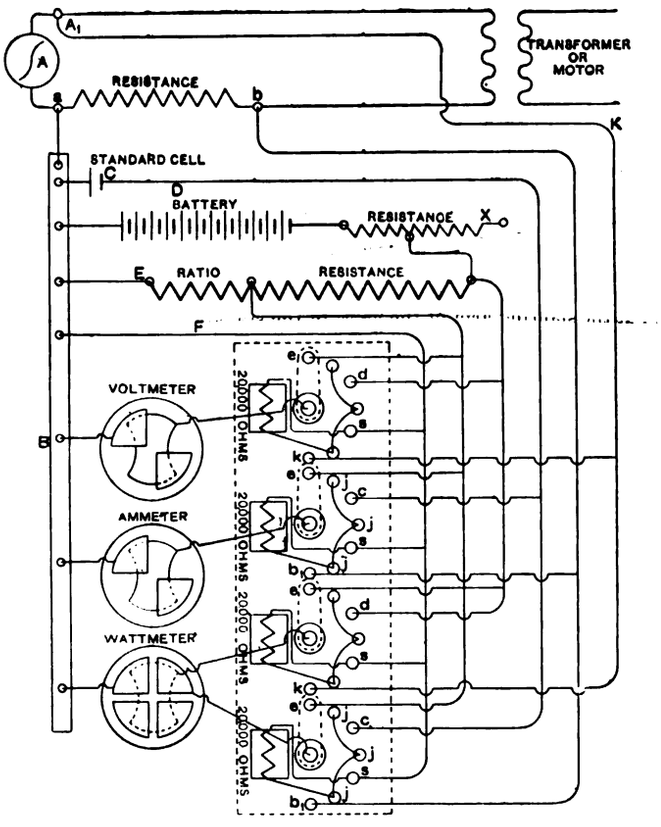

FIG. 1.

applied to the purpose in view. Fig. 1 is a diagram showing the method of connecting the instruments in practice to a circuit on which measurements are to be made, and the figure also shows diagrammatically the method of standardising the instruments and the switching arrangements by which the different connections are made, this is done by merely turning certain handles after the instruments are once set up.

In the diagram, A indicates the alternating-current generating machine having a main circuit A_1, wherein is placed a non-inductive resistance *ab* as mentioned above. From the point *a* a connection is shown to an omnibus bar or common terminal bar B to which most of the circuits hereinafter mentioned are joined. These are best arranged in the following order: C is a standard Clark cell, D is a battery of sufficient power to give rather more than the maximum voltage required for standardising the in-truments. I find a battery of small accumulators very convenient for this purpose, but if such a battery is not accessible the instruments can be standardised by making use of an electric lighting circuit instead, provided that readings are taken at similar pressures, which can be observed by connecting the electric light circuit to the voltmeter while readings on the wattmeter are being taken. X is a variable resistance in series with the battery. E is a box of resistance coils so arranged that a resistance of 100,000 ohms is always maintained between the

* Abstract of a Paper read at the International Electricity Congress at Paris.

Digitized by Google

terminals, but by means of movable switches a third connection can be made to the resistance at any point desired. The outside terminals of this, which I call the "ratio" resistance, are connected to the common bar and to the resistance X, so that the ratio resistance forms a shunt across the battery and the resistance X. Let us suppose that the E.M.F. of the battery is 105 volts. By altering the resistance X suitably we can so arrange matters that there is exactly 100 volts pressure between the outside terminals of the ratio resistance E, under which circumstances we can, by setting the switches of the ratio resistance to the proper points, obtain any voltage we like accurately between 0 and 100 volts. F is a short-circuit connection between the bar B and a terminal *s* in each of the switches indicated below whereby any of the instruments may be short-circuited and their zeros adjusted. The electrostatic voltmeter, ammeter, and wattmeter are also connected to this bar. The voltmeter switch has four terminals, *e*, *d*, *s*, and *k*, the terminal *s* short circuiting the instrument as above stated. With the switch in contact with the terminal *d*, the instrument is connected to the battery D; and, similarly, when in contact with the terminal *e*, the switch puts the instrument in connection with the ratio resistance E, so that a desired part or ratio of the whole resistance can be measured off and any required voltage within the limit of the battery put upon the needle *g* of the voltmeter G, its quadrant plates s_1 being connected to the bar B. By this means the voltmeter can be calibrated throughout the whole length of its scale. The terminal *k* serves to place the needle *g* in connection with the circuit K, on which measurements are to be made.

The ammeter switch s_1 is provided with four similar terminals, indicated by the reference letters *e*, *c*, *s*, and b_1. The terminal *c* is for connecting the needle h_1 with the standard cell C. The terminals *e* and *s* correspond to the similar terminals of the voltmeter switch, and the remaining terminal, b_1, connects the ammeter to the main circuit A_1, at the *b* end of the measured non-inductive resistance *ab*. The wattmeter has a double set of switch terminals, one set, *e*, *d*, *s*, *k*, being exactly the same and with the same circuit connections as for the voltmeter, and the other set, *e*, *c*, *s*, b_1, being similar to those of the ammeter switch.

In changing the instruments from one set of connections over to the other, it is very desirable to have a means of separately short circuiting each of the instruments through a high-resistance of about 20,000 ohms while the operation is performed, otherwise the quadrants must be left unconnected for a period of time, which sometimes leads to violent deflections of the needles when connected to alternating currents and from charges on the ebonite or other adjacent surfaces otherwise difficult to avoid. This is provided for by the intermediate contacts *jj*... in each of the switches, as shown in the figure, which are connected to bobbins containing a resistance of about 20,000 ohms, one for each set of switch contacts.

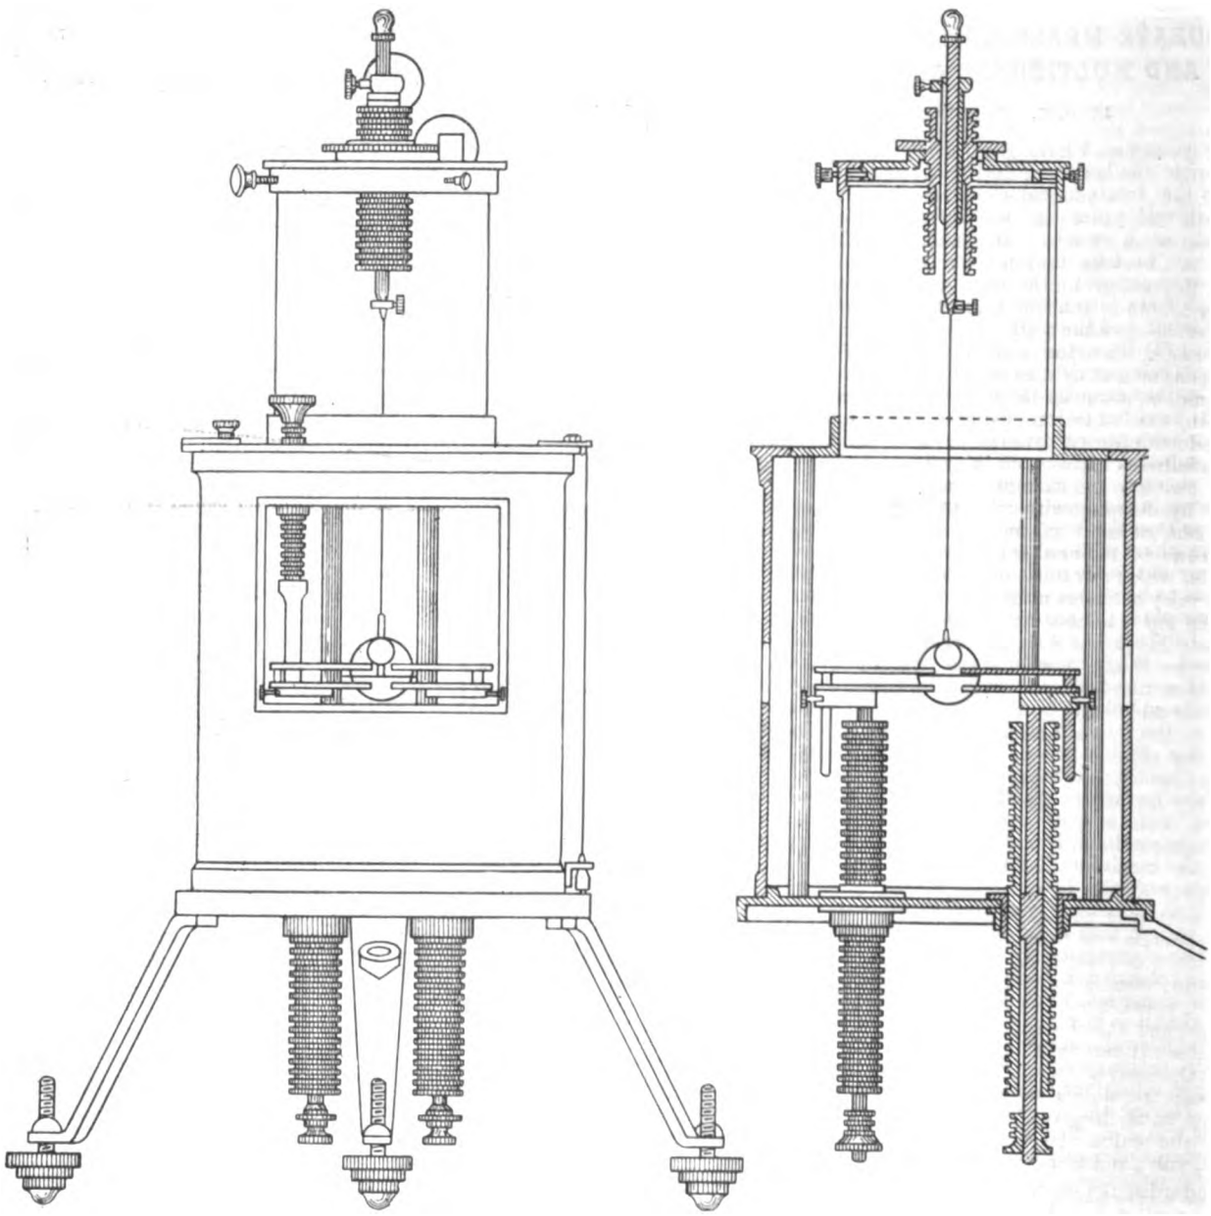

FIG. 2.

We now come to the instruments themselves. They are electrostatic, and are all built on the same general lines, which can best be seen by referring to Fig. 2, which represents the wattmeter. It may be noted that this one instrument will perform also the functions of a voltmeter and of an ammeter or low-reading voltmeter by simply altering the suspension of the needle and appropriately adjusting the quadrants. The instrument as shown is provided with a very high insulation, so that it can be used for measuring high resistances, capacities, &c., but such insulation is not specially necessary where

Digitized by Google

the instrument is to be used for measuring currents only, or as a low-pressure voltmeter.

The suspension consists usually of a flat phosphor bronze strip of the kind which was brought into use by Messrs. Ayrton and Perry and which is so largely used in connection with the d'Arsonval galvanometer. This, of course, forms an excellent connection to the needle, so that there is no necessity to use sulphuric acid. Further, by using a specially light needle, I find that I can get sufficient decrement without any other form of damping, and consequently the needle may hang perfectly free in air, and there is nothing which can interfere with its proper movement in any way. It will be noticed that the quadrants are not made in the form of a box, as is usually the case, but consist of two sets of flat plates, the one set of which, usually the upper, is adjustable and can even be taken off altogether if required. This simple improvement, while it does not interfere with the action of the instrument in any way, greatly increases its range, adjustability and portability; in fact, it is much like adding an universal shunt to a galvanometer. The needle, it will be noticed, can be moved up and down by means of a rack motion, and can thus be set in the centre of the quadrants whatever the action of the upper and lower plates. For high voltages the upper plates can be removed altogether, and the needle removed some distance from the lower set of quadrants. On the other hand, the needle may be brought down close to the bottom set of quadrants and the top set brought down until the space between is not more than a millimetre. Under these conditions a deflection of 50mm. to 100mm., with the scale at a distance of 2 metres can be obtained with the most sensitive strip with a pressure of 1 volt only when the instrument is connected up idiostatically or as a simple voltmeter, and it is in this sensitive form that the instrument can be used as an ammeter by coupling it across a resistance in which from 1 volt to 2 volts is lost, as mentioned above. If we take this ammeter as our basis instrument, then the wattmeter to go with it must have a thicker suspension and be used with the quadrants further apart; in fact, it should be about $\frac{1}{100}$th of the sensitiveness of the ammeter. Then, again, the voltmeter requires to be much less sensitive still, this reduction in sensitiveness being obtained by the use of only one set of quadrants and a much thicker and shorter strip, and in the latter case, owing to the strength of the torque, it is best to reduce the period by damping with oil. In each of the instruments, by taking off one or more of the top quadrants and unscrewing the centring screws of the head, the head can be lifted off, carrying with it the needle, which can thus easily be changed. For carriage it is merely necessary to let down the needle on the bottom quadrants and let down the top quadrants on the needle, which firmly clamp it, so that the instrument can be shaken or turned upside down without any damage resulting. Owing to the fact that the needles are flat and very light they are exceedingly little affected by vibration, so that the instruments can be used on upper floors and near moving machinery. In use it is well to put in the circuit of each needle a 250-volt lamp of 5 c.p. I find this better than any form of fuse, as the current which can then pass through the instrument is too small to hurt the strip or needle, and at the same time instant warning is given by the lighting of the lamp if by any chance the needle should get attracted to the quadrants. The instruments are reflecting, and I usually arrange the scales at a distance of about 2 metres from the instruments.

With the help of the standardising arrangements, approximate deflections are taken on them for the scale readings they are intended to give with given voltages on the needles and quadrants. The requisite sensitiveness is then obtained approximately by varying the distance between the upper and lower quadrants in two of the instruments, and the distance of the needle from the quadrants in the voltmeter till very nearly the deflections required are obtained. The scales themselves are on sliding supports, and the final adjustment is made by sliding the scales nearer to or further from the instruments until the given voltages produce deflections of the right length on the scales. In this way the instruments can be made to read watts, volts, and amperes directly.

To standardise the wattmeter the needle switch is turned to the battery connection *d*, and the quadrant switch to the Clark cell connection *c*, the ratio resistance being set to 1,140 (supposing the resistance is 100,000 ohms as a total and that the voltage across the ends of it is 100 volts). The quadrant switch is then turned so that the quadrants are connected to the positive end of this ratio instead of to the positive of the Clark cell, and the resistance X is adjusted so that whether the electrometer is connected to the Clark cell or to the point of ratio resistance the deflection is the same. It is obvious that under these circumstances the voltage across the outside terminals of the ratio resistance must be 100 volts. Consequently we know the voltage on the needle and the voltage on the quadrants which are the factors requisite for obtaining the constant of the electrometer. If the scale is graduated in millimetres it is now convenient to adjust the instrument and the distance of the scale, so that the reading is 144 millimetres. If this is done, then if the quadrants are connected across a resistance, the value of which is known in ohms or fractions of an ohm inserted in a circuit, and the needle is connected to the other side of the circuit, presuming the voltage does not fall very much below 100 volts then the instrument will read directly in watts when multiplied by the reciprocal of the resistance, or if the resistances are numbered by their conductivities instead of by their resistances, then we have simply to multiply the reading by the conductivity, so that the instrument becomes a direct-reading wattmeter of almost universal range. Having now got 100 volts exactly across the battery by altering the value of the ratio in the resistance, the calibration of the electrometer throughout its whole scale can be made by simply turning the resistance switches to the appropriate points. If this is done it will be found that the scale is proportionate within half per cent. over a range of about 200 millimetres, and is within 1 per cent. over 300 millimetres. It will be observed that by calibrating under the exact conditions of use we do away with the necessity of applying any formula to the deflections of the instruments.

To calibrate the voltmeter, all we have obviously to do is to put it across the whole of the ratio resistance, since the drop across this is 100 volts exactly. The sensitiveness of the instrument should then be so adjusted by raising the needle or lowering it, and by moving the scale in or out that when the instrument is so connected it deflects to the point marked 100 volts on the scale. The instrument can be calibrated for any lower reading than this throughout the scale by altering the ratio point by the proper amount.

The sensitive electrostatic voltmeter which is used as an ammeter is now calibrated by connecting it directly by means of its proper switch across the poles of the Clark cell or the corresponding points on the ratio resistance, and this instrument also can further be calibrated in the same way throughout its whole scale by using the ratio. Owing to its delicacy and construction, however, the scale of this instrument is not quite so proportionate as in the case of the other two, and therefore it is well to construct a scale for it by setting the ratio resistance at the required points and noting the corresponding deflections. This can be quickly done, and when once the scale is made the instrument can afterwards be adjusted to read to this accurately, as described for the other instruments.

The instruments are now all calibrated, and nothing remains to be done but to turn their switches to the circuit connection, when they will give direct readings on any circuit to which they may be connected, the reading of the voltmeter being, of course, multiplied by the ratio of the high resistance across the circuit (if such is used), the reading of the ammeter being multiplied by the value of the known resistance (its conductivity) in the circuit and the wattmeter reading being multiplied by both these factors.

If the circuit is non-inductive the ammeter and voltmeter readings, when multiplied together, correspond with the wattmeter reading. If the circuit is inductive this, of course, will not be the case, and if we divide the watts as shown by the wattmeter by the volts as shown by the voltmeter, then we get the effective amperes flowing in the circuit. On the other hand, the ammeter gives us the total, or as they are sometimes called, the "apparent" amperes flowing in the circuit. The ratio of these two gives us the power factor, from which, by merely consulting a table of sines or cosines, we find at once the angle of lag. If we know the periodicity of the circuit the co-efficient of self-induction can be obtained without further observation.

By having a revolving contact connected to a small synchronous motor it is obvious that by the aid of the above instruments it is also easy to take a set of readings from which the actual curve of E.M.F. and current in the circuit can be plotted, with their lag or lead.

Where great accuracy is required in the readings it is obvious that all we have to do is to take a set of readings on any circuit and then turn over the switches one by one on to the ratio resistance, altering this until the deflections of the instruments on the circuit are reproduced. We then can read off directly and without calculation the continuous E.M.F.s necessary to produce these deflections from which the value of the E.M.F. and the current in the circuit (the resistance across which measurements were made being known) is at once deduced.

It is obvious that the instruments are equally suitable for measuring continuous currents over almost any range, so that the instruments practically form a universal set of measuring instruments whether for alternating or continuous currents. They can also be used for hysteresis and permeability tests, and for a number of other purposes to which I need not more directly allude.

For multiphase work, when the circuits may be unequally loaded, two sets of resistances may be used and the instruments can be quickly switched from one to the other. Or two sets of instruments may be used. Or instruments, particularly as wattmeters, may be employed with a double set of quadrants and double needle, the top needle being insulated from the lower, which receives its charge through a jar of acid. By means of the adjustable quadrants, it is easy to make both needles deflect equally for equal charges, so that when both are employed to read together their readings are added. For other purposes it is possible to use this double instrument as a zero instrument, and balance a known continuous against an alternating voltage.

CORRESPONDENCE.

CARBON FILAMENTS AND LIGHTNING FLASHES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to Mr. Andrews' letter on the above subject in your last issue, and your own editorial note in that of the 31st ult., I think that, in view of Prof. Chunder Bose's recent deeply interesting and significant communications (significant, because his discoveries may conceivably be the first stone of the bridge which is eventually to span the gulf between the organic and the inorganic world—*Quien sabe?* The mere thought, and what it would mean, is sufficient to captivate the imagination!) on the subject of the similarity of effect of electrical stimulus upon organic and inorganic substances, we may perhaps accept the ingenious theory propounded in your editorial as being the correct interpretation of the phenomenon noticed. But we should now learn to regard the coherer, and in this instance also the carbon filaments of the lamps as "molecular receivers" of a positive or negative nature as the case may be—that is to say, substances which exhibit either a diminution or an increase of electrical conductivity under the influence of a certain degree of electrical stimulus, though it by no means follows, apparently, in the light of the professor's experiments, that they would always remain positive or negative under varying degrees of stress, and this latter consideration may possibly account for the occasional dimming of the incandescence observed by your anonymous Wisconsin correspondent. Regarding the phenomenon from this point of view, its explanation *seems* simple enough, and the gradual diminution, or the reverse, of the light again to its normal brightness after the lightning flash presents us with a visible "curve of recovery" for carbon filaments from the state of stress produced by electric discharges of infinitely great potential. It seems to me that the electric welding theory of the coherer should now go, and that we ought no longer to speak of "decoherence," but of "recovery" from molecular stress or strain, be the effects of the latter condition either of a positive or negative nature, or a resultant of both.—Yours, &c.

Oct. 1, 1900. F. ALEX. TAYLOR.

LEGAL INTELLIGENCE.

National Telephone Co. v. De Pass and Co.

At the City of London Court on Tuesday the National Telephone Co. sought to recover £50 for the use of a private telephone wire supplied to defendants, Messrs. Daniel de Pass & Co., merchants, 1, Fenchurch-buildings, London, from their City office to their branch establishment at Barking. Defendants pleaded that the wire had never been efficiently fixed; that when they used it they heard voices in the exchange, although the line was supposed to be a private one. Plaintiffs contended that the wire had been fixed as well as it was possible to fix it. Great difficulties had to be contended with in carrying the telephone service to Barking, as for 4 miles the wires had to stretch alongside the sewer bank, where the rowdier inhabitants of Barking amused themselves by throwing old domestic implements and other missiles at the wires. On several occasions whole lengths of wire had been cut off and removed. The company could not guarantee the telephone would always work. Defendants said they wanted the private wire urgently, but repudiated liability under the contract, which was for five years, as the telephone had never worked efficiently. The jury found for defendants, and Mr. Lewis Glyn for the defendants said his clients had offered, before the trial, to pay plaintiffs £25, without costs, but the offer had been declined.

South African War Fund.—Shortly after the commencement of hostilities in South Africa a fund was organised by Mr. Alfred Colson, engineer and manager of the gas and electric lighting works at Leicester, to assist the wives and children of soldiers called out to join the colours. A most satisfactory response was made, and altogether £322. 4s. 6d. was received during the 42 weeks of the fund's existence. The fund has now been closed with a balance of £101. 9s. 6d. in hand, and Mr. Colson, in a statement announcing the closing, congratulates the members of the staff on the hearty response they have made to the call for funds.

MUNICIPAL, FOREIGN & GENERAL NOTES.

Battersea (London).—An amended estimate for laying electric light mains in several chief thoroughfares has been prepared, and the Vestry have resolved to carry out the work at a cost of £1,850.

Bermondsey (London).—A resident electrical engineer will be appointed at the next and final meeting of the present Vestry. On Monday the applications already received were referred to the Electric Lighting committee in order to permit the selected candidates to appear at the next sitting.

Birkdale.—The Council have resolved to purchase the local tramways of the Birkdale and Southport Tramways Co.

Blackpool.—Parliamentary powers to construct an electric tramway along Clifton-street are to be obtained The offer of the Blackpool and Fleetwood Tramroad Co. to give a temporary supply of current for working the Corporation tramways at 2d. per unit has been accepted.

Blackrock (Dublin).—The advisability of engaging in electricity supply is being considered by the Works committee. A proposal has been made to approach the Kingstown Council with a view to erecting joint electricity works for Blackrock and Kingstown.

Bolton.—At the Council meeting on Wednesday the chairman of the Tramways committee (Ald. Nicholson) replied to various questions as to the working of the electric tramways. He said that, owing to delay in the delivery of tramcars by makers, the St. Helens Corporation had offered them a number of new bogie cars which they had built, but were not quite ready to use. Their nine months' experience of tramway working in Bolton was that, considering the sharp curves, cars on the bogie principle seemed to be the best suited for the work. The tramway track was to be relaid at an estimated cost of over £100,000, and with this and other improvements he looked forward to greater financial and other successes for the undertaking.

Brisbane (Queensland).—The committee of the Brisbane Hospital contemplate installing the electric light. At present the building provides for 300 inmates with a probable increase in the near future to 500. Communications on the subject of the proposed works should be sent to the secretary of the Brisbane Hospital, Brisbane, Queensland.

Cardiff.—The Town Council and Electric Lighting committee have at last, we are glad to see, attacked the question of friction amongst the members of the electricity staff in the right way. It was decided at last week's meeting that a good deal of the trouble with which Cardiff has been visited in connection with electric lighting matters is due to what Mr. I. Thomas described as "the unwarrantable interference of the committee in matters of petty detail." It was further decided that letters from members of the staff under Mr. Applebee's control should be referred to that gentleman and not be dealt with in committee. It must be matter for regret that this course has not been adopted from the first. There is no doubt that Ald. Sanders hit the nail on the head in expressing his "disapproval of the principle of a subordinate official making suggestions to the committee. These suggestions should be made to the recognised head of the electrical department, and that official alone should be answerable to the committee."

Carmarthen.—The Electric Light committee have decided to retain Messrs. Medhurst and Lloyd, at a fee of 50 guineas, to report upon a system of public electric lighting. In the event of electricity works being erected the usual commission of 5 per cent. is to be paid.

Cassier's Magazine.—The October issue contains articles on "The Paris Exhibition," "Electric Cables for High-Tension Service," "Transition to Electric Power," "Some Gearing for Electric Motors," and "Recent American Steam Engine Practice."

Central London Railway and the Omnibuses.—To meet the depletion in the receipts from the omnibuses on the route of the Central London Railway a reduction of fares has been made by the two leading omnibus companies, with the result that the receipts are increasing, but apparently not at the expense of the railway company, whose receipts also show an upward tendency.

Chesterfield.—Mr. R. L Acland, who was recently appointed electrical engineer to the Corporation, has taken up his duties.

Colne.—The Board of Trade have approved the system of electricity supply proposed to be adopted by the Council.

Crook (Durham).—The Council have decided to light the Hill Top district electrically. Messrs. Pease Partners, from whom the incandescent electric lamps are to be rented, are laying down electricity generating plant.

Croydon.—An agreement has been entered into with the National Electric Wiring Co. for wiring premises in this district on the easy payment system.

Dublin.—The new tramline from Ballybough Bridge through Summer Hill and Great Britain-street to Capel-street and the Northern Quays was opened on Monday.

Digitized by Google

Dudley-Cradley Electric Tramway.—On Friday Col. von Donop officially inspected this line as well as the reconstructed line from Dudley to Sedgley. Electric current for working both lines will be supplied from the Corporation station. The electrical equipment was inspected by Mr. A. P. Trotter six weeks ago, and the cars have commenced running.

Eccles.—There is at present the equivalent of 8,044 8 c.p. lamps connected. The Council have approved the appointment of Mr. H. W. Angus (late chief assistant at Bolton) as borough electrical engineer.

Edinburgh —On the motion of Bailie Mackenzie, convener of the Electric Lighting committee, it was decided on Tuesday to place the balance of the electric lighting account (£3,674. 9s. 4d.) to the credit of reserve.

Election Note.—By the narrowest of minorities Mr. F. Hastings Medhurst, B.Sc., M.I.E.E., was defeated in his attempt to secure for the Unionist party the Radical seat at West Islington, London. Mr. Medhurst's minority was only 19, and there is some talk of a scrutiny.

Electric Traction in Italy.—The steam tramway between Caivano and Naples is to be converted into an electric line.

Erdington.—At the next meeting of the Council the subject of applying for electric tramway powers will be discussed.

Glasgow.—The Tramways committee have decided to promote a bill for power to extend the electric tramways to Clydebank, Bishopbriggs, Rutherglen and Cambuslang, and also along Cumbernauld-road.

Last week permission was granted to the Glasgow Telephone committee to lay underground cables. The master of works reported that cables were to be laid in nearly every street within the district bounded by the river Clyde, Hope-street, George-street, High-street, and Salt-market. He saw no objection to the work being proceeded with except that there would be an enormous interference with the public use of the streets for a considerable time to come. None of the streets could be put into a satisfactory condition for more than 12 months from the time of the first opening. Permission has, however, been granted on the understanding that, with the view of minimising inconvenience to the public, the telephone department carry out, as required by the master of works, the work in streets that may be for other purposes opened up, and that the pavements of streets be, as far as possible, utilised instead of the roadway.

Hospital Lighting.—The Thanet Joint Hospital Board have referred the question of the electric lighting of the building to their Electric Lighting committee.

Leeds.—Application is to be made for sanction to borrow £510,500 for electric lighting and power extensions. At the meeting of the Corporation on Wednesday Ald. Wigram said the Electric Lighting committee had already received permission to apply for sanction to borrow £177,000, regarding which an inquiry had not yet been held. They had also to look to the future demand for electric current throughout the whole of Leeds. The proposed loan included £100,000 for general extensions and £80,000 for extensions on the main road to Wortley, New Wortley, Armley and Bramley, and on to Stanningley. It also covered a scheme for crossing the river again and extending up with the West Hunslet district through Globe-street, that would require at least £80,000. It would also cover £140,000 for development and extension, and the provision of new buildings and of machinery on the site already occupied.

Leicester.—The accounts of the electricity department for the past half year show that the profits, after paying interest, were £1,430, of which £1,068 was handed over to the sinking fund, and £362 to the relief of rates.

Leith.—Application has been made to the Secretary for Scotland for sanction to borrow £20,000 additional for electric lighting extensions. The electric lighting mains are to be extended to Denham Green, and the electrical engineer (Mr. J. G. Scott) has been instructed to prepare plans and estimates of the cost of lighting the whole of the Trinity and Newhaven districts by arc lamps.

Light Railways.—An inquiry was held last week into the application of the Hyde and Dukinfield town councils to construct an electric tramway between Hyde and Dukinfield, and also to connect Stalybridge with the two boroughs. To carry out this scheme the Councils propose to borrow £75,000 each. The tramway would also serve the still wider tramway scheme which is proposed by the Hyde, Dukinfield, Stalybridge and Mossley Councils. For the promoters Mr. Sutton said it could scarcely be said they were competing with the Oldham, Ashton and Hyde electric tramway. The difficulty apprehended in reference to a bridge over the Sheffield and Midland joint line at Hyde could be got over. The consulting engineer (Mr. A. H. Gibbings) gave evidence and said he considered the estimates and proposals reasonable. After hearing Mr. Balfour Browne, Q.C., for the Oldham, Ashton and Hyde Electric Tramway (Ltd.), the Commissioners granted the application in practically its original form.

Carnarvon Council will support the scheme for constructing a light (electric) railway from Carnarvon to Dinas Dinlle.

An inquiry was also held last week into the application of the Wigan and District Tramways Co. to construct a light (electric) railway from Ashton to Pemberton, and after hearing evidence, the chairman of the Light Railway Commissioners (the Earl of Jersey) announced that the order would be granted, subject to the plans being revised and certain protective clauses inserted.

Macclesfield.—A provisional order is to be applied for by the Council.

Maidstone.—Sir William Preece, who was recently appointed to report upon the electric lighting scheme of the Corporation, has visited the town, and his report is generally favourable to the original proposals, but he pronounces against the refuse destructor.

Malton (Yorks.).—Terms have been arranged between the Council and the Northern Counties Electricity Supply Co. by which the latter will apply for a provisional order, and erect electricity works in this district.

Melbourne (Victoria).—A conference of representatives of 11 of the municipalities affected by the Melbourne district electricity supply scheme was recently held at Melbourne to consider the applications and agreements of the Victoria Electric Light, Heat and Power Distributing Corporation, which proposes to supply the whole of the suburban municipalities with electric current for all purposes. Mr. T. Holroyd, secretary and engineer of the promoters, gave an outline of the scheme. Mr. F. G. Wood said he thought the conference should ascertain what guarantees the municipalities would have that the promoters would exploit the concessions if granted. It was pointed out that the corporation would have to obtain an act of Parliament within two years, and would have within the two subsequent years to complete the scheme. Councillor Boyd, of Port Melbourne, had doubts as to the genuineness of the scheme, and expressed the opinion that the Councils should demand a deposit of, say, £50,000 as a guarantee of good faith. The prospectus was drafted "too much on Yankee lines," as the corporation proposed to run the railways, trams, factories, mangles, sewing machines and so forth. If they could do one-tenth of what was proposed he would be satisfied, but the promoters might get the concessions merely to float a company on a large scale in England amongst people who did not understand local conditions, and so make a great profit, and then let the whole thing fall in. Mr. Holroyd explained that the promoters had the assurance of Major Cardew and others that the money could be obtained and the scheme could be carried out provided the concessions were obtained. Eventually it was decided, in view of the fact that the Prahran Council had convened another conference, to remit the whole question to the new conference.

Montrose.—The Lighting committee have engaged Mr. W. W. Lackie, of Glasgow, to report upon an offer received from an electric lighting company to establish electricity works in the district.

Municipal Telephony.—The question of applying for a telephone licence is at present under consideration by the Cheltenham Town Council, and a preliminary report has already been presented by the town clerk (Mr. E. T. Brydges), who has been instructed to approach Mr. A. R. Bennett with a view to preparing a report.

Nelson.—An inquiry was held here last week into the application of the Corporation to borrow £2,500 for electric lighting. The town clerk (Mr. R. M. Prescott) said a provisional order was obtained in 1883. In 1892 borrowing powers to the extent of £10,000 were obtained, and the present loan was needed for additional plant, including extensions to the storage battery. There was no opposition.

Newcastle-under-Lyme.—The Council have decided to advertise for an electrical engineer to report upon the proposed electric lighting scheme.

Paisley.—In response to a numerously-signed requisition, Mr. W. M. Murphy has consented to promote a fresh bill next session for powers to construct a system of tramways for this town and district. The new scheme is to be called the Paisley District Tramways.

Presentation.—On Saturday afternoon (Sept. 29) Mr. John Moore, managing editor of the "Central News," was presented by the indoor staff with a gold watch and chain, suitably inscribed. Reference was made to Mr. Moore's long connection with the Central News Agency, and to the financial success which has resulted from his labours.

Rickmansworth.—After hearing Mr. George Offor, on behalf of the Electrical Power Distribution Co., who are seeking to obtain electric lighting powers for this district, the Council decided to assent to the company's application.

St. Helens.—The borough electrical engineer (Mr. J. S. Highfield) is preparing plans and estimates of cost of carrying out extensions of the electric tramway system.

Salford.—At Wednesday's meeting of the Council a motion was presented by Mr. Makin on the subject of what are called "fair' clauses in contracts. Mr. Makin moved that the Council declare that:—

(a) Contractors tendering for or executing work under this Council must be paying the standard rate of wages to the whole of their workpeople

Digitized by Google

and observing the hours and conditions of labour now recognised by the local organised bodies of workers, and be subject to such alterations as may occur in the various trades, &c. No tender to be accepted from any firm who prohibit their workpeople from joining organised bodies. Any contractor from an outside district whose tender may be accepted shall be required to conform to the rates and conditions of such district.

(*b*) Should the Council have reasonable grounds for believing that the above conditions are not being complied with, the contractor shall be called upon to produce his books to the town clerk for inspection, showing the names of, wages paid to, and the hours of labour observed by all those employed by him.

(*c*) The contractor shall not assign or underlet the contract, or any part of it, or sub-contract, except with the consent of the Council, and upon such conditions as they may think fit; but if the tenderer at the time of tendering states his desire to sublet any portions of the work not usually done by him, the Council will agree to do so with an approved person, the principal contractor being responsible to the Council for the work being done under the same conditions as if done by himself. And should the contractor or agent give or offer any gratuity to any officer of the Council, the Council shall be at liberty to determine the contract. Compliance with this standing order shall be of the essence of every contract, and non-compliance therewith, after notice to the contractor, shall entitle the Corporation absolutely to determine the contract.

The drastic nature of these clauses was recognised, and after some discussion it was decided to leave the subject over for settlement to a special committee to be appointed by the new Council.

Shoreditch (London).—The Vestry have decided to renew the insurance of the electricity and the dust destructor works in the sum of £52,000 at 4s. 6d. per cent.

Stockport.—The Electric Tramways committee have ordered 20 additional tramcars complete, at £675 each.

Tariff Changes.—Under the new customs tariff for British North Borneo railway, telegraph and tramway materials and scientific apparatus and material are admitted free of import duty.

West Bromwich.—It is proposed to supply electric current for private lighting at 6d. per unit for the first hour and 2d. after, and for power at 3d. and 1d. per unit respectively. It has been decided to apply for sanction to borrow £10,000 for the wiring of houses, and also to advertise for a borough electrical engineer at a salary of £250 per annum. (This advertisement appears in another column).

Wigan.—Application has been made to borrow a further £16,500 for electric lighting extensions.

Worcester.—The Electricity committee unanimously reported that it was inexpedient to extend the present generating station, but the proposal to purchase a site for a new generating station in Hylton-road at £3,750 has been postponed.

Workhouse Lighting.—The Poole Guardians are considering the question of lighting the workhouse electrically, and the Bournemouth and Poole Electricity Supply Co. has been asked to submit terms for the supply of current.

York.—In presenting the minutes of the Electric Lighting committee on Monday, the chairman (Ald. Dodsworth) said that during the past six months the electricity department had made a trading profit of over £200. That was very satisfactory, and pointed to even better results in the future.

Marriage.—Mr. Bertram Thomas, proprietor of the Cornbrook Telegraph Works, near Manchester, was married on Thursday last to Miss Ethel Benham, daughter of the late John Benham, of Clapham Park, near London. Mr. Thomas is well known in electrical engineering circles in Manchester, and has been associated with electric lighting and traction work in the Midlands for many years past.

EDUCATIONAL NOTICES.

Electro-Deposition.—At the City and Guilds Technical College, Leonard-street, Finsbury, London, a special course of 10 lessons in practical laboratory instruction in electro-deposition will be given on Wednesday evenings from 7 to 9, commencing Oct. 10. Particulars will be found in an advertisement, and programmes, &c., may be obtained at the College or at the head office of the City and Guilds of London Institute, Gresham College, Basinghall-street, E.C.

Polarisation of Light.—A special course of six lectures on this subject will be delivered by Prof. S. P. Thompson at the City and Guilds Technical College, Leonard-street, Finsbury, London, on Friday evenings from 8 to 9, beginning October 12. Some particulars will be found in an advertisement, and complete programmes can be obtained at the College or at the head office, Gresham College, Basinghall-street, E.C.

"Program" and Calendar.—We have received a programme and calendar of the day and evening classes at the Municipal Technical Institute, West Ham, London, which, following the now general rule, contains some well-executed illustrations of the laboratories, workshops, lecture-rooms, &c., at the institute, showing every indication that the course of technical training, under the able direction of Mr. A. E. Briscoe, B.Sc., Principal of the Institute, has been well designed. The workshops are fully furnished with up-to-date machines and tools, and a prominent feature is the physics and engineering department. The programmes are issued at 1d. each, or post free 3d.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.

The Directors of the *Great Western Railway Co.* invite tenders for various stores for twelve months from Dec. 1st next. Among the articles required are telegraph poles and yellow pine, telegraph instruments and apparatus, copper wire, telegraph ironwork and tools, drysalteries, electric light carbons, incandescent electric lamps, brass work, &c. Samples and patterns may be seen at Swindon from 9th to 18th inst., and specifications may be obtained at the office of the stores superintendent. An advertisement gives further particulars, and tenders addressed to the secretary (Mr. G. K. Mills), Paddington Station, London, W., must be in by 22nd inst.

By command of the *Postmaster-General* tenders are invited for red fir telegraph poles and for creosoting. These tenders will be received until 10 a.m. of Monday, 22nd inst. Further particulars will be found in an advertisement, and forms of tenders may be obtained of Mr. Chas. E. Stuart, controller of stores, General Post Office, London.

Whitechapel (London) Electrical committee require tenders for a hand-driven overhead travelling crane for their electricity station. Specifications may be obtained at the electricity works, 27, Osborn-street, E., and tenders (addressed to chairman) must be delivered by noon of 23rd inst. An advertisement gives further particulars.

Glasgow Corporation invite tenders for cables for connecting up plant and transformer connecting bars for the Pinkston power station. Specifications from general manager of tramways department (Mr. John Young), 88, Renfield-street, Glasgow, and tenders to town clerk (Sir J. D. Marwick) before 1 p.m. Oct. 13. An advertisement contains some further particulars.

Glasgow Corporation also require steel straight track and curved rails and fish-plates. Tenders by 23rd inst.

The Streets committee of the *City of London* Corporation are again advertising for a mechanically-driven dust cart. Further information can be obtained from the electrical engineer (Mr. A. A. Voysey), Public Health Department, Guildhall, E.C. Tenders addressed to the town clerk (Sir J. B. Monckton), must be in before Nov. 10. See advertisement.

Cardiff County Borough invites tenders for slow-speed vertical engines, slow-speed converters, and boilers and economisers, &c. Specifications can be obtained from the tramways engineer (Mr. Arthur Ellis), Old Post Office-buildings, Cardiff, and tenders must be sent to Mr. J. L. Wheatley, town clerk, Town Hall, Cardiff, by 23rd inst. An advertisement gives further particulars.

The directors of the *Lancashire and Yorkshire Railway* invite tenders for supply of stores during the 12 months ending Oct. 31, 1901. Among the articles required are brake blocks, copper, india-rubber, castings, ironmongery, sundry tools, &c. Tenders to secretary (Mr. R. C. Irwin), Hunt's Bank, Manchester, by 10 a.m. Oct. 8.

The *Secretary of State for India* invites tenders for (1) a complete electrical installation for supplying power to a factory from a waterfall 3 miles distant, and (2) a complete hydraulic installation to develop about 500 H.P. Tenders to India Office, Whitehall, S.W., by 2 p.m. Oct. 16.

Bermondsey (London) Vestry invite tenders for steam, feed exhaust, and drain pipes, feed pumps, water storage tank and sundry ironwork, and also for steam dynamos, battery charging motor, booster, and balancer. Tenders to vestry clerk by Oct. 15.

Swansea Corporation invite tenders for cast-iron arc and incandescent lamp standards. Tenders to Messrs. Kincaid, Waller and Manville, 29, Great George-street, London, S.W., before noon Oct. 10.

Sunderland Corporation invite tenders for the supply of 24 car bodies, trucks, and electrical equipment. Tenders to chairman Tramways committee by noon Oct. 15.

Bootle Corporation invite tenders for a steam dynamo. An advertisement gives further particulars. Tenders to chairman Electric Traction and Lighting committee before Oct. 13.

Digitized by Google

Aberdeen Town Council invite offers for 25 electrical tramcars, and for equipments for six horse cars about to be converted. Tenders before noon of Oct. 17.

Bradford Corporation require tenders for an engine and dynamo, switchboard apparatus, &c., for their destructor works. Tenders to town clerk before Oct. 9.

Ilford District Council invite tenders for direct-current meters and cutouts. Tenders to clerk by noon Oct. 8.

Nottingham Council invite tenders for 1,500 tons steel girder tram rails and 76 tons fishplates. Tenders to town clerk before Oct. 8.

Maidstone Corporation invite tenders for surface condenser and feed pumps. Tenders to town clerk before 10 a.m. Oct. 16.

Ayr Corporation invite tenders for tramway rails and fish-plates. Tenders by 12th inst.

Dartford Council invite tenders for the erection of electricity station buildings. Tenders by 20th inst.

Tenders are invited for re-wiring the abattoir premises, *Brighton*. Tenders to town clerk by Oct. 11.

Tenders are invited until Nov. 2 by the municipality of *Piatra Neamtz* (Roumania) for the electric lighting of the town for 30 years.

Tenders are invited by the *Stavanger* (Norway) Corporation for erecting plant for the transmission of power from the Altesrig Waterfalls to Stavanger, a distance of about 39 kilometres. Tenders by Jan. 2. Further information from the British Vice-Consul at Stavanger (Mr. E. Berentsen).

It is announced that tenders will be received up to Nov. 8 (not Oct. 13, as erroneously given last week) by the municipality of *Velez Blanco*, Spain, for the concession for lighting the town by electricity for 20 years.

Tenders will be received up to Nov. 27 for a tramway concession for *Zaragoza*, Spain. Particulars of the conditions were published in the *Madrid Gazette* of Sept. 27.

TENDERS RECEIVED AND ACCEPTED.

Worthing Town Council have received the following tenders for the supply of electricity generating plant :—

Contract No. 1.—Steam Dynamos.

Ernest Scott & Mountain (*accepted*)	£2,850 0	Westminster Eng. Co.	£3,520 0
Brush Co.	4,500 0	Ditto	3,176 0
Ditto	3,600 0	J. H. Holmes & Co.	3,500 0
Siemens Bros. & Co.	4,063 0	Ditto	3,400 0
Ditto	3,895 0	Ditto	3,300 0
Ditto	3,821 0	Ditto	3,000 0
E.C.C. Co.	3,956 0	British Westinghouse Co.	3,490 0
Ditto	3,614 0	Ditto	3,310 0
Ditto	3,432 0	Mather and Platt	3,475 0
Laurence, Scott and Co.	3,800 0	Ditto	3,415 0
Ditto	3,459 0	Ditto	3,100 0
Ditto	3,285 0	Rosling, Appleby & Fynn	3,466 0
Ditto	3,205 0	British Schuckert Co.	3,422 0
Ditto	3,203 0	Ditto	3,190 0
Ditto	2,952 0	Ditto	3,158 0
Ditto	2,932 0	Electrical Co.	3,420 0
P. R. Jackson & Co.	3,730 0	Ditto	3,230 0
Ditto	3,590 0	Ditto	3,225 0
Ditto	3,470 0	General Electric Co.	3,408 0
Thos. Parker (Ltd.)	3,669 0	Ditto	2,890 0
Ditto	3,488 0	W. H. Allen, Son & Co.	3,371 0
Ditto	3,270 0	Lancashire Dynamo and Motor Co.	3,332 0
Clarke, Chapman & Co.	3,664 0	Ditto	3,230 0
D. Bruce Peebles & Co.	3,654 0	Ditto	3,102 0
Ditto	3,490 0	Ditto	3,054 0
Ditto	3,405 0	Thames Ironworks, Shipbuilding and Eng. Co.	3,257 0
Ditto	3,402 0	Ditto	3,181 0
D. Selby Bigge & Co.	3,650 0	Ditto	2,750 0
Johnson and Phillips	3,640 0	Dudgeon & Co.	2,995 0
Ditto	3,110 0	Reavell & Co.	2,868 0
Ditto	3,090 0	Ditto	2,772 0
Crompton & Co.	3,633 0	Mavor and Coulson	2,836 15
Ditto	3,487 0	C. A. Parsons & Co.	2,818 0
Ditto	3,225 0		

Contract No. 2.—Boilers, &c.

E. Danks & Co. (*accepted*)	£1,130	Fraser and Fraser	£1,627
Tinkers Limited	1,975	Taylor & Sons	1,580
John Fraser & Son	1,900	Davey, Paxman & Co.	1,500
Ditto	1,330		

Contract No. 3.—Steam Pipes, Condensing Plant, &c.

Blackwell & Co. (*accepted*)	£1,731 15	Babcock and Wilcox	£2,252 0
Rosser and Russell	2,756 10	J. Spencer & Co.	2,247 0
Crompton & Co.	2,627 0	Aiton & Co.	2,209 0

Contract No. 4.—Manhole Covers.

Callender's Co. (*accepted*)	£501 3 0	Mackenzie Bros.	£573 15 0
Western Electric Co.	951 10 0	Watson, Gow & Co.	521 7 6
Haley & Co.	586 19 0	Bird & Co.	475 16 6

Contract No. 5.—Arc Lamp Posts.

Mackenzie & Co. (*accepted*)	£1,353 5	Allan (Sen.) & Son	£1,874 4
General Electric Co.	2,347 15	McDowall, Steven & Co.	1,786 0
Haley & Co.	2,075 10	Rowland Carr & Co.	1,631 9
Crompton & Co.	2,010 5	J. Kershaw	1,622 0
Western Electric Co.	1,952 0	Bradley	1,585 0
W. Lucy & Co.	1,883 0	J. and A. Law	1,567 0

Contract No. 6.—Stoneware Casings.

Albion Clay Co. (*accepted*)	£2,102 3 6	Western Electric Co.	£2,298 0 0
		Doulton & Co.	2,102 3 6

Contract No. 7.—Cablework.

Callender's Co. (*accepted*)	£5,967 15 3	Western Electric Co.	£5,406 10 5
Telegraph M'fg. Co.	9,093 4 3	W. T. Henley's Telegraph Works Co.	6,189 2 2
W. T. Glover & Co.	7,059 0 0	Brit. Insulated Wire Co.	6,156 14 10
Siemens Bros. & Co.	6,991 8 8	St. Helen's Cable Co.	5,870 0 0

**Contract No. 8.—Arc Lamps.*

Johnson and Phillips	£1,324 0 0	General Electric Co.	£1,140 0 0
Western Electric Co.	1,324 0 0	Gilbert Arc Lamp Co.	951 5 0
Crompton & Co.	1,166 0 0	Oliver & Co.	850 17 0
Westminster Eng. Co.	1,149 0 0	British Schuckert Co.	765 0 0
Brockie-Pell Arc Lamp	1,143 16 8	Electrical Co.	693 0 0

*Contract No. 8 has not yet been let.

Contract No. 9.—Storage Batteries.

Eclipse Brass and Copper Co. (*accepted*)	£984 4	E.P.S. Co.	£1,973 0
Chloride Elec. Storage Synd.	2,145 0	Tudor Accumulator Co.	1,860 0
		Hart Accumulator Co.	1,535 0
		D.P. Battery Co.	1,386 0

Contract No. 11.—Boosters, &c.

Laurence, Scott & Co. (*accepted*)	£710 0	Rosling, Appleby & Fynn	£980 0
Siemens Bros. & Co.	1,469 0	British Schuckert Co.	976 0
Thos. Parker (Ltd.)	1,047 0	Brush Co.	959 0
J. H. Holmes & Co.	1,040 0	Thames Ironworks Co.	955 0
Crompton & Co.	1,177 0	Mavor and Coulson	912 15
British Westinghouse Co.	1,016 0	Lancs. Dynamo & Motor Co.	838 0
D. Bruce Peebles & Co.	995 0	General Electric Co.	850 0
Electrical Co.	982 0	Dudgeon & Co.	543 10

Contract No. 12.—Economiser.

A. Lowcock (Ltd.) (*accepted*)	£372 10	Roberts Bros.	£390 0
Green & Co.	390 10	Carter & Son	385 0

Contract No. 13.—Travelling Crane.

Carrick & Ritchie (*accepted*)	£165 0	Larmuth & Co.	£230 0
Whitley & Co.	371 0	Pickerings (Ltd.)	229 15
Measures & Co.	300 0	J. Carrick & Son	211 0
Southgate Engineering Co.	244 10	Higginbottom & Mannock	176 0
J. Spencer & Co.	235 0	Chatteris Engineering Co.	157 0

Hull Corporation have received the following tenders for the supply of steam and water pipes, feed pump, water softener, &c., for their Sculcoates-lane generating station :—

Barker & Aspey (*accepted*)	£1,627 0 0	Tyndall, Earle, and Hutchinson	£1,910 3 9
Rose, Downs & Thompson	2,319 0 0		
Aiton & Co.	1,853 0 0		

Water Softener Only.

Lawrence Co.	£520 0	Mather & Platt	£225 10
Desrumeaux & Co.	465 0	Doulton & Co.	225 10

Grays (Essex) Council have accepted the following tenders for the supply of electricity generating plant :—

Callender's Co. (cables)	£3,454 0 0
E. Danks & Co. (boilers)	2,325 0 0
British Schuckert Co. (steam dynamos)	2,147 10 0
D.P. Battery Co. (storage battery)	836 1 0
General Electric Co. (switchboards)	628 15 0
E. Green & Son (economiser)	241 10 0
Carrick and Ritchie (crane)	96 10 0

Tenders have also been let for the erection of electricity station buildings at £4,174, and for roadwork, &c., at £1,005. 14s. The total of the accepted tenders is about £15,000.

Bradford Corporation have accepted the tender of the Lorrain Steel Co. (U.S.A.) for the supply of 2,000 tons of tramway rails at £7 per ton, with the necessary fish-plates at £8 per ton, subject to such conditions as may be specified by the borough engineer. Ald. Smith, at the Council meeting on Wednesday, wanted to know why the Tramways committee had gone to America for their rails, and the chairman of the committee (Ald. M. Booth) replied that they were £1 per ton cheaper than English rails.

Eleven tenders, varying in amount from £130 to £412, were received for wiring and supplying electric lighting fittings for the new Connaught Drill Hall, Portsmouth, now being erected for the 3rd V.B. Hants Regiment. The lowest tender, that of Messrs. Pyke, Harris & Co., was accepted.

The tender of the Hart Accumulator Co. has been accepted for the supply of the storage battery required for the electric lighting of the Cotsworth Sanatorium.

Digitized by Google

The tender of Messrs. Dick, Kerr & Co. has been accepted by Dundee Council for the supply of a water cart, sweeper and rail cleaner for the electric tramways at £795.

Barrow-in-Furness Corporation have accepted the tender of Messrs D. Bruce Peebles & Co. for one year's supply of electric motors. (1 H.P. to 10 H.P.) for hiring-out.

Glasgow Tramways committee have accepted the tender of Messrs. Babcock and Wilcox for steam piping, &c., for Pinkston power station at £21,051.

Newcastle-upon-Tyne Tramways committee have accepted the tender of the National Construction Co. for the supply of conduits.

APPOINTMENTS VACANT AND FILLED.

West Bromwich Corporation invite applications for the post of borough electrical engineer. Commencing salary, £250 per annum. An advertisement contains further particulars, and applications must be sent in to Mr. Alfred Caddick, Town Hall, West Bromwich, by 17th inst.

Poplar (London) District Board of Works require an accountant and chief clerk for their electricity department. An advertisement gives further particulars, and applications must be lodged with the clerk (Mr. Leonard Potts), 117, High-street, Poplar, London, E., by 12th inst.

West Hartlepool Corporation require two assistant engineers for their electricity department. Applications to borough electrical engineer (Mr. H. F. Friederichs), by Oct. 13. See advertisement.

The Southampton Corporation require a mains superintendent. Applications to the town clerk (Mr. R. R. Linthorne), Municipal Offices, Southampton, by 12th inst. See advertisement.

There is a vacancy for a shift engineer at the Blackpool electricity works. Applications to chief engineer and manager (Mr. A. S. Giles) by Oct. 11. See advertisement.

Islington (London) Vestry require a draughtsman, an engine driver and also stokers for their electricity department. Applications to the vestry clerk (Mr. W. F. Dewey), Vestry Hall, Upper-street, London, N., by Oct. 8. See advertisements.

Belfast Corporation require a principal for their proposed technical institution. Salary £600 per annum. Applications by 22nd inst.

An assistant master for physics and chemistry is required in the secondary school, Rutherford College, Newcastle-on-Tyne. Applications by 12th inst.

An assistant science master is required for physics and chemistry for the High School, Newcastle-under-Lyme. Applications to head master.

Mr. Wm. Stevenson has been appointed telegraph superintendent and electrical engineer of the Caledonian Railway Co. in succession to Mr. A. S. Dunn, who recently resigned. Mr. Stevenson has been assistant to Mr. Dunn for many years.

Mr. J. W. A. Binner, of the Blackburn electricity works, has been appointed chief assistant engineer at Accrington.

BUSINESS NOTICES.

Prof. Alex. B. W. Kennedy informs us that in future the style of his firm will be Kennedy and Jenkin, and all communications should be addressed in this manner.

Mr. J. Wemyss Anderson has entered into partnership with Mr. Alfred Hay, B.Sc., M.I.E.E., and the firm will carry on business as consulting electrical engineers at Pearl Assurance Buildings, Liverpool.

Mr. Robert Green has arranged to take over the interest of his late partner (Mr. Edward Pritchard) in the firm of Pritchard & Co., consulting engineers, Birmingham, and in future practice will be carried on under the style of Pritchard, Green & Co.

The London offices of the Lilleshall Company have been removed to 71, Finsbury-pavement, E.C. Telephone 1,691 London Wall.

BANKRUPTCIES, LIQUIDATIONS, &c.

At the Burnley Bankruptcy Court last week the public examination took place of Robert Foster and Walter Baker, electrical engineers, &c., trading as Robert Foster & Co. at Burnley, and also as the Nelson Electrical Engineering Co. at Nelson. The bankrupt Foster said he commenced business in 1895 with £30 borrowed capital. He entered into partnership with Baker in Jan., 1899. Between 1895 and Baker coming into the business he had been making a profit. Baker brought about £350 into the business. Witness had put about £1,000 into the business since 1895, obtained from his father and brother, and none of it had been repaid. All the money went into the business, £500 of it after Baker came into partnership. He first discovered that he was insolvent in January. It was not a fact that his business was insolvent before the partnership. The reason it did not pay after the partnership was that they extended the business and sold goods at too little profit. Foster was cross-examined at some length, and eventually the examination was adjourned. Baker was not examined, his examination being also adjourned until the next court.

T. W. Greaves and W. G. Randall (trading as T. W. Greaves & Co.), electrical engineers, 230, East India Dock-road, and 6, Nelson-street, Greenwich, London, have been adjudicated bankrupt.

A first and final dividend of 2s. 8½d. is payable in the bankruptcy of B. Symmons (trading as B. Symmons & Co.), electrical engineer, 2, North-street, Quadrant, Brighton, and 15, Holland-road, Hove.

On Sept. 24 it was resolved to wind up voluntarily the St. Stephen's Electrical Syndicate (Ltd.). Mr. A. N. Tessier, 1, Arthur-street, King William-street, London, E.C., is liquidator.

Claims against the Roller Bearings Co. (Ltd.), in liquidation, must be sent by Nov. 9. Mr. F. L. Fisher, Portland House, Basinghall-street, London, E.C., is liquidator.

Telegraph Stores Sale.—The Postmaster-General invites tenders for the purchase of old stores, including about 40 tons of gutta percha, 90 tons of copper wire, plates, &c., indiarubber covered copper wire, tools, &c. An advertisement contains further particulars, and tenders, on forms to be obtained from the Controller of Stores (Mr. Chas. E. Stuart), G.P.O., West, London, E.C., must be in by 10 a.m. 18th inst.

Plant for Sale.—Leeds Corporation invite tenders for the purchase of plant at present in use in connection with their system of electric tramways. Further particulars are set out in an advertisement. The plant, which is in excellent condition, can be inspected on application to the engineer-in-charge at the Corporation generating station. The consulting engineers (Messrs. Hopkinsons and Talbot), 26, Victoria-street, London, S.W., will supply additional information; and tenders (addressed to Tramways Committee) should be sent to town clerk's office, Town Hall, Leeds.

Messrs. Wheatley Kirk, Price & Co., 49, Queen Victoria-street, London, E.C., and Albert-chambers, Manchester, have for disposal a quantity of electrical plant in excellent condition. An advertisement contains further particulars.

Oldham Electric Light committee invite tenders for two 40kw. shunt-wound dynamos and a spare armature, which will be for disposal in December next. An advertisement gives further particulars, and offers must be sent to the superintendent (Mr. Arthur Andrew), Gas and Water Offices, Oldham.

To Let.—An advertisement contains particulars of a water-power-driven flour and grist mill situate at Lindfield, Hayward's Heath, Sussex, which is to be let. The mill is suitable for electrical or mechanical engineering works. Applications to Mr. J. G. Marshall, consulting engineer, Norwich Union-chambers, Birmingham, or to Messrs. F. Morrell & Sons, solicitors, Oxford.

Fire.—A fire broke out on Tuesday morning at the works of Messrs. Stephens, Smith & Co. (Ltd.), electrical and marine engineers, Millwall. The premises were severely damaged by fire, the cause of which has not been ascertained. The contents and building were insured.

Arc Lamp Coupling.—Mr. G. Braulik, 217-218, Upper Thames-street, London, issues a circular illustrating and describing his patent coupling for arc lamps, which he claims to be specially adapted for high tension. The coupling consists of two contact covers—one fixed and one movable. The springs are so arranged that all the parts are fixed on the lower plug, and can be readily examined when the carbons are being renewed or the lamp cleaned. All the current-carrying parts are securely mounted and highly insulated with porcelain and protected from the weather by a solid cap. When the lamp is lowered current is switched out by double poles. A special base plate for use with these couplings is also illustrated.

Telephones and Telephone Apparatus, &c.—Messrs. L. M. Ericsson & Co, of Temple-chambers, Temple-avenue, London, E.C., and Stockholm, send a copy of their latest catalogue of telephones and telephone apparatus, in which is illustrated and described every requisite for public and private telephone installations. The catalogue is in three languages—English, German and French, and is well executed. Prominence is given to a number of instruments of which large quantities are in use in this country and on the Continent. The illustrations include a fine view of the interior of the Copenhagen telephone exchange for 10,000 subscribers, equipped by Messrs. Ericsson & Co., and of the Stockholm exchange for 7,000 subscribers, erected as far back as 1886. Sections of the catalogue deal with telegraphic apparatus, testing instruments and electric fire alarms.

Paris Exhibition Award.—Messrs. W. A. S. Benson & Co., art metal workers and electrical engineers, New Bond-street, London, have received the only gold medal awarded to the British section at

Digitized by Google

the Paris Exhibition for electric lighting and fittings. This firm make a speciality of electrical work, and are responsible for the installations at Cambridge University and St. Paul's Cathedral, to mention two only out of many. The handsome fittings in the British National Pavilion at Paris were mainly lent by Messrs. Benson & Co.

Mather and Platt Plant.—A revised list of steel-clad motors and accessories is issued by Messrs. Mather and Platt, and can be obtained on application.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Sept. 26 to Oct. 2, with the ports of destination :—

Africa.—Cape Town, £158; Durban, £271; East London, £15; Port Elizabeth, £22; Port Said, £8. *Argentina*—Buenos Ayres, £924 (including £799 telegraph material); Rosario, £219. *Australasia*—Auckland, £20; Brisbane, £178 (telegraph cable); Fremantle, £164; Melbourne, £162; Port Chalmers, £38; Sydney, £1,477. *Belgium*—Ostend, £154. *Brazil*—Rio Janeiro, £142. *Chili*—Valparaiso, £414 (including £344 telegraph wire). *Cochin China*—Saigon, £20. *Denmark*—Copenhagen, £379 (telegraph wire). *France*—Calais, £52. *Germany*—Hamburg, £606 (including £200 telegraph material). *Gibraltar*, £650 telegraph apparatus). *Holland*—Amsterdam, £30; Rotterdam, £44 (including £28 telegraph material). *India*—Calcutta, £57. *Malta*, £308 (including £152 telegraph material). *Portugal*—Lisbon, £50. *Russia*—St. Petersburg, £54. *Spain*—Grenada, £28 (telegraph material). *Straits Settlements*—Singapore, £50,054 (including £50,000 telegraph cable). *Sweden*—Stockholm, £510 (telegraph material). *Uruguay*—Monte Video, £46. Total £57,254, against £14,896 in the corresponding week last year (Sept. 27 to Oct. 3).

COMPANIES' MEETINGS AND REPORTS.

Willans and Robinson (Ltd.).

The ordinary general meeting of this company was held at the Victoria Works, Rugby, on Wednesday, under the presidency of Mr. MARK ROBINSON, M.Inst.C.E.

The SECRETARY (Mr. C. S. Essex) having read the notice convening the meeting,

The CHAIRMAN said: Ladies and gentlemen, in proposing the adoption of the report and accounts, there is one feature only which is unpleasant, and which is so new and so marked that we have thought it right to mention it in the report—namely, the very large sum locked up in what is known in the accounts as "Work in Progress," though it really includes all work, whether finished or not, which we have not been able to send away by the end of the half-year, and to invoice. Over £61,000 of the whole sum shown represents engines, all of which were on order, and a very large number of which were finished at the end of the half-year, though for reasons beyond our control we were not in a position to send them away to the buyers. The activity of the electrical trade has led to some of the dynamo makers getting greatly behind with their orders, and as we have hitherto managed, by the aid of our late extensions, to keep up with our work better than was previously the case, the engines have gone ahead of the dynamos, and have to be kept waiting here until the latter are ready. Of course, there are also cases where engines wait for some fault of ours. From the one cause or the other there is always a large sum locked up in the form of work in progress, but this time it has risen beyond all precedent. Understand that this is no question of safety of our funds, only of unprofitable employment. The engines are in our hands, and they are on order from people who represent largely the most sound and solvent, though perhaps not always the most considerate, class of customers—the municipal corporations and electric light companies, or else the important electrical firms who in many cases stand as over-contractors between us and the buyer. That so much money is locked up through the delays of other people gives us, of course, ground for complaint against them, and it may perhaps be asked whether it does not justify a demand for compensation. If so, I can only answer that there must be give and take in business. There were days when we were behindhand with engines and when we kept the dynamo people waiting for their money, and we remember that they treated us then with forbearance. How we should deal with such cases must depend upon considerations of general policy, and I am sure you will be glad to leave this in the hands of the directors. The present great lock-up from this cause has every appearance of being temporary, but it is incontestable that such matters grow rapidly in a business like ours, and that we must reckon upon a large part of our capital being more or less permanently locked up in a form not directly productive. It is an incident of our class of business, and if the business continues profitable I think we shall have to allow not only that it is a necessary incident, but that it is one of the conditions which enable us to work the remainder of the capital to advantage. It will be noticed that the half-year's net profit is slightly decreased, but it has often been pointed out that half-yearly periods are too short to give anything like fair average results. In this case the profit locked up in finished engines far more than accounts for the difference. You see we are still able to carry forward an increased balance. The new issue of shares was in all respects successful. We took much pains to do justice among those who applied for the small balance not taken up by the original allottees; but, as usual, I am afraid the disproportion between the number of shares and the number of applicants leaves us no hope that the latter were satisfied. The large engine working at the Paris Exhibition has been a great success. It is the first engine of its size—namely, 2,400 I.H.P. as normal maximum load and 3,000 I.H.P. as "emergency load," or just twice the power of the previous "large" engine, of which we have made so many for various lighting stations. It is gratifying that Messrs. Siemens Bros. (Ltd.) received a Grand Prix for their fine dynamo, as we did for the Willans engine. We think the experience gained, to say nothing of the credit, will be extremely useful to us, and I may say at once that it has altered my views, and I think those of my colleagues, as to the supposed limitations upon the profitable increase of size in Willans engines. We are prepared now to take orders for Willans engines of any size, though still ready, for large powers, to make other patterns as well. It is a fortunate thing that an international exhibition of this magnitude has been held at the very time of our new departure in the construction of very large engines, so that the first of them has been thus admirably introduced to the public. Perhaps the greatest use to us of the Paris Exhibition has been the introduction of the engine to English engineers and electricians, and to English municipal authorities, all of whom have visited the exhibition, and from whom we have heard many gratifying things. Two other engines of the same size are on order for a British lighting station, and good progress has been made with them. Under the circumstances we have felt justified in recommending that the cost of carrying out this important exhibit at Paris should come out of the money we have received as premiums on shares. It is an expenditure made once for all, because this kind of demonstration need not be repeated, at least on anything like the same scale; and, further, its object is to facilitate the work which the new capital was expressly subscribed to effect—viz., the opening of a trade in engines of large power. Those expenses exceeded £2,000 in June last, and when the engine is brought home again they will certainly have exceeded £3,000. We also propose to debit the premiums account with the cost of removal from Thames Ditton and with the depreciation of the plant and property there. We propose in these two ways to apply about £5,000 out of the total balance of £44,656. 2s. which, either in hand or to come, now remains unappropriated of a total of £92,500 received for premiums on issues of capital. The remainder, £39,656, will be carried to the reserve fund. We trust these arrangements, which have been the subject of much consideration, may meet with your full approval. When I last addressed you our new boiler works near Chester had faded almost into the clouds, for the very site was then uncertain. The validity of the lease (through no fault either of the landlord or ourselves) was impugned, and tedious, though not costly, law proceedings lay before us, before we could again call the site our own. Well, it is ours at last, and we have made the most of the time which elapsed since we secured it. The new works, the sidings, and the pier on the river Dee, all make good progress. But we must be under no delusions as to the time we shall have to wait for the more important and heavier articles of plant on order. These will keep back the starting of actual work for a great many months, probably until some time after the buildings are finished. Meanwhile, our satisfaction with the boiler itself, and our belief in its future, continue to increase, and though marine work is not our main object, the shareholders will doubtless have seen with pleasure the announcement that the Admiralty intends to fit the Niclausse boiler not only in another small vessel, but also in one of the new first-class cruizers, carrying 22,000 H.P. Six months ago I said that the starting of the boiler works must result in still larger necessities in the way of capital, beyond what we have lately issued. The truth of this is increasingly evident, for we have before us now not only the future exigencies of the boiler business, but the very present fact of the greatly increased cost of all building operations, especially those involving the use of much constructional steel work. We are suffering much from this cause at Chester, and equally so in the large extensions we are making in the shops at Rugby. Beyond all these causes of increased expenditure is the constant and apparently inevitable increase in the lock-up which I have dealt with in the beginning of my speech. We shall be able to speak more definitely in the spring upon this subject. We propose to carry the usual amount to the reserve, and it may be pointed out that before the summer of next year the reserve fund may probably be brought up to £100,000, or the full amount of the debenture debt, irrespective of about £19,000 which will then stand in the debenture sinking fund. While the general body of our shareholders has certainly applauded the rapid building up of this magnificent reserve, there are some who have disapproved, and we think it might well be considered whether we need continue to add more to the reserve fund when it has reached £100,000. Many shareholders would like to see the goodwill written down. Personally, my view is that our goodwill is worth enormously more than it stands at in the accounts; the history of the company proves this. Nevertheless it will be prudent finance, when we have put by so much against a rainy day, if we turn our attention to the goodwill. Profit reserved for that purpose, it will be noticed, is not required to be invested, as that put to the reserve ought to be; it remains in the business, and earns dividend, though it takes none. We therefore suggest, for further consideration at a later meeting, that when the reserve fund reaches £100,000, we leave it at that, at least, for a time, and turn our attention to writing down the goodwill. Gentlemen, I beg to move—

"*That the report and accounts for the half-year ended June 30, 1900, submitted to this meeting be and the same are received and adopted.*"

Capt. BECKFORD seconded the motion.

Mr. G. W. ANDERSON contended that the share premium account was an account of capital received and that the reserve account should be reserve of profits on the business, which were kept for the equalisation of dividends and other purposes. He therefore moved that the expenses

Digitized by Google

incurred at the Paris Exhibition should be placed to a suspense account, and written off from the profits by instalments, so that the expenses might not fall unduly in any one half-year.

Mr. J. C. PEACHE seconded the proposal. He contended that the engine shown at the Paris Exhibition was simply by way of advertisement, and that it was as much chargeable against profit and loss as the advertisements that were put down in that account.

The DEPUTY CHAIRMAN (Sir Gilbert A. Clayton East, Bart.) said it was quite right for Mr. Anderson to raise the question whether premiums were capital. He did not consider they were, but his opinion or a shareholder's opinion was of no value. The moment the question was started, it was a legal one, and it was quite right to refer it to a solicitor to deal with. He believed that in the case of all companies established of late, the premiums had been devoted to reserve. The auditors had agreed to what the directors proposed.

The CHAIRMAN held that premiums on shares were not capital in any sense of the word. It would be a foolish thing to do, but legally he thought the shareholders had power to divide the premiums among themselves. In answer to Mr. Anderson, he would say that the original patent for the Niclausse boiler had about nine years to run, but there were plenty of patents even up to the present year. They arranged to write off the sum paid for the original patent within the term of its life. With that exception they had never put anything down for patents. He believed that the company would go on just as well without patents as with them.

Mr. LAZENBY said he considered that premiums were a realisation of the improved position of the company, and that they were therefore in the nature of a deferred profit.

The report and accounts were then adopted unanimously, and the payment of a dividend for the half-year ended June 30 last at the rate of 6 per cent. per annum on the preference shares and at the rate of 10 per cent. per annum on the ordinary shares was approved.

A cordial vote of thanks to the chairman and directors terminated the proceedings.

Typewriting Telegraph Corporation (Ltd.).

The first ordinary general meeting of this corporation was held yesterday (Thursday), the Right Hon. Sir JAMES FERGUSSON, Bart., M.P., presiding.

The SECRETARY (Mr. J. Sampson) read the notice calling the meeting.

The CHAIRMAN said that was the first or statutory meeting since the incorporation of the company, and the financial position was that 26,800 shares had been taken up and allotted, making available £15,000 clear for the development of the business of the company. That would be quite sufficient because they did not require a great deal of capital to carry on the business, as the General Post Office and the National Telephone Co. were very large customers with them, and paid for the instruments as they acquired them. Negotiations were in progress for the sale of certain of the patent rights, including those for America, Germany, South Africa, France, and Scandinavia, the profit in respect to which would come entirely to this company, because they had acquired the whole of the patent rights. Inquiries were being received for installations which would be fitted as fast as the instruments could be supplied. Contracts with the General Post Office and the National Telephone Co. were being completed, and would in all probability be sealed almost immediately. Perhaps the shareholders were aware that the General Post Office and the National Telephone Co. had for a considerable time been taking the instruments and supplying them for private wires, and the company would inherit that business. This invention was particularly suitable for private wires, as it required no technical experts to work it. It was also of great value in large engineering and other important works, also in exchanges for the distribution of parliamentary, racing, cricket and other telegraphic news, which could be done far more cheaply by this method than by that now in use. It was also specially useful in military operations, because the instrument was of a very portable nature, and by a very simple arrangement the messages sent could be kept absolutely secret. The wires were not able to be tapped and the message, instead of being delivered in cipher, was in plain printing. He felt confident as to the success of the extremely clever invention which the company possessed, and referred to the fact that he had been approached to take the position of chairman, he being a director of the National Telephone Co., which was one of their chief customers.

In reply to a question, the CHAIRMAN said the total number of shares issued was 71,000, leaving a balance unallotted of 29,000.

Mr. CROUCH said that he presumed, therefore, that they would have to pay dividend upon that 71,000 shares, and he would like to know whether it was contemplated to begin to do so soon.

The CHAIRMAN said not before the expiry of six months.

Mr. GIBSON asked if the chairman was aware there was a rival instrument on the market, and whether it was likely to damage the prospects of this company.

The CHAIRMAN said that he had seen the rival instrument, and it was a very ingenious invention. He was exceedingly amused with it. It had not been tested over very long distances, he believed. It was claimed for it that it reproduced the sender's handwriting, which was perfectly true, whereas their own company claimed as a greater merit that it reproduced a clearly typewriten message. He supposed there always would be rivals in the field.

Mr. W. M. MORDEY (consulting engineer to the company) gave a technical description of the machine, and pointed out that it could be used in conjunction with the telephone, and said that should the intended recipient of a message be absent he would find upon his return to his office the message clearly typewritten. Used in conjunction with the telephone it had the advantage of setting down in typewriting the essentials of telephone messages, and, moreover, an additional advantage was that messages in foreign languages, which perhaps could not be translated by a clerk in the office, were placed on record in plain writing.

No resolution was submitted to the meeting beyond a vote of thanks to the chairman, which was carried unanimously, and the proceedings terminated.

HAWAIIAN TRAMWAYS CO. (LTD.)—At a recent meeting, the chairman (Col. C. M. Davidson) said the question of the adoption of electric traction had had careful consideration, but progress had been checked by a rival company in Honolulu, and that this opposition had resulted in litigation. Everything requisite to equip and work a mile of road electrically was in hand and had been paid for; and the directors were anxious to make a start as soon as this could be legally done. The company would have to generate their own current. They had been anxious to use water power, as it would be much cheaper, but this could not be arranged, and they would have to employ steam power.

NEWCASTLE-UPON-TYNE ELECTRIC SUPPLY CO. (LTD.)—An extraordinary general meeting of this company was held yesterday (Thursday) at Newcastle-on-Tyne, when a special circular issued by the directors was read. Reference was made to the bills promoted by the company in Parliament this session for powers to supply electric current outside the area defined by the original provisional order, and also to the provisional order which has been obtained for the supply of electric current to Gosforth. The circular continues: The acquisition of these extended powers entails upon the company the obligation of taking immediate steps for generating and supplying electricity in the whole of the area for which they have powers. As soon as plans are matured the directors intend to propose to invite applications first from the shareholders and then, if necessary, from the public, for the additional capital required for carrying out this programme. Sir Lindsay Wood, Bart., and Mr. John H. B. Noble have been elected additional directors of the company.

RECORDING TELEGRAPHS (LTD.)—An extraordinary general meeting of this company was held on Tuesday, Mr. J. A. Sillars presiding. Mr. Sillars said they had to consider a resolution for winding up the company voluntarily. The labours of the board and of himself as chairman were rapidly approaching completion. They had succeeded in transferring the concern, but it had been necessary for them to distribute £15,000 of their profits in order to enable them to secure £6,000, a sum they were compelled to obtain, as without it the transfer could not have been carried through. The new company, the Typewriting Telegraph Corporation (Ltd.) had been successfully launched, and he believed had a great future before it. The first meeting of that company would be held this week, when the chairman, Sir James Fergusson, M.P., would have an interesting statement to make respecting the invention forming the company's patent. The motion for winding-up was agreed to. (On Oct. 24 a motion is to be heard in the High Court for winding-up Recording Telegraphs (Ltd.) under the supervision of the Court. Messrs. Maddisons, 6, Old Jewry, London, are solicitors for the plaintiffs.)

ST. HELENS AND DISTRICT TRAMWAYS CO. (LTD.)—The directors' report for the 19 months ended June 30, just issued, states that the Corporation of St. Helens have made great efforts to lay down and equip the tramways within the district, but the work has not been completed as expeditiously as the directors desired. For seven months no part of the electrical system was available for use, and up to June 30 only one-half of the projected lines had been handed over to the company. The service of cars has given general satisfaction, and the traffic receipts have been larger and progressive. In consequence of the delay the net revenue has not been sufficient to provide for the whole of the rental charged by the Corporation and the premiums upon the redemption policies, and it has therefore been decided to carry forward £1,500 of the rentals to be extinguished out of future profits, and to treat the premiums already paid as an asset.

NEW COMPANIES, STATUTORY RETURNS, &c.

GENERAL ELECTRIC CO. (1900) (LTD.)—This company was registered on Sept. 27, with a capital of £800,000 in £10 shares, to acquire the business of the company of the same name (registered in 1889), to manufacture and deal in electrical appliances, machinery and apparatus, and to carry on the business of electricians, electrical and general engineers, ironmongers, makers of electric tramcars, motor cars and carriages, dynamo and motor manufacturers, and makers of telephones, bells, electroliers, arc and other lamps, electric light fittings, indiarubber, asbestos and other insulating materials, &c. The subscribers (with one share each) are Gustave Byng (manufacturer), Max Byng (electrical engineer), H. Hirst (electrical engineer), A. Eckstein (electrical engineer), W. White (electrical engineer), E. Wilson, and T. J. K. Alwood. The first four subscribers are the first directors. Qualification, 1,000 shares. (See also notice under "CITY NOTES."

SUSSMANN ELECTRIC MINERS' LAMP CO. (LTD.)—This company was registered on Sept. 26, with a capital of £30,000 in £1 shares, to acquire the business of the Sussmann Electric Miners' Lamp Co. (Ltd.), and to carry on the business of manufacturers of miners' and other lamps, galvanic battery manufacturers, manufacturers of and dealers in electrical, chemical, and other apparatus, appliances and materials, &c.

WALKER AND HODGETTS (LTD.)—This company was registered on Sept. 27, with a capital of £5,000 in £1 shares to acquire the business carried on by Messrs. E. O. Walker and W. H. Hodgetts, and to carry on the business of electricians, electrical and mechanical engineers, electrical and other engine, motor, and machine makers, &c. The first directors are F. A. Moershell, A. Tongue (chairman), E. O. Walker, and W. B. Hodgetts.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since July 19, 1900). Price of silver 28 15/16d. per oz. (Oct. 4). Consols (2¾ per cent.) 98 1/16—98 3/8 for money, 98 3/8—98 7/16 for account; 2½ per cent. 96 7/8—97 1/8 (Oct. 4). Stocks and Shares Continuation Days, Oct. 10 and 24; Ticket Days, Oct. 11 and 25; Pay Days, Oct. 12 and 26; Mining Share Carry-over Days, Oct. 9 and 23.

ANGLO-AMERICAN TELEGRAPH CO. (LTD.)—After placing £6,000 to renewal fund the directors have declared an interim dividend for the quarter ended Sept. 30 of 15s. per cent. on the ordinary and and £1. 10s. per cent. on the preferred stock (less tax), payable Nov. 1.

GENERAL ELECTRIC CO. (LTD.)—In reference to an announcement which appears in another column under "New Companies," the prospectus of the General Electric Co., inviting applications to a capital of £800,000 will, we are informed, be issued early next week.

MUNICIPAL LOANS.—During the week the Huddersfield Corporation invited applications for £750,000 3 per cent. redeemable stock at £96. 10s. for tramway, electricity supply, and other purposes.

Croydon Corporation have also this week made an issue of £500,000 3 per cent. stock at £96 to provide money for the construction and completion of electric lighting and electric tramway works, &c.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee has appointed 11th inst. a special settling day in the further issue of 50,000 £10 shares (issued at £3 premium), £6 paid (£3 capital and £3 premium), and numbered 250,001 to 300,000, of the *Eastern Extension Telegraph Co. (Ltd.)*, and has ordered the securities, as well as the further issue of 1,600 5 per cent. non-cumulative £10 fully-paid preference shares (Nos. 37,001 to 38,600) of the *British Columbia Electric Railway Co. (Ltd.)* to be quoted in the official list. Application has been made to the committee to appoint a settling day in and to grant a quotation to the further issue of 23,361 £5 5 per cent. cumulative preference shares of the *United River Plate Telephone Co. (Ltd.)*. The committee has also been asked to allow £500,000 4 per cent. debenture stock of the *National Telephone Co. (Ltd.)* to be quoted in the official list.

SUBMARINE CABLES TRUST.—The coupon due Oct. 15 will be paid by Messrs. Glyn, Mills, Currie & Co., 67, Lombard-street, E.C., on that date, as announced in an advertisement on another page.

NOTES.

In another column will be found a translation of an important Paper by M. LEBLANC, read before the International Congress of Electricians, held recently in Paris. The Paper describes M. LEBLANC's method of compounding for both continuous and alternating-current machines, the chief advantage in the case of the former being that a machine with a very small air-gap, somewhat after the fashion of the carcass of an induction motor, can be employed; while in the case of the alternator the excellence of the compounding is the more noticeable feature. The method can be applied to alternators of the polar as well as what may be called the "induction" type (though the regulation with the latter type is the better of the two), and in outline it may be said to consist in the excitation of the alternator field by means of a special form of exciter which in turn is excited partly by a circuit in series with the alternator armature, and partly by a second circuit in shunt with that armature, the proportions being so arranged that the alternator gives a constant voltage with varying load and power factor. Machines constructed in accordance with this principle are now at work at the Paris Exhibition with more or less satisfactory results, though it can scarcely yet be said that sufficient experience has been gained to admit of prophecy as to the ultimate value of the method in practice. Descriptions of two of these machines have already appeared in our columns. The idea of compounding alternating-current machines is of course not a new one, and the author makes reference to the work of MM. BLONDEL and BOUCHEROT in this connection. We might further add that the General Electric Co., of America have manufactured similar machines, in which the compounding is effected by means of an exciter on the main shaft, through the armature of which currents from the alternator pass, and by their reaction upon the exciter fields vary the exciting voltage proportionately to the requirements of the alternator field. These machines are said to give excellent results. The success of M. LEBLANC's proposed continuous-current machines will depend chiefly upon whether or not they can be more economically built than machines of the ordinary bipolar or multipolar type, and here also we must wait for further experience to be gained.

A bold attempt towards an extension of facilities for municipal trading is about to be made by the Bradford Corporation. By a large majority, the Corporation has decided to apply next session for parliamentary powers to acquire a coal mine for the purpose of coal supply to their various undertakings. We shall be curious to see whether the new Conservative Parliament will offer any encouragement to novel proposals of this kind.

SHEFFIELD has had full opportunity to discover the disadvantages of a single-phase alternating current system for general supply purposes. A year ago, Mr. ROBERT HAMMOND, being consulted as to what had best be done, advised a change-over to continuous current in the central supply area, but the late Mr. JOHNSON, the resident engineer, thought that the expense of Mr. HAMMOND's scheme was too great, and recommended that in view of local conditions, of which Mr. HAMMOND could not have such an intimate knowledge as himself, it was preferable to forego all idea of a continuous-current system for the present. Mr. HAMMOND being asked to report on Mr. JOHNSON's report, explained at length that he was not convinced by Mr. JOHNSON's reasoning. Nothing definite in the way of modifying the present system was decided upon, however, and Mr. FEDDEN, who was appointed to succeed Mr. JOHNSON, in turn presented his report—the fourth of the series. We published an abstract of this

Digitized by Google

document in our issue of September 7th, and commented on it. Its main recommendation is to retain the single-phase system and reduce the frequency from 100 ∿ per second to 50. This week we give in another column an epitome of the fifth report, in which Mr. HAMMOND announces himself to be in "entire accord" and "complete agreement" with Mr. FEDDEN, having on this occasion had "fuller data laid before him." It is encouraging to find a consulting engineer with such an open mind, but notwithstanding this the play is hardly concluded yet. Mr. FEDDEN is visiting Paris, Frankfort, and Nuremberg with a view to gaining still further knowledge for the benefit of his Corporation, and, when he returns, no doubt the sixth report on the question will be presented. But what if in a seventh report Mr. HAMMOND is no longer in entire accord and complete agreement with Mr. FEDDEN? With its great caution and anxiety to do exactly the most correct thing with regard to electric lighting, it is surprising that the Sheffield Corporation ever made up its mind to buy out the old company.

A YEAR of unexampled prosperity in New Zealand has operated beneficially upon the finances of the Telegraph Department of that colony. According to the annual report of the Telegraph Commissioner for the year ended March 31st last, the increase of revenue from the combined telegraph and telephone services amounted to no less than 13·13 per cent. over the previous year, which itself exceeded the year 1897 by 4·73 per cent. Like the same services in the mother country, and in some other of the colonies, the telegraph and telephone of New Zealand are still worked at a loss—but a loss which shows signs of gradual conversion into a profit. On the telegraphs the balance of expenditure over revenue is about £17,000; on the telephone service a little over £8,000. Considering the comparative newness of both services, and the adverse tariff with which the telegraph was handicapped prior to 1896, their present position and prospects may be regarded as fairly satisfactory. We should be glad to see its differential element removed out of the tariff altogether—the so-called "urgent" telegrams bearing no sort of proportion to the "ordinary" either in number or in their tendency to grow. The department, we are sorry to notice, has suffered severely during the past year from mortality among its principal officers, foremost of these being Mr. E. H. BOLD, Inspector of Telegraphs, and Mr. W. C. SMYTHE, electrician.

Appointment.—It is announced that the First Commissioner of Works has appointed Mr. W. H. Massey to be consulting electrical engineer to Her Majesty's office of works for the Royal Palaces and public buildings in charge of that department.

The Galveston Disaster.—The damage caused to the shore ends of the cables and to the land telegraph lines by the terrible hurricane which visited Galveston, U.S.A., on the 10th ult., has now been repaired, and we are able to announce the complete restoration of telegraphic communication via Galveston with Mexico and Central and South America.

Institution of Electrical Engineers.—The first meeting of the new session of the Institution of Electrical Engineers will be held in the rooms of the Institution of Civil Engineers at 8 p.m. on Thursday, November 8th, when the premiums for the session 1899-1900 will be presented, and the president, Prof. John Perry, F.R.S., will deliver his inaugural address.

The Chifu-Tsin-tau Cable.—Reuter states that the cable between Chifu and Tsin-tau, laid for account of the German Government, was opened for the transmission of messages on the 5th inst. The territory of Kiao-Chau is thus joined to the international cable system of the Eastern Extension and Great Northern Companies. No change is made in the tariff.

Cable Interruptions:—	Date of Interruption.
Latakia—Cyprus	June 21, 1899
Tangier—Tarifa	Jan. 3, 1900
Ceara—Maranham	Feb. 20, 1900
Pará—Maranham	Mar. 2, 1900
Môle-St. Nicolas—Cap Haitien	Mar. 7, 1900
Zanzibar—Mombasa	Sept. 20, 1900
Paramaribo—Cayenne	Oct. 6, 1900

The "Twopenny Tube."—In our last issue we referred to the failures predicted for the Central London Railway. The following amusing explanation of its success appears in an American contemporary:—

> The great success of the Central London is just waking things up. The line has an advertising agent that is a corker. He succeeds in getting an article into each of the daily papers every day, and besides this he has an editorial about once a week; then he has a topical song in each music hall every night. The consequence is that the "Twopenny Tube" is the talk of the town and its receipts are beyond expectation.

Electrical Progress in Corea.—*Engineering* states that an electric railway, under the management of an American company, is now open at Söel, and is doing fairly well, although some of the natives view the "spirit" which works it with apprehension, and sometimes make attempts to destroy the plant. Various other developments in the applications of electricity are taking place, and now Söel has the largest electric plant in the Far East, with the exception of that of Tokio. On June 4 it was officially announced that a telegraphic service between the Fusan and Chemulpo post offices on the one side and various places in China, via Söel and Wijn on the other, had been opened. The fee for the service within the limits of Corea is fixed at 20 sen (about 10d.) per word, while that between Corea and China is 62 sen per word.

University of London.—A general meeting of Convocation was held on Tuesday, at South Kensington, to appoint members of the Senate of the reconstituted University of London. Before proceeding to the election a resolution of condolence with Her Majesty the Queen on the occasion of the death of the Duke of Saxe-Cobourg and Gotha was passed. Among the persons nominated for election by the registered graduates in art are Mr J. Fletcher Moulton, M.A., and Sir Albert K. Rollit, LL.D., B.A.; and the following is the result of the election by the registered graduates in science. The figures following the names indicate the number of votes in each case:—

Elected.—Sir Philip Magnus, B.A., B.Sc. (432); Sophia Bryant, D.Sc. (429); Charles William Kimmins, D.Sc. (364); Frank Clowes, D.Sc. (333); Silvanus Phillips Thompson, D.Sc., B.A. (239); Francis Sowerby Macaulay, D.Sc. (226). *Not elected.*—Sydney Russell Wells, M.D., B.Sc. (223); Sydney Howard Vines, D.Sc. (219); George Carey Foster, B.A. (213); Robert Davies Roberts, D.Sc. (147); Charles Henry Draper, D.Sc., B.A. (142).

Central Technical College Old Students' Association.—The Old Students' Association of the Central Technical College held its third annual dinner on Tuesday, October 2nd, in London, Prof. O. Henrici, President of the College and Dean of the Association, being in the chair. The speakers were the Chairman, Prof. W. E. Ayrton, Prof. W. C. Unwin, Messrs. O'Gorman, Armstrong and Ackermann, and Sir A. R. Binnie, who was the guest of the evening. This Association is not the first Old Students' Association that has been formed in connection with the Central Technical College. An Old Students' Association of students of both the Finsbury Technical College and the Central Technical College (then the Central Institution), flourished for several years, and in addition to purely social functions some excellent Papers were read and discussed at its meetings. Unfortunately the Association died a natural death several years ago. The present Old Students' Association of the Central Technical College has now been in existence for three or four years, and it is to be hoped that it will be a permanent one. It is to be regretted, however, that its membership should be chiefly confined to men who were students at the

Digitized by Google

college only a few years ago. There are many old students from the earlier days of the Central Institution who hardly know of the existence of the new Association, but who, we are convinced, would gladly join it with a view to renewing acquaintance with some of their former comrades. The name and address of the hon. secretary of the Association is Mr. Maurice Solomon, 12, Edith-road, West Kensington, London, W.

Trials of Electric Motor Cars.—The Automobile Club announces a series of trials of electric vehicles to be held from Monday, November 5th to Friday, November 9th. The following are the preliminary programme and conditions:—

1. Vehicles must be entered on or before Friday, November 2nd. The entry fee is two guineas per vehicle per trial. Forms of entry may be obtained after Friday next, October 12th, on application to the Secretary, Automobile Club, 4, Whitehall-court, London, S.W.

2. Vehicles entered may be subjected to the following trials:—

Monday, November 5th.—A run over a given course for an unlimited distance on one charge, the driver to declare to the observer when the run is to be considered as finished.

Tuesday, November 6th.—A course of 30 miles, to include considerable gradients.

Wednesday, November 7th.—A course of 30 miles of average road.

Thursday, November 8th.—A course of 30 miles of flat or nearly flat road.

3. Vehicles may be entered on or before Friday, November 2nd, for an additional optional trial, viz., on Friday, November 9th, as follows: A run over a given course for an unlimited distance on one charge, the driver to declare to the observer when the run is to be considered as finished.

4. The same batteries will be used throughout, and during the course of the trials will be under the supervision of the Club. Competitors are responsible for the supervision of the charging of their batteries.

5. The energy consumed, number of passengers carried and average speed attained, will be recorded on certificates which will be granted by the Club to competitors, but no speed in excess of the legal limit of 12 miles per hour will be recorded or recognised. Competitors must supply drivers for their vehicles, and must provide on each vehicle a seat for an official observer. The routes on which the trials will take place will be within 50 miles of London, but will not be made known to competitors until immediately before the trials. Competitors are required to fit to their vehicles reliable and accurate voltmeters and ammeters which can be read during the trials by the observers, and these meters must be fitted with terminals by means of which they may be tested by the judges. In entering vehicles, competitors are requested to kindly supply, for the information of the judges only, a diagram of the electrical connections of each vehicle. A competitor, by entering a vehicle, thereby agrees to be bound by the rules and decisions of the Judges' Committee in all matters, and the Judges' Committee reserves to itself the right to amend the rules affecting the trials.

Electric Lighting Provisional Orders.—In the Board of Trade return respecting the applications for provisional orders under the Electric Lighting Acts, 1882-1890, it is stated that during last Session 108 applications were made (59 by local authorities and 49 by companies). A full list appeared in our issue of January 5th last. Only nine of these applications were refused, but some of the orders were only granted with modifications. Thus the Liverpool District Lighting Co. were successful in regard to Allerton, Much Woolton, Little Woolton and Childwall, Garston being excluded. The application of the Urban Electric Supply Co. for Bridge of Allan and Dumblane was only granted for the latter district, as the Board refused to include two non-contiguous areas in one order. The Cheltenham Town Council obtained an order for Charlton Kings, but failed to obtain the consent of the Cheltenham and Winchcombe rural districts. The County of Durham Electrical Power Distribution Co. having failed to produce the sanction of the Chester-le-Street (Seaham Harbour) District Council, their application was refused. This company was successful in regard to Jarrow, but the Hebburn and Felling districts were excluded, the local authority of the latter district having withheld its consent, and the Hebburn Council having itself made application for an order. On the other hand, the Freshwater and Totland (I.W.) Electricity Supply Co. had obtained conditional consent to their application, and after inquiry the Board of Trade decided to dispense with the sanction of the local authority, and granted the order. The County of London Company obtained their order for Battersea, the consent of the Vestry having been dispensed with. The Lambeth application failed, as the promoters were unable to obtain the sanction of the Vestry. An inquiry was held into the application of the Marylebone Electric Supply Co. for an order for Marylebone (London), and the Board of Trade decided in favour of the application, but our readers will remember that the confirmatory bill was rejected on the second reading in the House of Commons. There were two applications for Ramsgate, but preference was given to that of the Corporation, the Isle of Thanet Electric Tramways and Lighting Co.'s application being refused. The Midland Electric Corporation for Power Distribution obtained powers for Upper Penn (Seisdon) and Bushbury (Cannock). The application of the Midland Electric Light and Power Co. for Leamington was opposed by the Town Council, but the Board of Trade decided to dispense with the consent of the Council, and granted the order, subject to its not coming into force until the local authority had made default in putting into operation the order obtained by them in 1899. This has, we understand, taken place, and the company's order has come into force. The Southwold Corporation also failed in their application for a provisional order because "they failed to satisfy the Board of Trade that they were in a position financially to give effect to the order if granted." The Electrical Power Distribution Co. were opposed by the Councils of Neath, Briton Ferry and Aberavon, and consequently the application for these districts was rejected. The same company at Staines, Chertsey, and Egham had won over the local authorities of the two former districts, and the Board of Trade decided to dispense with the consent of the Egham Council and granted the order. The Richmond (Surrey) Electric Light and Power Co. did not proceed with their application for Twickenham and Teddington, and the Twickenham and Teddington Electric Supply Co. succeeded in their application for Twickenham, the Teddington local authority dissenting from the application. The Uxbridge and District Development Syndicate obtained an order for Uxbridge, Hillingdon East, Ickenham, Cowley, Hayes, and Denham. There were no applications for licences during the past year, but the following transfers of orders were effected:—

Audenshaw (1899), Droylsden (1897) and Heaton Norris (1899) to Manchester Corporation; Barnet (1893) and Hertford (1891) to North Metropolitan Electrical Power Distribution Co; Carshalton (1898) and Sutton (1892) to County of Surrey Electrical Power Distribution Co.; Gateshead (1899) to County of Durham Electrical Power Distribution Co.; Godalming (1896) to Urban Electric Supply Co.; Lewes (1898) to County of Sussex Electrical Power Distribution Co.; Margate (1896) to Isle of Thanet Electric Tramways and Lighting Co.; Weston-super-Mare (1891) to Weston-super-Mare District Electric Supply Co.; and Whiston (1898) to British Insulated Wire Co.

From 1883 to date the Board of Trade have dealt with 758 applications for orders, and of these 547 were granted and 541 were confirmed by Parliament. Of the 32 licences granted since 1883 only one, that of the Ingleton Electric Lighting and Power Co. (granted in 1899), is now in force. 111 provisional orders have also been revoked or repealed, but we would like to direct attention to a few of the instances in which local authorities have been in possession of orders for years, but have done nothing to put their provisions into force. Newbury Town Council obtained an order so far back as 1892, Clonmel (Ireland) Town Council and Yeadon District Council in 1894, Swindon New Town District Council in 1895, Kettering District Council in 1896, and Wells Corporation in 1896. It would be interesting to know how these orders have so long escaped revocation by the Board of Trade. Another glaring case is that of Dorking, where the Urban District Council obtained a provisional order in 1897, and actually decided to shelve it for five years, refusing subsequently (in June, 1899) an offer of the Electrical Power Distribution Co. to purchase the order.

MEETINGS OF SCIENTIFIC AND ENGINEERING SOCIETIES, &c.

FRIDAY, October 12th.

ELECTRO-HARMONIC SOCIETY.

8 p.m. First Smoking Concert, at St. James's Hall Restaurant.

WEDNESDAY, October 17th.

ROYAL MICROSCOPICAL SOCIETY.

7:30 p.m. Meeting at 20, Hanover-square, W.

FRIDAY, October 19th.

INSTITUTION OF MECHANICAL ENGINEERS.

8 p.m. First General Meeting of the Session. Paper to be read and discussed: "Observations on an Improved Glass Revealer for Studying Condensation in Steam Engine Cylinders, and Rendering the Effects Visible," by Bryan Donkin.

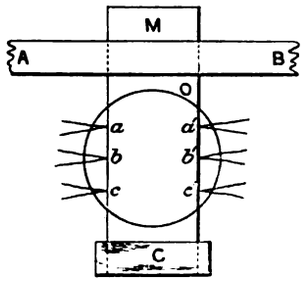
CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Thermo-magnetic Phenomena.—When a thin metallic plate is placed in a strong magnetic field perpendicular to the lines of force, there are four electro-thermal phenomena which have been successively discovered by Hall, von Ettinghausen, Nernst, and Leduc. An electric current traversing the plate from one edge to the other produces a difference of potential and a difference of temperature at the other two edges. A current of heat produces the same two effects. All these phenomena are well developed in bismuth, while in the other metals only the Hall effect and the Nernst effect are evident. G. Moreau now shows that these two effects are in reality identical, by proving that the one follows from the other, and that their coefficients are of the same order and sign. The theoretical conection between the two phenomena is traced by means of Kelvin's specific heat of electricity σ, and the relation between the coefficient K of the Nernst effect and the coefficient c of the Hall effect is given by the formula $K=\frac{\sigma c}{\rho}$, where ρ is the resistivity of the metal. The author's experiments were conducted with the device shown in the diagram, where M is the plate under investigation. The current—electric or thermal—is conveyed through the copper bar AB into M, and out by the mercury bath C. A, B and C act either as electric terminals or as heat channels. The temperature gradient is determined by the thermo-couples *abc*, *a'b'c'*, situated within the circle O of uniform magnetic field intensity, and the distribution of potential is found by using one wire out of every thermo-couple. Thus the thermal and electric conditions are completely known. The author shows that in steel, iron, cobalt and nickel, the Hall and Nernst effects are both proportional to



the magnetisation of the plate, and their reversal occurs at about the same temperature. The above formula is verified to within 8 per cent., but certain irregularities observed in the case of nickel lead to its amplification in the sense that the Nernst effect is a Hall effect with respect to Thomson's "true contact E.M.F."

[G. Moreau, *Journ. de Physique*, Sept., 1900.]

Platinum Resistance Thermometer.—H. M. Tory has carried out an investigation, suggested by Callendar, with a view to determining the probable order of accuracy in the determination of high temperatures attainable by the use of ordinary commercial specimens of platinum wire. Five wires in all were compared over the range of 400°C. to 1,000°C. The fundamental temperature coefficients of the resistances varied from 0·003892 to 0·002340, *i.e.*, by 40 per cent. of the maximum value. It was found, however, that the extreme variations of the temperatures observed, when calculated on the platinum scale by the formula $pt=100\,(R-R_0)/(R_1-R_0)$, in which R, R_1, and R_0 stand for the observed resistance at the temperatures *pt*, 100deg. and 0deg. respectively, did not in any case exceed 9deg. at 1,000°C., or were less than 1 per cent. on the interval at any point of the rate of observation, in spite of the larger differences in the samples. It is probable that the platinum wires used were free from contamination with baser metals outside the platinum group. Wire-drawing produced no effect if the annealing was carefully carried out subsequently. In all cases, the wires with the smallest temperature coefficients had the largest specific resistance, and usually gave the lowest platinum temperatures.

[H. M. Tory, *Phil. Mag.*, October, 1900.]

THE ACTION OF WATER UPON INDIA-RUBBER.

BY HUBERT L. TERRY, F.I.C.

Water does not percolate through rubber with any great rapidity, but that it does pass through it to an appreciable extent, and at ordinary atmospheric pressure, was demonstrated a great many years ago by Thomas Hancock, quite the most astute and laborious worker the field of india-rubber has known. To quote Hancock's own words, "I suspected rubber was not entirely impervious to water, and I had the curiosity to make a bag of canvas lined with sheet rubber, which I filled with water and sealed hermetically." The result of this test is shown in the following series of figures:

		lb.	oz.	dr.
The weight on Oct. 21, 1826 was	.....	1	1	4
Ditto Oct. 25, 1827	.....	1	1	2
Ditto Oct. 2, 1835	.....	1	0	0
Ditto Nov. 1844	.....		14	12
Ditto Oct. 1849	....		13	4
Ditto Feb. 1851	.....		7	8
Ditto May 1854	....		3	14

Two years later the bag, when cut open, was found to be quite dry, showing that the whole of the water, rather more than 12oz., had escaped in the 30 years which had elapsed since the bag was filled. It is not every experimenter of the present day who has the patience to wait 30 years for his results, and although many experiments dealing with the absorption of water by rubber have been conducted at various times I do not know of any published results which cover so much time and which are so conclusive as those published by Hancock. A point, however, which must not be overlooked is the fact that the above figures relate to pure or unvulcanised rubber, a body which can be shown by means of the microscope to contain innumerable minute pores. With vulcanised rubber the case is quite different, and this product at ordinary pressures may be considered as almost impervious to water unless it is extremely attenuated, although I am unable, in support of this statement, to give any figures corresponding in value to those of Hancock as far as extended observation is concerned.

Reference has been made to the facts that Hancock's experiment with pure rubber was conducted at the ordinary pressure of the air, and that the impermeability of vulcanised rubber relates also to ordinary pressures. That increased pressures tend to increase the amount of water which rubber will absorb may be considered as proved. With regard to the action of water upon pure rubber under pressure, it may be mentioned that quite recently experiments in relation to this subject have been carried out at the Charlottenburg testing laboratory at Berlin, and as one result it was shown that the same amount of water absorbed in two hours at ordinary pressures was taken up in 5min. when the pressure was raised to 8 atmospheres. With regard to the exact amount of water taken up by rubber at ordinary pressures the figures given by different observers show considerable variation, but this may probably be accounted for by the fact of the thickness of the rubber sheet not being identical in each case. The Charlottenburg authorities give 8 per cent. to 35 per cent., though why the range should be so extensive is not easily apparent. Dr. Obach has given 24 per cent. as the absorption of water in four months, and although I can endorse this figure I have obtained such varying results with rubber of different composition, and have found that so much depends upon the details of the experiments, that I am disinclined to give any definite figure myself until I am in a position to treat of the matter in detail. An important point in connection with such tests is to see that the surface of the rubber is clean, that is, that it is free from the various chemicals which the manufacturers apply to the surface to destroy the tendency of the rubber to adhere when it is rolled up. The exact nature of the treatment to which the rubber is subjected by the different manufacturers to effect this end comes under the category of trade secrets, and need not be entered into here, but it is right that the fact should be mentioned, and it is also advisable to say that the processes adopted by the different manufacturers are not identical. From what has been said it will be seen that the sheet rubber employed in

Digitized by Google

one case may have had its tendency to absorb water affected to a greater degree than in other cases, and this I venture to suggest may account to some extent for the discrepancies noticeable in the figures given by various observers in regard to the exact amount of water which such rubber is capable of absorbing at ordinary pressures.

If any further proof is wanted about this absorption we have the evidence which is derived from the washing and drying of the crude rubber in the works. The rubber, which is washed on fluted rollers, is hung up in the form of sheets in stoves maintained at a temperature of about 100°F. The drying process may take four or five days for completion, though over 90 per cent. of the water which is present is removed in a few hours, especially if a current of air circulates in the stove. It is the last few per cent. of water which is so difficult of removal, and it is not at all improbable that this is fixed in some sort of way, chemical or physical, in the pores of the rubber. The thinner the sheet of rubber is, the quicker does the removal of this last few per cent. of water take place, though where the amount of material to be dried is large, the cubic drying space available in a works is not always sufficient to allow of the production of very thin sheets.

To turn now more particularly to the action of water upon rubber it may be asked whether this is entirely physical or if it induces any chemical change in the material. As far as we know with any certainty the change can only be described as a physical one, the effects being increase of bulk and diminution of adhesiveness and tenacity. In driving off the water by heat the rubber apparently suffers some injury, rendering it more prone to decay, but this, it is at once seen, cannot fairly be described as the effect of the water alone. When pure rubber is allowed to stand in water for any length of time it certainly undergoes some kind of decomposition, though I am not aware that the precise nature of the change has been shown. Of course the uses of pure rubber are very limited compared with those to which the vulcanised product is put, and in the case of its principal application for cable purposes—I refer to the layer of sheet usually lapped as a first coating round the wire—it cannot be said that the question of the absorption of water is likely to come into prominence. There may be cases, however, where unvulcanised rubber forms the bulk of the insulation, and I am reminded of some cables for mining explosion purposes which I saw at the exhibit of MM. Geoffry and Delore at the Paris Exhibition, and which were described as being insulated with "natural rubber." This term is usually taken to mean raw rubber which has not undergone any of the processes of mastication, solution or vulcanisation, but in this case presumably means the masticated product referred to in this country as "pure indiarubber."

Although, as has already been stated, the absorption of water by vulcanised rubber is infinitesimal compared with pure rubber, yet figures given by Payen many years ago show that this absorption does take place to some extent, and the fact cannot be ignored by those who propose to put vulcanised rubber cables in water. In this connection it may be said that Mr. Kilgour, in his book on "Electrical Distribution," states that Messrs. Johnson and Phillips believe that the only other system of cable which could compare on the score of efficiency and permanency with the Brooks' oil system is that in which the cables highly insulated with vulcanised rubber or gutta-percha are drawn into iron pipes kept full of water. This no doubt is all right as regards gutta-percha, which remains unaltered under water, but there seems to me to be room for doubt as to the permanency of the rubber cable when laid in this way; at any rate, it seems quite legitimate to prophesy trouble within the limits of infinity, which the term "permanent" rather suggests.

With regard to the important issue of the action of water on deep-sea vulcanised-rubber cables, there seems to be a considerable difference of opinion, and it may be that the idea that rubber is quite unsuitable for this purpose originated in the fact that some of the earlier rubber cables proved unsatisfactory. Perhaps opponents of rubber for this purpose have not paid sufficient attention to the results which have been obtained by improvements in the rubber insulation. Messrs. Hooper recently wrote to the *Indiarubber Journal*, in reply to an article reflecting on the use of rubber for deep-sea work, stating that a vulcanised-rubber cable laid by them 25 years ago in 2,000 fathoms of water is now in perfect condition. The passage of arms which has taken place between Mr. Oscar Schafer in *The Electrician* and Mr. Ira Henry in the *Indiarubber World* has relation more to the probable longevity of the seamless insulation than to any defect which is likely to arise from porosity. But from the fact that the United States Government has recently given an order to the Safety Insulated Wire and Cable Co. of New York, to which firm I understand Mr. Henry belongs, for 400 miles of rubber insulated cable for deep sea purposes, it would seem that the question of porosity is not one that need be seriously considered. In face, then, of what has just been said it would seem that the opponents of rubber insulation from the porosity point of view had perhaps better reconsider their position, which recent experience goes a long way to prove is somewhat untenable. Of course, in referring to the action of water upon rubber it is always necessary to be explicit as to the nature of the rubber, whether highly compounded or not, because the composition of the rubber may have a profound influence in determining its capacity for absorption.

THE PARIS EXHIBITION.—IX.*

(BY OUR SPECIAL CORRESPONDENT.)

Several other countries besides Great Britain, France, and Germany exhibit generating machinery, and, as will have been noticed in the table given in my second article, furnish electrical energy for the light and power supply of the exhibition. The Swiss firms in particular have some fine sets, and the eminent firm of engine makers, Messrs. Sulzer & Co., have been to them somewhat the same as the Augsburg-Nuremberg Co. to the German dynamo firms. Fig. 53 is a general view of the Sulzer exhibit. To the right-hand side is a 1,700 H.P. four-cylinder triple expansion engine, driving a Brown-Boveri alternator, and to the left a 750 H.P. tandem engine coupled to a Rieter flywheel dynamo. The four-cylinder engine is shown in greater detail in Fig. 54, and has the following main dimensions:—

Diameter of H P. cylinder	600mm.
Ditto I.P. ,,	850mm.
Ditto each L.P. cylinder	1,025mm.
Stroke	1,500mm.
Speed	85 revs. per min.
Steam pressure	11 atmos.
Normal output at 30 per cent. cut-off on H.P. cylinder	1,700 I.H.P. = 1,500 E.H.P.
Maximum output at 40 per cent. cut-off on H.P. cylinder	1,950 I.H.P. = 1,750 E.H.P.

The illustration gives a good view of the valve gear, which is of Messrs. Sulzer's usual design, with four-seated valves, the regulator acting on the cut-off of the H.P. cylinder, and the cut-offs of the other cylinder being adjustable by hand. The Brown-Boveri alternator likewise follows the usual lines adopted by its makers. It is designed for 1,000 volts, three-phase current at 42·6 ∽ per second.

Fig. 56 shows a vertical twin tandem engine, driving an Oerlikon 2,200 volts inductor alternator. This develops 350 E.H.P. at 250 revs. per min. Its cylinder diameters are 280mm. and 450mm. with a 400mm. stroke. With 11 atmospheres pressure and at a cut-off of 25 per cent. its output is 385 I.H.P. or 350 E.H.P., and at 45 per cent. cut-off it can furnish 515 I.H.P. or 475 E.H.P. A feature of the engine is the single valve gear for each pair of cylinders. The Oerlikon single-phase alternator coupled to this machine is, as already mentioned, of the inductor type, the stationary field winding being a flat coil of copper ribbon placed between the two sides of the armature winding. The exciter is placed on an extension of the bedplate and is coupled to the main shaft at the end not seen in the illustration. Another similar machine of the inductor type standing near to this one has an

output of 650kw. at 8,000 volts, with a speed of 250 revs. per min., and a frequency of 50 ∽ per sec.

The large machine in Fig. 55 is a 5,500-volt, 1,800 kilovolt-ampere three-phase Oerlikon dynamo driven by an Escher-Wyss engine at 94 revs. per min. It furnishes only about 1,000 kilovolt-amperes single-phase at 2,200 volts, by swallow-tailed keys held by bolts, so that the bolts need only be loosened to remove a pole-piece and its coil. The exciter is a 12-polar ring-wound machine, mounted on the same shaft as the alternator, as seen in Fig. 55, and on account of the slow speed the commutator is of large diameter and has many sections. An exciting current of 80 amperes

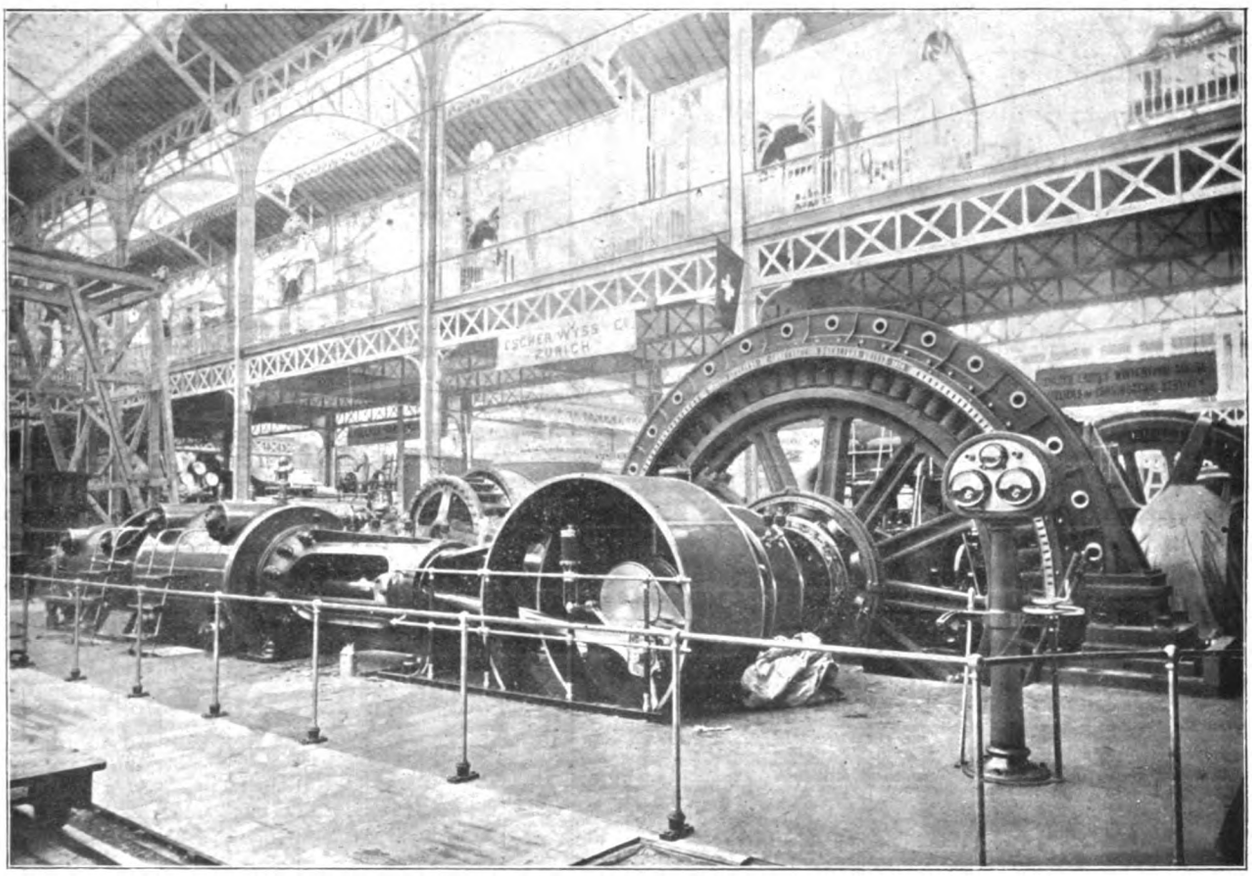

FIG. 55.—ESCHER-WYSS–OERLIKON ALTERNATOR.

however, for the light and power service of the exhibition, the winding of the armature being disposed in parallel to permit of this arrangement. The slots in the armature, which is stationary, are open, and the coils are wound first

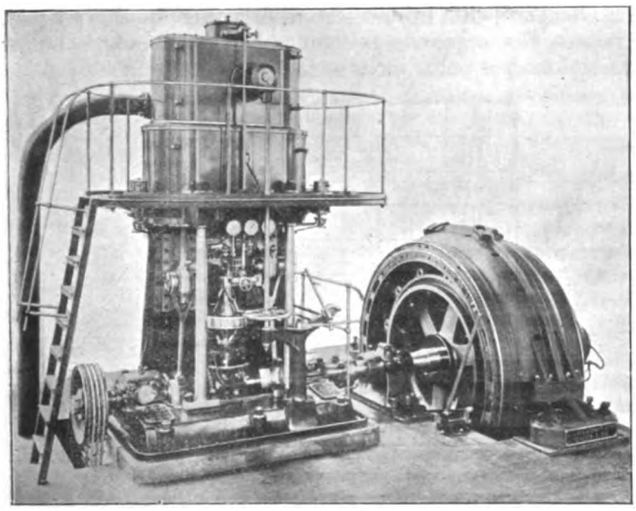

FIG. 56.—SULZER-OERLIKON INDUCTOR ALTERNATOR.

and then slipped in position and held by fibre wedges. As usual, the armature casting is also supported below, as well as on the bed-plate of the dynamo, and on the latter are adjusting screws to permit of exact centreing. The flywheel magnet has 64 poles with laminated cores held in place to 90 amperes at about 100 volts is required. The adjustment of the voltage of the alternator is effected by varying the resistance in the field circuit and in the shunt of the exciter, and following a usual practice on the Continent, the handwheels for making these two adjustments are concentric.

The engine is a tandem Corliss one, with 650mm. and 1,100mm. cylinders and 1,200mm. stroke. The crank-shaft bearings are 400mm. diameter and 750mm. long. A feature is a water cooling arrangement for the crosshead guides. Both cylinders are jacketed, the H.P. cylinder with live steam and the L.P. cylinder with steam from the receiver. Each of the four Corliss valves is driven by an independent eccentric. The ordinary arrangement is adopted of a fixed cut-off, adjustable, however, by hand, on the L.P. cylinder, and a cut-off on the H.P. cylinder regulated by the governor. The latter is of the spring type, and is provided with a speeding gear, by means of which the speed of the engine can be adjusted while the engine is running.

A quaint little barring engine is employed for this engine. It possesses three single-acting cylinders, the cylinders themselves being disposed radially to the crank shaft 120deg. apart. The diameter of each of these cylinders is 110mm., with 100mm. stroke, and the engine runs at 800 revs. per min.

Messrs. Rieter & Co. have a fine exhibit, which includes electrical as well as hydraulic and general engineering apparatus. A three-phase alternator shown by this firm has the stationary armature within instead of external to the field magnets, the latter being a series of poles radiating inwards from the periphery of the rotating wheel. In order to rotate the armature, for inspection and repairs, the latter can be fixed to the field magnet by means of wedges, and rotated with it. An interest-

ing little detail of this machine is the washers employed to keep the field magnet bolts tight. These have a small indentation in them as sketched in Fig. 57, which coincides with a small hole beneath, and after the nut is screwed up one side of the washer is turned up against one face of the nut. This effectually prevents the bolts from working loose. The Alioth Co., and their French house, the Société des Applications Industrielles, also exhibit some

machinery and apparatus, especially in connection with the sub-stations and moving platform, which will be referred to later.

THE SO-CALLED "SKIN EFFECT," OR THE INCREASED RESISTANCE OF IRON WIRES TO ALERNATING CURRENTS.

BY B. HOPPS.

So few data have been published on this subject that the following results and curves may be of some interest. It is a well-known fact* that the resistance offered by an iron rod or strip to alternating currents depends not only on its length, cross-section, and its temperature, but also on the frequency of the current and the magnetic properties of the iron. It is found that the resistance increases the higher the frequency and the greater the permeability of the iron. This increase is more especially marked in the case of wire or rod of circular cross-section.

The following are results of tests made on straight lengths of iron wires and rods of ordinary commercial value, and to ensure a fair average special care was taken to obtain them from various manufacturers. An observed current was passed through the rod, the volts drop due to a known length being measured by means of a low-reading hot-wire voltmeter:—

Dia. of rod in inches.	Length between volt leads in inches.	Amps.	Volts drop.	Cycles per sec.	Apparent resistance in ohms.	True resistance in ohms.	Mic'hms per cubic in.

Figs. 1, 2 and 3 show curves derived from the above tables. From these results it will be seen that the resistance offered to currents of 100 cycles per second by rods of 0·975in. diameter is roughly 16 times that offered to continuous current, this value decreasing with the smaller diameters of rods to only

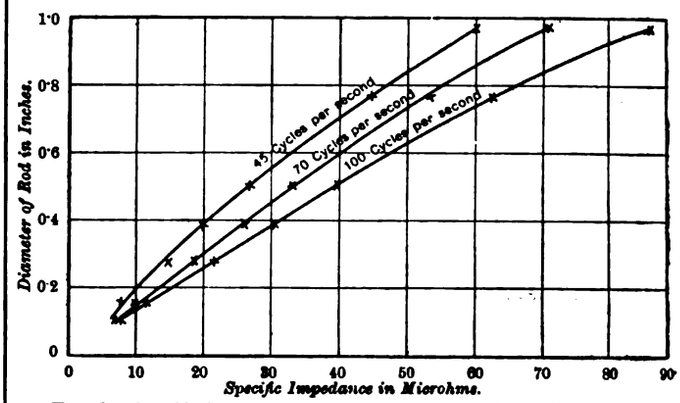

FIG. 1.—Specific Impedance of Iron Rods of varying Diameters at 100, 70 and 45 cycles per second.

1·4 times for a wire 0·105in. diameter. Furthermore, one learns from the results that there is corresponding to each periodicity a certain value for the apparent resistance per unit length below which it cannot be decreased by further increase of

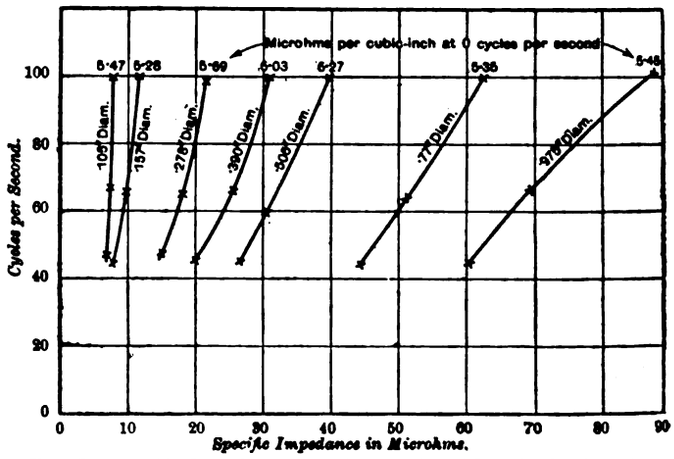

FIG. 2.—Specific Impedance at various Cycles of Iron Rods of varying Diameters.

diameter of the rod. For instance, the curve for 100 cycles, see Fig. 3, shows that no increase of diameter, however great, will reduce the apparent resistance per inch length below 100 microhms per cubic inch.

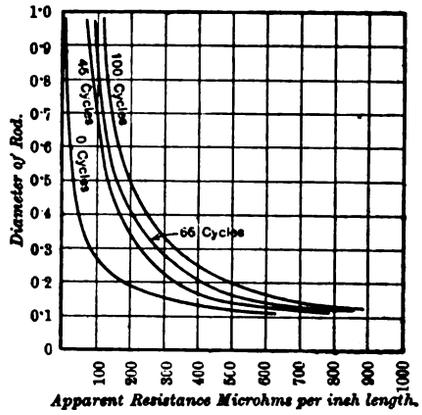

FIG. 3.

It is a matter for further experimenting to determine the nature of this additional resistance, in how far it is of a reactive nature and in how far it is of the nature of ohmic resistance. A delicate wattmeter measurement would enable these resistance components to be separated and would be of still further interest in connection with this subject.

THE LIGHT EMITTED BY THE CONTINUOUS-CURRENT ARC.*

BY MRS. AYRTON.

Among the curves which Prof. Ayrton showed at Chicago in 1893 there were several connecting the mean spherical candle-power of the arc with the current, for given distances between the carbons. The carbons used in these experiments were a 13mm. cored positive and a solid negative of 11mm. From these curves he concluded that, with the same current, the candle-power increased with the distance between the carbons up to a certain point and then diminished, so that with any given carbons there was, for each current, a definite length of arc at which a maximum candle-power was obtained. This new and unexpected result was confirmed by Prof. Carhart, who deduced it from his own experiments independently, and announced it at the same meeting, but from a rather different point of view. He found that, with a constant current, the candle-power reached the maximum with certain difference of potential between the carbons. Now, with given carbons and a given current, the difference of potential between the carbons depends only on the distance between them; so that the two discoveries relate to the same fact—a fact which, until now, has not been explained.

In order to study this phenomenon, I plotted curves connecting the mean spherical candle-power with the *length of the arc* for constant currents, utilising the experiments of Prof. Ayrton. I found that not only did these curves show the maximum point which Prof. Ayrton announced, but that those which related to currents greater than 10 amperes had also minimum points at a distance between the carbons of about 2mm., the curves having the form indicated in Fig. 1. In order to assure myself that for these minimum points with large currents Prof. Ayrton's experiments were confirmed by the researches of other observers, I examined the remarkable series of experiments which M. Blondel published in 1897. M. Blondel did not trace the curves connecting luminous intensity with length of arc at a constant current, but the connection between the luminous intensity with the difference of potential between the carbons. As he did not employ currents greater than 10 amperes, the indications which his curves give of a diminution in the total flux of light with arcs of about 2mm. seemed only to be errors of observation. Nevertheless, they existed, and, on plotting from M. Blondel's admirable tables the curves connecting the total flux of light with the length of the arc, I found quite a number which showed indentations (for 2mm. or 3mm. arcs), and one especially where there was an actual minimum point. M. Blondel's experiments were very complete. They were made with arcs from 0mm. to 11mm., 12mm., and sometimes even 16mm. long, and they therefore give us the entire form of the curves from an arc of 0mm. to that at which the candle-power practically no longer changes when the arc is lengthened. This complete curve for large currents has usually the form shown in the top curve in Fig. 2.

This curve shows that, after separating the carbons, with a sufficiently large constant current, the light first increases to a maximum as the arc is lengthened, then, with a slightly longer arc, it diminishes to a minimum, and, with a still longer arc it increases again to a second maximum.

To verify the first maximum point and the minimum point, Messrs. Newton and Good carried out some experiments for me at the Central Technical College, and these experiments entirely confirm those of Prof. Ayrton and M. Blondel. Messrs. Newton and Good compared the candle-power of two 30-ampere arcs, one with a length of 1mm. and the other of 2mm., using a 13mm. cored carbon and an 11mm. solid carbon identical with those used by Prof. Ayrton. The experiments lasted four days, and minute precautions were taken to ensure that the conditions were absolutely the same in the two arcs, even to the point of interchanging the positions of the two arcs. In 17 of the 18 experiments which they made, the 1mm. arc had a candle-power greater than that of the 2mm. arc—which appears fairly conclusive.

In order to see how far it would be possible to predict this singular fact, we must examine in detail the different sources of light in the arc. There are five, which I arrange in the order of their importance:—

1. The crater.
2. The white spot at the extremity of the negative carbon.
3. The vapour.
4 and 5. The red parts of the carbons.

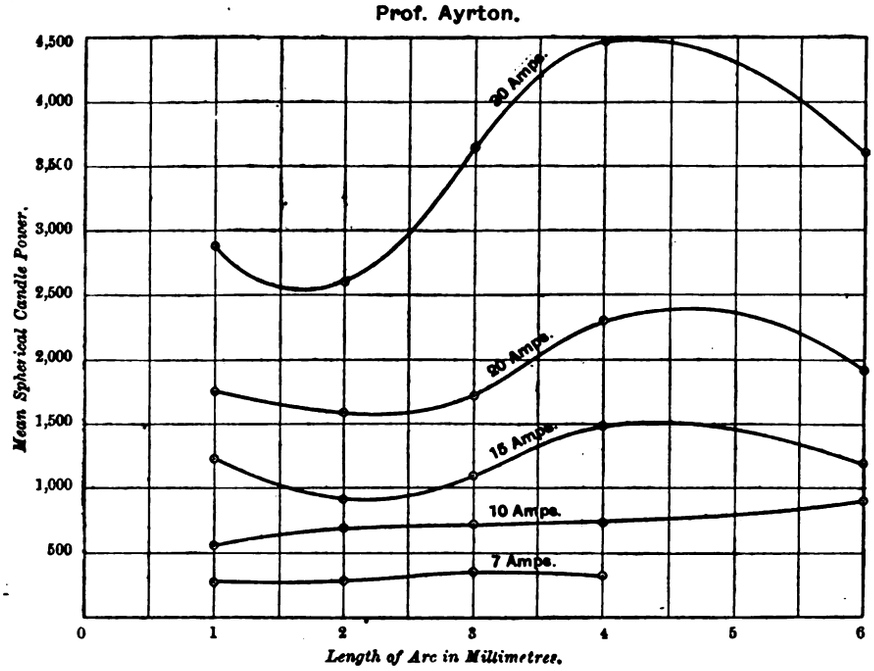

FIG. 1.—Curves connecting Mean Spherical Candle-Power with Length of Arc for Various Constant Currents.
Carbons:—Positive, 13mm. cored; negative, 11mm. solid.

As is well known, it is the crater which gives the greater part of the light, only all that is produced there does not succeed in passing the negative carbon; so that when the carbons are very close together nearly all this light is shut in. The longer the arc the more light can escape from the crater, and the arc does not need to be very long to enable, practically, all the light to pass. Thus, supposing that the intrinsic brilliancy of the crater (the flux of light emitted per square millimetre) does not diminish, and that its area does not diminish either, the quantity of crater light which can pass the negative carbon must increase continuously but at a diminishing rate as the arc is lengthened. Now as long ago as 1881, Capt. Abney (now Sir W. de W. Abney) found that the intrinsic brilliancy of the crater was quite constant for given carbons, depending neither on the current nor on the length of the arc. In 1896 I pointed out, at Toronto, that, far from diminishing, the area of the crater increases a little when the arc is lengthened with a constant current. In consequence, it would seem as if the curve representing the relation between the useful portion of the light of the crater and the length of arc must take the form shown in Fig. 3.

As for the other four sources of light, I have found that the area of the white spot is constant with constant current; consequently, its useful light must increase with the length of the arc, for this light must also escape more easily as the distance between the carbons increases. The light emitted by the red parts of the carbons is quite small; but such as it is, I have found that it

* Abstract of a Paper read before the International Electricity Congress at Paris.

Digitized by Google

increases on lengthening the arc, since the lengths of these red portions increases. The light emitted by the vaporous arc must also increase with the length of the arc, since its surface of emission must increase at the same time. Thus the light from each source increases with the length of the arc, and the curve which connects the mean spherical candle-power with this length should, therefore, take the form already shown in Fig. 3. How is it then that the shape of the curve is entirely different when it is determined experimentally? How is it that, instead of increasing continuously, the candle-power shows two maximum and one minimum points?

Let us first seek the reason of the first maximum and the minimum. For this we must consider again the shielding effect of the negative carbon. Up to the present, we have not taken account of the different forms which this carbon assumes according to the magnitude of the current and the length of the arc. Now I showed in 1895, that the shapes of the two carbons change very much when these two variables are changed, and that there even grows a sort of very sharp supplementary point at the extremity of the negative carbon with large currents and short arcs, this point disappearing entirely when the arc is lengthened. Fig. 4 gives four reproductions of the arc and the carbons, which show clearly the difference in shape of the negative carbon with arcs of the same length but different currents. The two to the left are arcs of 1mm. and 2mm. respectively with a current of 6 amperes, and the two to the right are arcs of the same lengths, with a current of 28 amperes. The supplementary point is not seen at all in the first two; but is very distinct in the 2mm. arc to the right, and it is seen still more clearly in the 1mm. arc. It is, above all, the distance between the circle of attachment of this point and the mouth of the crater which determines the amount of crater light which can pass the negative carbon, for the point itself does not stop much of the light. Now the distance between this circle of attachment and the crater in the two 28-ampere arcs is about equal, and when we consider that the whole extremity of the negative carbon is longer and thinner for the 1mm. arc than for the 2mm. arc, we find sufficient reason for the candle-power of the former to be larger, or at least as large as that of the latter.

To sum up, on separating the carbons of a large current arc, the amount of crater light which passes the negative carbon is determined by two opposing tendencies. The increase of distance between the carbons tends to increase the candle-power, but the consequent blunting of the extremity of the negative carbon tends to diminish it. When, in increasing the length of the arc with a constant current, the first tendency predominates, the candle-power increases; when the two effects balance one another the candle-power remains constant, and when the second tendency has the upper hand the candle-power diminishes. The first is what took place with the arcs of 1 mm. and less and the second when the carbons were about 2 mm. apart in the experiments of Prof. Ayrton and M. Blondel.

It would, perhaps, hardly be worth while giving so much attention to the possibility of obtaining more light with a quite short arc than with a longer one, were it not for the following very practical consequences: The difference of potential between the carbons at constant current is less with small arc lengths than with great. The power expended in the short arc is, therefore, less than in the long arc. Thus, with the carbons and the currents of which we are speaking, the arc about 1mm. long gives more light with less consumption of power than an arc of about 2mm. long, i.e., the smaller arc not only gives more light but has actually a better efficiency. Not only that, but I showed in 1896 that the ratio of the power expended in the arc to the power developed by the dynamo increases on diminishing the distance between the carbons at constant current; thus the ratio of candle-power to power developed by the dynamo is also greater with a large current for a 1mm. arc than for a 2mm. arc. Therefore, with large constant currents the short arc with the slender negative carbon has every advantage over an arc a little longer but with a blunter negative; not only does it give more light but it is more efficient.

Let us see if it gives a better efficiency not only than arcs a little longer but also than arcs of every length with the same current. From the point of view of economy two things are essential in the arc. First, it is necessary that the greatest possible quantity of energy supplied to the arc be converted into light, and secondly that the largest possible proportion of this light be utilised. With regard to the first consideration, I have shown elsewhere that the power given to an arc l mm. long between solid carbons of 11mm. and 9mm. diameter with a current of A amperes is $[(38{\cdot}88+2{\cdot}07l)A+11{\cdot}66+10{\cdot}54l]$ watts. Of this power, as I showed at Bristol in 1898, $(38{\cdot}88A+11{\cdot}66+3{\cdot}1l)$ watts are expended at the junction of the two carbons with the arc vapour, and $(2{\cdot}07A+7{\cdot}44)l$ watts are expended in the arc vapour itself. Thus, for every increase of 1mm. in the length of arc there is an increase

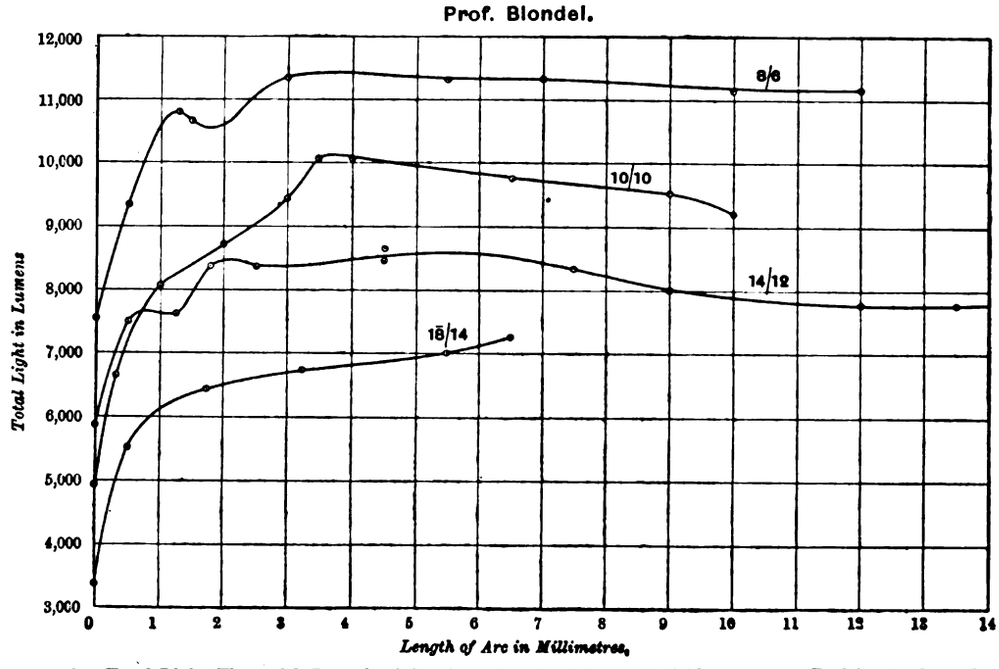

FIG. 2.—Curves connecting Total Light Flux with Length of Arc for a Constant Current of 10 amperes. Positive Carbons Cored. Negative solid.

of 3·1 watts only in the power actually supplied to the junction of the crater with the arc (for the term $3{\cdot}1l$ belongs to the positive carbon alone), and an increase of $(2{\cdot}07A+7{\cdot}44)$ watts in the power expended in the arc vapour. With a continuous current of 10 amperes, for instance, the increase of power required at the crater for each elongation of 1mm. in the length of arc is only 3 watts; while the vaporous arc, which only contributes a minute fraction of the entire light, requires 28 watts. It is therefore evident that the most economical method of converting the power into light is to employ as short an arc as possible. A short arc therefore, no matter what is the current, is doubly economical so far as the production of light is concerned. It is economical, as I have already pointed out, because it utilises a large part of the power developed by the dynamo, and it is economical because it transforms a large part of that power into light.

However, the virtues of the very short arc of 1mm. or thereabouts have not, up to the present, been recognised. They have been obscured, like the light of the crater, by the negative carbon. What is the good of all this economy in the creation of light if, after all, it is hidden under a bushel? It is here that the very short arc with large currents comes in. In this arc the light created is not shut in between the two carbons; the slender point of the negative allows more light to pass than if the arc were two or three times as long, but had a blunter negative. Not only, therefore, does a short arc transform the greatest possible part of the power of the dynamo into light, but if it is also a large-current arc it permits us to utilise the greatest possible quantity of this light. In short, the very short arc with large currents combines all the conditions necessary for the greatest economy.

Digitized by Google

To prove that this is not mere theory, we will turn again to that rich mine of experiment, the researches of M. Blondel. In his investigation with continuous currents, M. Blondel employed, among others, four pairs of carbons of the same quality, the positive being cored and the negative solid, the diameters being 18—14, 14—12, 10—10 and 8—6. I have plotted, from the figures which he has given in his tables for each of these pairs of carbons, curves which connect the efficiency and length of the arc for arcs of 0mm. to 10mm. at a constant current of 10 amperes. For one pair (10—10), the maximum efficiency was badly defined, but for the other three the efficiency was a maximum with arcs of 1mm., 0·7mm. and 1·25mm. respectively. Thus, even with carbons as large as 18mm. and 14mm. and currents as small as 10 amperes, the most economical arc is as short as about 1mm.

There is one other consideration which tends to economy with short arcs: it is that the negative carbon, if not both carbons, is consumed more slowly than in a long arc for the same current. There are two reasons for this. First, the short arc extends further along the negative carbon and protects it better from the air. Secondly, the carbon thrown off from the positive, instead of distributing itself and being dissipated, remains on the negative point and forms there, I think, that supplementary point which is the particular cause of economy in short arcs with large currents.

The sharpening of the negative carbons with large currents and a short arc has thus a very practical value. It allows us to approach the ideal conditions for the arc as regards economy. These ideal conditions are: (1) That the distance between the carbons be zero, and (2) That the extremity of the carbon be infinitely thin. It is true that this ideal can never be realised, but it is always well to recognise the ideal for it points the way to progress. The most evident progress in this case would be: First, to employ with given

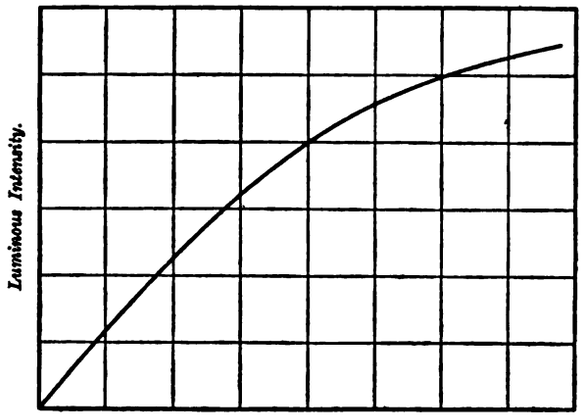

Fig. 3.

carbons, the shortest arcs and the largest currents possible, without approaching too near to the hissing point. Secondly, to find a negative carbon which, when burning in the arc shall have an extremity even longer and thinner than the carbons employed at present and which, nevertheless, shall burn much more slowly.

We now come to the second point of maximum candle-power in the curves which connect the candle-power with the length of arc (Figs. 1 and 2). This point, as we have already seen, depends neither on the changes in the shapes of the carbons nor on variations in the four minor sources of light. It is, therefore, to the amount of light received from the crater that we must attribute the variation of light which produces the second diminution of candle-power after a certain length of arc. This diminution differs from the first of which we have spoken, as it occurs with all currents, whatever their magnitude. The light received from the crater can only depend on three circumstances: First, the area of the crater; secondly, its intrinsic brilliancy; and thirdly, the opposition offered to the passage of the light by the negative carbon or other causes. I have already mentioned that the area of the crater increases with the distance between the carbons, and that Sir William Abney found the intrinsic brilliancy absolutely constant. It is true that in one of his experiments M. Blondel thought he found that the maximum brilliancy of the crater changed from 163 *bougies décimales* per square millimetre with a current of 5 amperes to 210 *bougies décimales* with a current of 25 amperes; but, as he remarked at the time, this kind of measurement is very difficult to make, on account of the continual change in the position of the crater, so that one must not rely too much on this observation. Besides, even if the measurement had been exact, it is impossible to believe that the variations observed denoted changes in the intrinsic brilliancy of the crater. For if this brilliancy is not constant the temperature of the crater cannot be constant either. Now the experiments of Rossetti, Nakano, and several other observers, and, above all, those of Violle, prove conclusively that the temperature of the crater is absolutely constant at atmospheric pressure. Therefore, it is to no real variation in the brilliancy of the crater that these apparent variations can be attributed, and, in consequence, it cannot be a diminution in the intrinsic brilliancy of the crater that can be the cause of the diminution of the candle-power of the arc after a certain length. There only remains one way of explaining this diminution. It is by some sort of screening other than that caused by the negative carbon, for this, as we have seen, screens the light of the crater less and less after a length of arc of 3mm. We must, therefore, see if we can find something else that screens the light of the crater.

Turning over in my mind all the causes which could contribute to such a screening action, it occurred to me that, although the light *emitted* per square millimetre of the crater was necessarily constant on account of the constancy of its temperature, the same did not necessarily hold for the quantity of light which would strike the eye or the screen of the photometer. For in passing from the crater to the eye, the light is obliged to cross a region full of a substance which is called carbon vapour. Now, if this substance could, for instance, absorb a perceptible quantity of light, then lengthening the arc would increase the quantity of absorbent material which the rays would have to traverse, and hence would diminish the amount of light emerging from it. It may be objected that there is never sufficient vapour to absorb the quantity of light necessary

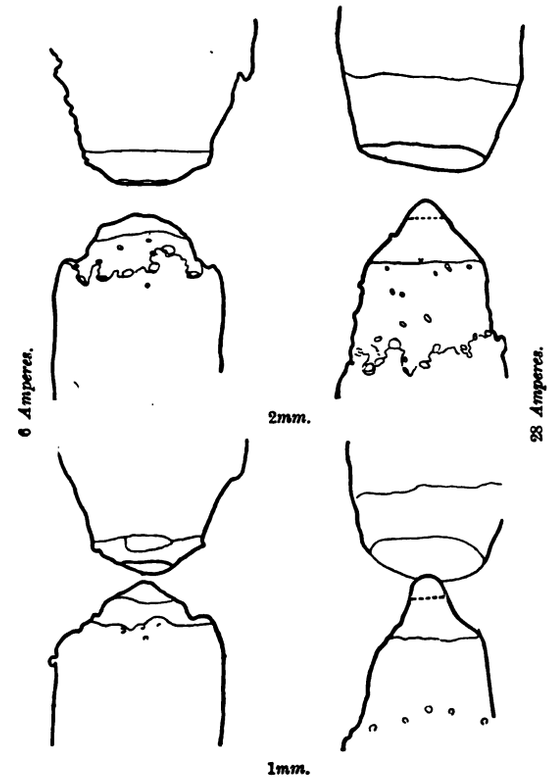

Fig. 4.—Diagrams of Carbons with Arcs of 1mm. and 2mm. and Currents of 6 amperes and 28 amperes.
Carbons: Positive, 13mm. cored; Negative, 11mm. solid.

to cause the diminution of candle-power in question. Perhaps not, if it is vapour pure and simple. But far from this being the case, as long ago as 1822 Silliman, editor of the paper bearing his name, observed that there is always a continuous current of solid particles of carbon rejected from the positive towards the negative pole; a fact frequently observed since. In 1897, also, Herzfeld, as the result of a beautiful experiment, succeeded in attracting these particles out of the arc on to a well-insulated plate charged at a high potential, and placed at 8cm. from the arc. We see, therefore, that the arc cannot be composed of vapour only; on the contrary, it must have a very complex composition of vapour, gas and solid particles of carbon. Now, I argued that the solid particles since they are heated to a white heat must certainly reflect part of each ray that strikes them, and they refract and absorb other parts of the ray. In consequence this arc, which is termed gaseous, but is not at all purely gaseous, must throw a shadow. Hence, on passing the light of a crater of an arc through another arc on to a screen, the shadow of the second arc must be cast on the screen.

To verify this, Mr. Mather was kind enough to try the experiment for me, and unquestionably the shadow of the second arc was defined very clearly on the screen. It had the form shown in Fig. 5, which is copied from a photograph taken for me by Messrs. Fithian and Denny, two students of the Central Technical College. It is very difficult to photograph such a changing shadow, and so delicate

Digitized by Google

a one, between dark carbons, and unhappily the tints of the shadow are lost, but one sees distinctly its form and the line of light which surrounds it. Mr. Mather was the first to observe this line, and immediately recognised its significance. It is that the arc is a lens which thus refracts the light that traverses it. From the form of this lens it may be deduced that the arc is less dense than the hot air which surrounds it, for it has a double convex cylindrical form, and if it were denser than the air with this shape its shadow would have a white spot of light *at the centre*. The arc behaves, therefore, as a negative lens. If the arc only refracted the light of the crater, or even if it refracted and reflected it only, this alone would not necessitate a part of the light being lost. It would only change the *disposition* of the light without changing its quantity. It is true that, in refracting the light of the crater, the arc bends into the negative carbon some rays, which otherwise would reach the eye, but after a geometrical examination of several images of arcs of different lengths with the same current, I have convinced myself that this absorption, which is always fairly small, actually diminishes as the arc is lengthened. Thus, so far as this refraction is concerned, the luminous intensity of the arc must *increase* on separating the carbons more and more. No, we have not to do with absorption in the carbons, but with an actual loss of light by absorption in the space between the carbons. For let us see what must happen when the light of the crater traverses the space full of vapour, gas, and solid particles of carbon, which is called the arc vapour.

It may be admitted that the light of the crater is partly reflected and partly absorbed by each particle of solid carbon which it meets. Hence, no ray which meets a particle of the solid carbon will pass straight through the arc. Some rays will, perhaps, not meet any at all, others will only meet a few particles, while others again will be

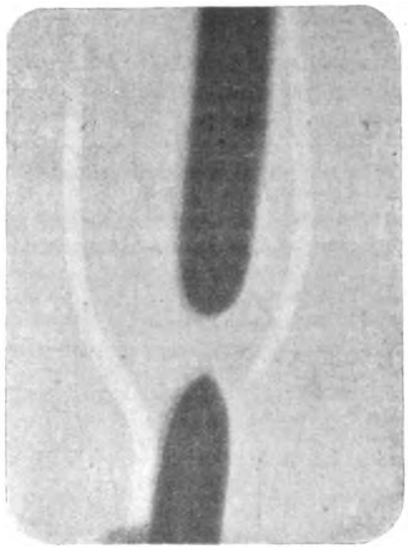

FIG. 5.—Shadow of the Arc.

reflected from particle to particle in and out and up and down, and at each reflection a part of their light will be absorbed. The more particles there are in the arc, the more the light of the crater will be absorbed. Thus, if there are more of these particles in a long arc than in a short one, this is all that is necessary for the light intensity of the arc to diminish after certain lengths. For on separating the carbons (when there is no longer a supplementary point on the negative) there will be an increase in the candle-power on account of the increase of the distance between the carbons and a diminution on account of the absorption of the light from the crater by the solid particles in the arc.

It only remains to show that there are more solid particles in a long arc than in a short one, and this I will endeavour to do. The carbon is evaporated at the surface of the crater. Everyone is in agreement about this, but how is it that everybody also agrees that it remains in this state of vapour even at a distance of 1cm. or more from the crater? Water vapour when it leaves the spout of a kettle only continues as vapour for a short distance, and then becomes mist. What prevents carbon vapour from being transformed into mist at a short—a very short—distance from the crater? For there is much more difference between the temperature of carbon vapour and the air which surrounds the arc than there is between the temperature of the water vapour and the air which surrounds the spout of a kettle. It is true that the current, in flowing through the arc, must heat it, but it heats it equally over its whole length; while the air must cool to a much greater extent that part of the vapour which is far from the seat of vaporisation (the crater) than that which is nearer to it. Thus the arc must have a falling curve of temperature which diminishes in passing from the crater to the negative carbon.

There is a little experiment which I have often made, which shows clearly that the temperature of the arc quite near to the crater is higher than elsewhere. On putting the extremity of a very thin carbon pencil in the arc near the crater, one can bend this carbon pencil sufficiently to make a perceptible angle by pressing it against the positive carbon; but there is no other part of the arc in which this can be done. If, for instance, two of the little carbons be introduced into the arc and pressed one against the other, it is impossible to bend them, and it is the same on pressing one of these carbons against the negative, it will not deflect the least little bit. That shows, I think, that quite near to the crater the arc is so hot that it can soften the carbons, but that further off it is too cold to do this.

Thus it is more than probable that the carbon vapour on leaving the crater acts in exactly the same way as water vapour leaving the spout of a kettle. For a very short distance it remains in the state of vapour, and further on it becomes carbon mist and cools more and more as it gets further from the crater. If the layer of vapour that is spread over the crater is very thin, and if it has (as all pure vapours have) a large specific resistance, the resistance of this layer might be great enough to explain the greater part of the difference of potential—the back E.M.F., as it is called—which always exists between the positive carbon and the arc. The mist, on the contrary, which would be mixed with the burning gases, would have a relatively low resistance, so that the resistance of the gaseous arc would be relatively small; which is what is found in practice. In any case, if the carbon vapour becomes mist at a short distance from the crater (and the solid particles of carbon thrown off by the positive would assist this transformation), then by increasing the length of the arc the quantity of this mist would be increased, and the light of the crater would traverse more of the absorbent material; so that the amount of this light that was absorbed by the arc would increase with the length of the arc.

(To be concluded.)

RECENT TRAMWAY CONSTRUCTION, WITH SPECIAL REFERENCE TO THE DEMERBE SYSTEM.*

BY WILLIAM DAWSON.

It is about 35 years since the introduction of tramways into the large towns of Europe, and an account of the changes and developments which have been made in this means of transport would be very interesting from an historical point of view, but of little technical or industrial interest. The principles of construction, the different systems formerly in use, and the mode of traction have all been revolutionised in the comparatively short time which has passed since the introduction of tramways into this country, so that there is little to learn from the past. It would take up too much time to enumerate and investigate all the systems of tramway construction which were successively tried when tramways were generally worked by horse traction, and which have now given place to other methods more suitable for mechanical or electric traction. The first tramrails were laid on either longitudinal or transverse wooden sleepers, but it was found that the wood soon rotted. The sleepers were therefore discarded, and experiments made with tramways constructed entirely of metal. The Vignoles rail was adapted for this purpose, and, finally, rails of the Brocca (or girder) and the Demerbe (or trough) type were manufactured.

The Brocca rail was aftewards adopted in Germany and England under the name of the Phœnix or girder rail. This form of rail was a modification of the Vignoles rail, as the foot or bottom flange was merely widened and laid direct on the soil or on a bed of concrete. It is now generally adopted throughout England, but in my opinion has not proved a success. When animal traction only was used, very little attention was given to the fishing of the joints of the rails, but on the introduction of steam and electric traction it was soon found that the joints were unable to stand the increased strain. The fish-plates were increased in length and thickness until in some cases they were 3ft. long and 1in. thick; eight 1in. fish-bolts were used, sole-plates were placed under the ends of the rails, narrow steel strips were placed on the top of the bottom flanges of the rails at the joints, and the whole securely bolted together with six ⅞in. bolts. The joints still worked loose, and it is now recognised that all it is possible to do in this direction is insufficient to make a perfect joint. In Germany, the ends of the rails were cut obliquely, afterwards they were halved on to each other, or the ends were notched, and a fish-plate placed in the recess. All possible methods have been tried to prevent the joints working loose, and numerous patents have been

* Paper read before Section G of the British Association at Bradford.

Digitized by Google

obtained for different ways of strengthening the fishing—all costly, and not completely satisfactory in spite of the extra outlay. The girder rail joint is undoubtedly defective, and the trouble which arises is to be attributed partly to the fact that the top and bottom of the fish-plates corrode, as also does the under side of the head of the rail. The fish-plates then occupy a less space, and are less in depth than they were when new. The head and bottom flange of the rail is not firmly gripped by the fish-plates, and as their proper work is to maintain the level of the ends of the rails under the action of unequally distributed forces, the joint soon becomes loose. It is not, therefore, surprising that the consideration of the best means of

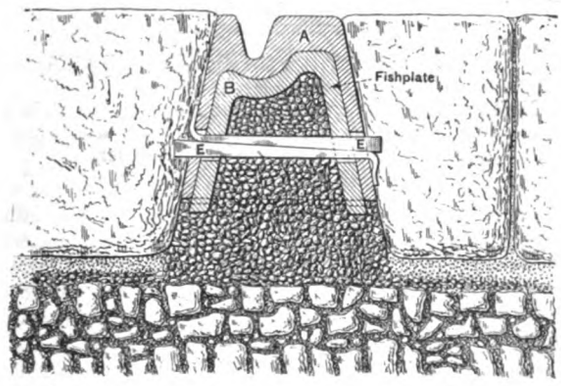

FIG. 1.—Section of the Rail with Fishplate.

fishing the joints of tramways has brought to the surface numerous, complicated, and often very remarkable methods of dealing with this branch of tramway construction.

The Demerbe system of tramway differs entirely from all other types, and possesses in many ways some of the chief attributes of a perfect tramway. It consists of a hollow trough rail (A, Fig. 1), and the fishplate (B, Fig. 1) is placed inside under the ends of the rails, and exactly fits its contour, the point of application being immediately under the head of the rail. When this system was first introduced the fishplate was pressed into the rail by means of bolts, but it was soon found that this was not satistactory, and cotters (E, Fig. 1) were used. As the holes in the fishplates and rails are cut at different depths, when the cotters are driven in the fishplate is forced close up to the underside of the rail. The ends of the cotters are then clinched against the side of the rail, and are thus fixed and prevented by any possibility from working loose. The rail when laid in position in the carriage-way is completely filled, by means of specially-designed tools, with concrete composed of four parts of ¼in. unscreened granite shingle to one part of Portland cement. The tie bars (G, Figs. 2 and 3) used in the Demerbe system are flat, and the use of screw ends, nuts, and bolts is avoided. The rail is inserted into two oblique grooves, one of which is cut so as to exactly fit the outer side of the rail, whilst the other is wider, so as to facilitate the introduction of the inner side of the rail. In the space which is left a wedge of soft steel (D, Fig. 3), a little smaller than the opening it has to fit, is inserted and driven up. This arrangement of the tie bar enables the rails to be fixed to gauge with almost mathematical exactitude.

In England, as a rule, a concrete foundation is laid the whole width of the carriage-way to receive the paving, and when the Demerbe rail is filled with concrete in the manner above described it becomes attached to the concrete foundation, and is practically part and parcel of the carriage-way. It is, therefore, capable not only of withstanding the strains caused by the cars, but also all the strains and vibrations caused by the ordinary vehicular traffic, without any loosening of the joints or displacement of the paving. The girder rail is laid direct on the concrete foundation, and the oblique strains brought to bear on the head of the rail by the tramcars and other traffic causes the extremities of the foot or bottom flange of the rail to have a tendency to crush the concrete, and so allows the rail to oscillate on its base. As soon as the rail is subjected to the least movement or vibration, a narrow fissure is produced alongside, which increases in width as the foot become more movable. Water penetrates between the paving and the rail, and in frosty weather the paving is uplifted. The joint of the rails is also partly responsible for these defects, as the water finds an early passage between the rails and fishplates.

It is necessary to take into account another factor which contributes to the grinding away or pulverisation of the concrete. The ends of the rails rest on a sole plate, which is intended to maintain the ends of the rails at one level. When the cars pass over the track the shock is harder at the joint than on the rest of the rail, where the movement caused by the car is more elastic, because the sole-plate and the concrete do not support the rail with the same rigidity, and the rails become dented at the joints even when they are in perfect alignment. It follows then that the same rigidity should exist at the middle of the rail as at the joint. In the Demerbe system this is so, as the concrete becomes perfectly attached to the rail, and the ridge of armoured concrete becomes part and parcel of the foundation itself. The same resistance is offered to the weight of vehicles for the whole length of the rail, no part being found to be weaker or more elastic than another.

In 1894 a short experimental length of the Demerbe rail was laid in Leeds-road, Bradford, end to end with a similar length of girder rail. Both portions have been subjected to a 5-minute service of steam locomotive cars since that time. About three weeks ago a Demerbe rail was removed, in the presence of the Tramway committee, to ascertain its condition. The rail, joint, and gauge were found to be in every way perfect, and it was only after repeated blows with heavy hammers that the rail could be detached from the concrete foundation, and when raised it dragged up with it part of the foundation. No money whatever has been spent in repairing

this portion of Demerbe tramway, but the adjoining portion of girder rail has been several times repaired during the six years it has been laid down. The setts used alongside the Demerbe rail are splayed to fit the sides of the rail, and laid directly against it, the rail thus serving as a support for the paving: and there is no tendency either for the setts to rise or fall as is the case with the girder rail. There are in Bradford 40½ miles of tramways, of which 36½ miles are laid on the girder system, with rails weighing 105lb. per yard, and fish-plates weighing 80lb. per pair. There are 4 miles of Demerbe tramway, constructed of rails weighing 70½lb. per yard, and fishplates weighing 51½lb. each, and the Corporation have, further, in course of construction an additional 10½ miles of tramway, which they are putting down on the Demerbe system.

The detailed cost per yard of single track on the two systems, based on the price of materials delivered at Bradford, is as follows:—

Demerbe System.	s.	d.
Rails	10	7·9
Fish-plates	0	9·4
Tie-bars	1	6·8
Wedges	0	1·4
Cotters	0	7·1
Track labour, including curve	2	6·0
Rails, &c., carting	0	1·1
Packing rails (labour)	0	11·0
Half-inch unscreened granite shingle	1	0·0
Cement	0	11·5
Team labour	0	3·2
	19	5·4

Girder System.	£	s.	d.
Rails	0	15	11·2
Fish-plates	0	1	8·8
Marshall's patent joints	0	0	9·9
Bolts and nuts	0	0	5·4
Sole-plates	0	1	0·3
Tie-bars	0	0	2·8
Unscreened granite shingle	0	0	4·0
Cement	0	0	5·1
Labour (packing rails)	0	0	3·6
Road scrapings (for plastering rail)	0	0	0·6
Track labour	0	1	3·0
Team labour	0	0	1·6
Sole-plates, punching	0	0	1·9
Blacksmiths' work	0	0	1·3
Repairs to punches	0	0	1·9
	£1	3	1·4

Although it will be seen from the foregoing tables that the first cost of the Demerbe track is cheaper than the girder track, this point is not the most important. There is the cost of maintenance to consider, and judging from the condition of the Demerbe track in Leeds-road after six years' wear and tear, it does not appear that any repairs will ever be necessary during the life of the rail once it is properly laid. This life I should estimate to be about 20 years, whilst the girder rail has to be renewed in 16 years.

The opponents of the Demerbe system when they compare these rails with the girder type, state that the latter rail when laid on two supports will carry a heavier load than the Demerbe rail under the same conditions. This is quite true, but the Demerbe rail does not act, nor is it intended to act, as a girder. It is supported throughout its entire length by a ridge of concrete, and the rail merely acts as a metallic covering.

The advantages of the Demerbe system of tramway over other systems may be summarised as follows: (1) The system is simple, being composed of very few parts. It is also cheaper, and can be laid more quickly than the girder system. (2) The rail and concrete resist the heaviest loads without displacement, depression, or other alteration of the track. (3) The cost of maintenance of rails and paving is reduced to a minimum. (4) The tie-bars are constructed without rivets or nuts. No punching or drilling of the rails is therefore necessary, as the tie-bars can be fixed to any part of the rail by means of the slots. (5) Curves of quick radii are made at the works, and are laid as quickly as straight track. (6) The concrete support effectually prevents water finding its way under the rail.

Having regard to the very large sums spent annually on tramways maintenance, it is of the highest importance that lines should be constructed on a system which promises the longest working life, with a minimum of cost for repairs. The writer after a considerable experience in tramway construction and maintenance, has no hesitation whatever in affirming that the Demerbe system possesses points which place it far before the girder and other systems, and he can confidently commend it to the consideration of those having in any way to do with the development and extension of facilities for public transport by means of tramways. And as Bradford is the only city in the United Kingdom which has tested the Demerbe system, it is perhaps not unfitting that this Paper should form a contribution to the British Association when it holds its meeting in that city.

ELECTRICITY WORKS ACCOUNTS.

Newcastle-upon-Tyne Electric Supply Co. (Ltd.)

Although there has been somewhat of a retrogression in the results shown by the accounts of this company they are, in all respects, most excellent. Owing to a slight increase in the management and property charges the total costs have also risen, although the works costs have dropped perceptibly. All the several items and the aggregate costs are well below the average of 1898. As a result of the decrease in the total receipts per unit coupled with the increased costs the working profit has suffered, it representing 8·38 per cent. of the mean capital in 1899 as compared with 9·05 per cent. in 1898.

As in 1898 there was a special expenditure on dynamo reconstruction. In that year the amount thus spent was £1,295, last year it was £737. Another item of unusual expenditure was that of £876 incurred in opposing the Newcastle-on-Tyne (Corporation) Tramways Improvement Bill. These amounts have been kept from entering the costs columns in our analysis.

The business progresses well. The lamp connections last year raised the total equivalent in 8 c.p. lamps from 53,500 to 64,156—an advance of nearly 20 per cent. Similarly, the output rose to 967,098 units sold, or 20·3 per cent. Unfortunately the load factor, which was 10·75 per cent. in 1898 has fallen to 10·58 per cent.

Aberdeen Municipal Electric Supply Works.

In our second table we give a summary of the accounts of the Aberdeen undertaking for the two periods—one of seven months and the other of twelve months—which ended respectively July 31, 1899, and July 31, 1900. The results of the working during the latter period affords a striking comparison with the operations of 1898, while the costs figures attained last year are highly satisfactory, even considered in relation with the high load factor of 12·6 per cent., which obtained during the period. Among the generating costs the fuel item represents the average of 1898 under similar conditions. The remaining three items are all much below those averages. The chief seat of the improvement in the aggregate costs as compared with those of 1898 is in the management and property charges. This collective item has dropped nearly 0·28d., and at its present figure of 0·43d. presents an excellent result.

Turning to the business done it will be noticed that the output has made the splendid advance of 105 per cent., or from 412,353 to 846,012 units sold. Of the total, 15·5 per cent. of the output sold was supplied to the tramways and 7·64 per cent. for public lighting. It is no doubt due to the acquisition of the tramways as a customer that the very beneficial rise in load-factor is due. In 1898 this factor was 9·23 per cent.; last year it had risen to 12·62 per cent. An examination of the figures near the foot of our analysis will show how this improved load has been the means of increasing the earning power of the generating plant installed in the station. In 1898 the revenue and expenditure per kilowatt of plant capacity were respectively £3. 7s. 7d. and £7. 12s. 5d. Last year the respective figures were £4. 12s. and £12. 1s. The scheme of payment for the tramway supply is that it be paid for at cost price, inclusive of interest and sinking fund charges. Exclusive of the tramways, the equivalent in 8 c.p. lamps connected during the year ended at June 31 last was—in arcs 1,830, in glow lamps 9,529, and in motors 18,709, being a total (exclusive of the tramways) of 30,068 8 c.p. lamps. The total number of motors now on the mains is 63, representing 198 H P

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d.; post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free 2s. 3d. each; strong cloth 2s. 6d., post free 2s. 9d. each. Single Primers 2d., post free 2½d.

WIRELESS TELEGRAPHY: SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES. By Dr. O. J. LODGE. New Edition. Price 5s. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, ELECTRIC TRACTION, TELEGRAPHS, TELEPHONES, &c. A. C. CURTIS-HAYWARD, B.A. To January, 1900. Price 3s. 6d., post free.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By FRANCIS JEHL. Price 10s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

THE ELECTRIC ARC.—By Mrs. AYRTON. This work is in the press and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. WADE. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. RAPHAEL. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

THE TELEPHONE.—By DANE SINCLAIR and F. C. RAPHAEL.

SPECIAL NOTICES.

NOW READY.—Vol. XLIV. of "THE ELECTRICIAN" (960 pages) bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of "THE ELECTRICIAN" (1878-1900) can now be supplied. These sets are very scarce, and early application should be made

EFFICIENCY OF THE CONTINUOUS-CURRENT ARC.

In Mrs. AYRTON's Paper on "The Light Emitted by the Continuous Current Arc," read before the International Electricity Congress at Paris, we have a record of an investigation of high practical importance as well as of scientific interest. Taking up a discovery of Profs. AYRTON and CARHART, published at Chicago in 1893, Mrs. AYRTON, in the present Paper, seeks the cause of the result established by them—viz., that for a given constant current, so long as it is not too small, as the arc length is increased by the separation of the carbons from contact, the light emitted rises first to a maximum, then falls to a minimum, and finally rises again to a second maximum value. It is evident that the centre of practical interest and importance lies in the first maximum point, since, if this point is sufficiently high in respect to the second maximum and also in relation with the rate of increase of power taken up in the arc with increase in its length, this first point represents the condition of maximum efficiency of light radiation. Although Mrs. AYRTON satisfied herself by experiment that there existed the first maximum and minimum points, and has thereby confirmed some of the results of Profs. AYRTON and CARHART and M. BLONDEL to the same effect, she appears to have relied on the valuable data supplied by experiments of the last-mentioned of these three investigators in arriving at the conclusion that the point of maximum efficiency of light radiation at the arc is the first and not the second maximum point. It would have been most interesting from a practical point of view had Mrs. AYRTON published the four curves connecting the ratio of the mean spherical candle power to electrical power taken up in the arc with the various lengths of arc. Mrs. AYRTON tells us that even with carbons as large as 18mm. and 14mm. and currents as low as 10 amperes the most economical arc is as short as one millimetre at least for the cored positive and solid negative carbons used by M. BLONDEL. It is now some years since Mrs. AYRTON, in her discussion of the stability of the arc, indicated that short arcs and large currents were the conditions for obtaining the highest ratio of available power at the arc to that developed in the supplying dynamo or taken off a constant-pressure service. We now learn that short arcs and large currents are also indicated when a maximum available light emission for a certain power consumption in the arc is in view—at any rate, with cored positive and solid negative carbons—and

Digitized by Google

that there is the additional advantage of a smaller carbon consumption with the shorter arcs.

Unfortunately, in attempting to realise in actual practice the ideal conditions enunciated by Mrs. AYRTON, a certain amount of difficulty is met with as regards the steadiness of the light. The closer we fulfil the ideal conditions the closer we have to work to the unstable condition of hissing. Further, with a short arc the proportionate variation in its length with a poor feed action is much greater than in a long arc. On the other hand, given a good feed, short arcs are in themselves the steadier. In public arc lighting, perhaps, these conditions for maximum efficiency have been worked to, on the whole, as far as possible, but it is interesting to note that the bulk of private arc lighting is carried out under conditions far removed from those conducing to economy. Perhaps the chief reason for this is that the low elevation at which lamps of this class are installed necessitates the use of many lamps of small capacity in order to secure passably uniform distribution of light. Take the case of enclosed arc lamps. The reason for their very extended use may be found in their saving of carbon and attendance,—items which represent a large proportion of the total cost of the maintenance of arc lamps. While keeping in mind this characteristic of enclosed arcs, it is interesting to compare the arc conditions in this type of lamp with the conditions for efficiency set forth by Mrs. AYRTON. As compared with the one millimetre or slightly less length of arc in the ideal lamp, power is expended in the enclosed lamp on something like 12mm. length of arc. This length to some extent secures the light from being obscured by the lower carbon, yet even this advantage is discounted owing to the very blunt burning of the negative as well as the positive carbon end. Further, owing to the necessary employment of a comparatively small current—generally half that used in an open lamp of similar capacity—the ratio of the power consumed in the arc to that taken from a constant-pressure circuit is much the lowest in the case of the enclosed arc lamp.

The latter part of Mrs. AYRTON's Paper, in which an explanation is sought of the observed fall of the total light from the arc after the second maximum value of the light has been passed with increase of arc length, is of less practical importance. This investigation is, however, exceedingly interesting from the point of view of theory. Especially so is the account of the ingenious experiment of throwing a shadow of the arc itself and the resulting evidence of its refracting power. This part of Mrs. AYRTON's researches, together with her deductions from them, is more fully dealt with in a conclusion to her Paper which she has just sent us as we go to press; and we hope to publish this with our comments in a future issue.

STABILITY OF TEMPERATURE IN AN ELECTRIC CONDUCTOR.

BY H. E. WIMPERIS, B.A., WH.SC.

It is well known that the electrical resistance of most metals increases with rise of temperature, the law being nearly linear. This fact suggested to the writer that possible cases of instability of temperature might occur in the case of a conducting wire, along which a constant current flowed. Thus in Fig. 1, AB is a wire of some conducting metal and a constant current is kept flowing between A and B. Consider a small length CD of the wire, and let it be raised (by a flame, for instance) to a higher temperature than the neighbouring portions of the wire; the resistance of CD is increased and therefore the heat generated by the current at that portion will be greater, since the term (current)^2 × resistance is increased, and its temperature will tend to rise still further.

There are two phenomena that tend to oppose this rise of temperature, and they are the increased radiation from the wire and the fact that heat is conducted away through the material of the wire itself.

The latter of these two results can be made of very slight importance by suitably designing the wire. Whether or no the temperature of CD will rise or fall on the flame being removed depends upon which is greater, the increase of heat owing to increase in resistance or the decrease of heat due to increased radiation. It is obvious that similar problems may be examined in which constant voltage is maintained or in which cooling instead of heating occurs. In Fig. 2 temperature and heat change are plotted as co-ordinates; the dotted lines are curves of increase of C^2R plotted with respect to temperature, and the firm lines are curves showing the loss of heat owing to radiation for different

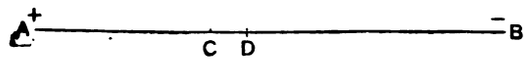

FIG. 1.

temperatures. Thus P and Q would be points of equilibrium, since at P (for example) PM would represent both heat gained from the electric current and heat lost by radiation, and these are shown equal; hence the point P is one of equilibrium. Having established the fact that P and Q are both points of equilibrium, it next becomes necessary to determine whether they are points of stable or unstable equilibrium. Consider the equilibrium at P, and let the temperature increase from OM to ON; then the heat supplied by the current increases from PM to P_2N, and the heat lost by radiation from PM to P_1N. In this case it is evident that the loss of heat is greater than the gain, and the temperature will, therefore, sink to its original value OM; the point P is a point of stable equilibrium.

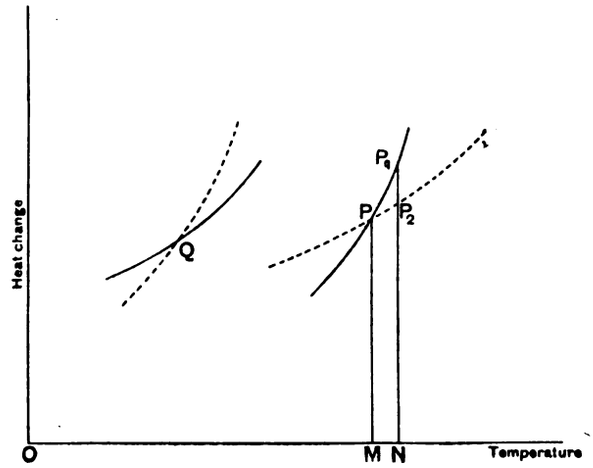

FIG. 2.

A somewhat similar investigation will show that the point Q is a point of unstable equilibrium, since if the temperature increase it tends to increase still more, and if to decrease to decrease still more. The discriminating condition between stability and instability being, which is greater, the slope of the radiation curve or the slope of the resistance curve at the point considered? Finally, it is found that instability is impossible with any metal known. Imagine a wire in equilibrium at a temperature of 200°C., and let the temperature of surrounding objects be 20°C.

The curve for this case is shown in Fig. 3. OA represents the temperature (absolute) of surrounding objects, the dotted line OCPD is the curve of resistance (with respect to temperature), O is the absolute zero of temperature, APB is the curve of heat lost by radiation, OF is the temperature (absolute) of the wire itself. The curve APB is determined from the fact that it must pass through the point A, owing to the fact that the net radiation between bodies at the same temperature (a

Digitized by Google

curious physical fact) is zero, and it must pass through P as P is a point of equilibrium by the hypothesis of the case.

Abundant experiments have shown that the law connecting resistance of a metal with temperature is nearly linear and always passes through or near to the point of absolute zero.

These facts, taken together show that the slope of the radiation curve at P must be greater than the slope of the resistance curve at that point. Hence P is a point of stable equilibrium—it is noteworthy that with surrounding objects at the zero of temperature instability might occur. P would be a position of instability if the radiation curve were the broken one shown at AHPK, but radiation curves are always convex to the axis of temperature. The writer tried a few* experiments with an iron wire before the above form of solution occurred to him; they may be summed up thus: (1) A current was passed through an iron wire so that the wire was just not red hot, a flame was applied and taken away. Red heat spot slowly died away—without current it disappeared very rapidly. (2) Current was cut off and flame applied—flame was removed and red heat spot allowed to die out. Current was again put on after a few seconds interval and red heat spot shone out again and then died away. Current was of same amount as in Experiment 1. (8) Same current was applied and red heat spot obtained by

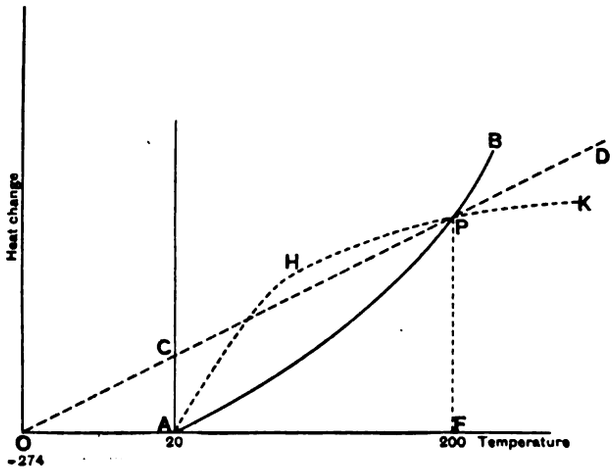

Fig. 3.

flame (flame being then removed). The writer tried to determine whether spot would go to right or left before dying out. It was difficult to determine any motion—if any it was to right. Current was then found to be flowing so as to move spot to right. In this last experiment the motion of the spot (if any really occurred) was due to the fact that owing to difference of temperature in different parts of the wire a thermo-junction effect was set up, helping the current at one end of the heat spot and retarding it at the other end.

ON THE CONSTRUCTION OF DYNAMO-ELECTRIC MACHINES.†

BY MAURICE LEBLANC.

In every dynamo the useful fields are those which pass in the same manner through both the inducing and induced circuits. The other fields, called fields of magnetic leakage, have always a detrimental action. Further, it seems legitimate to say that the best dynamo-electric machine is that in which the magnetic leakage is reduced to a minimum, and, secondly, that in order to reduce such leakage to a minimum, it is necessary to bring the inducing and the induced circuits as near together as possible. To this end it is desirable: (1) To dispose the circuits, the one in notches running in the direction of the length of the internal surface of a ring of laminated iron, the other, in similar notches, running the length of the external surface of another laminated ring concentric with the first, the two rings being separated by a very small air-gap (see Fig. 1). (2) To place the end connections on two concentric cylinders, projecting on both sides of the rings and as near together as the necessities of construction will permit (see Fig. 2). In the case of machines of the induction type in which the field is generated by alternating currents of high frequency, the necessities of the case have resulted in this type of machine being employed. I believe that there would be also the greatest advantage in employing the same design for continuous-current machines and for alternators, and that on these lines machines could be constructed which would be, from every point of view, more economical than those now in use.

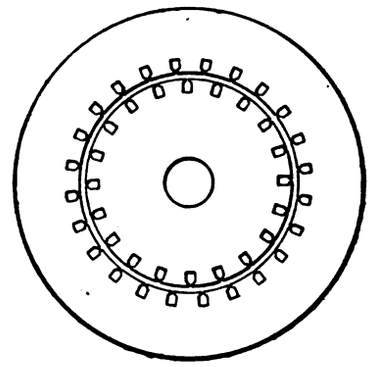

Fig. 1.

In machines of this type, however, the magnetising force developed by the currents in the induced circuits will be of the same order so far as strength is concerned, as that developed by the inducing circuits. It results then that if we wish to obtain currents at constant voltage, which is generally the case, it will be necessary to vary the

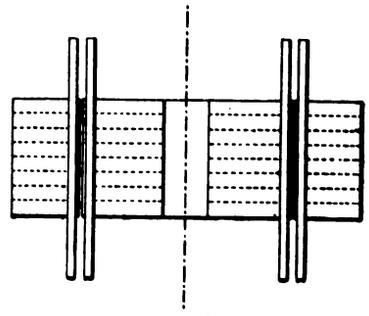

Fig. 2.

strength of the exciting current to a very considerable degree as the load on the machine varies. If this type of machine is to be utilised, as I propose, the variations in the exciting current must be obtained automatically, and by means as simple as those employed in the case of ordinary compound-wound continuous-current machines. We will now see how this result can be obtained in each case.

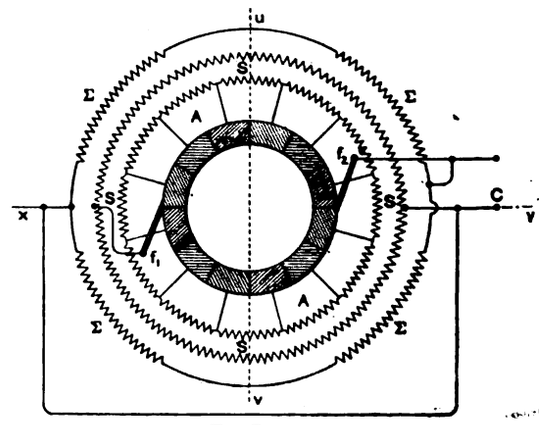

Fig. 3.

I.—Continuous-Current Machines.

The arrangement which it will be best to adopt is shown in Fig. 3. The armature is similar to that of all continuous-current machines in which the connections are placed upon the surface of a cylinder. In the notches in the fixed ring which surrounds it, there are placed: (1) A winding, SS, a reproduction of that on the armature and arranged in series with the armature winding. This winding is so

* The writer is indebted to Mr. Miles Walker, of St. John's College, for suggestion of a graphical in preference to a mathematical treatment.

† Paper read before the International Electricity Congress at Paris.

Digitized by Google

disposed that it develops a magnetising force equal and of opposite sign to that developed by the armature. In these circumstances, the circuit of the machine comprised between the brush f and the terminal c may be considered as having no appreciable self-induction, since it cannot generate any flux other than the magnetic leakage which may occur along the air-gap between the two rings. (2) A winding, arranged as a shunt between the brush F_2 and the terminal c, and which generates a flux in the direction of the diameter vv at right angles to a line joining the brushes. The production of the useful flux is thus less costly in that no other flux is superimposed upon it, and no increase occurs in the reluctance of the magnetic circuits of the machine when the load upon it is increased, as is the case in ordinary machines. An arrangement whereby the reaction of the induced circuit of a continuous-current machine is directly annulled by a magnetising force, produced by a special winding, which is in every direction equal but of opposite sign to that developed by the armature, has already been proposed, I believe, by Messrs. Fischer-Hinnen and Ryan.

When this arrangement has been applied to machines designed in the ordinary way it is true that no great benefit has resulted; but this was natural, seeing that the machines were not adapted for the improvement. This will, however, no longer hold if we employ, as I propose, the carcase of an induction machine in the manufacture of a continuous-current machine. The absence of armature reaction would allow of the length of each pole being increased as far as desired, and of the reduction of the air-gap to the minimum required for mechanical clearance. Machines could then be constructed in which the brushes required no shifting, in which the production of the field cost practically nothing, and in which the weight of copper on the field was practically the same as that on the armature. The machines would then be very light and consequently very economical. Further, as the machines would have no appreciable armature reaction, it would be possible to vary their voltages between the most extreme limits when they were employed as generators, and similarly to vary their speeds when run as motors.

II.—Alternators.

In a continuous-current machine it is necessary for the commutation that the direction of the flux developed in the machine should be constant if one does not wish to have to shift the brushes as the load varies. This condition has no longer to be fulfilled in the case

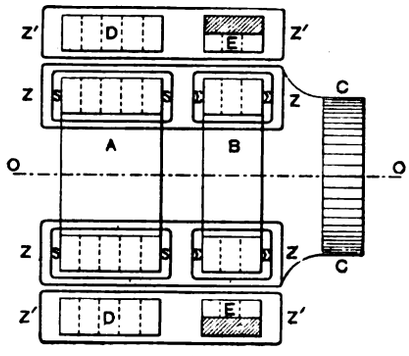

Fig. 4.

of an alternator. It will suffice, therefore, to provide a single exciting circuit, and so to alter the strength of the current in this circuit that, as the load varies, the voltage remains constant.

But as in the preceding case, the chief function of the exciting current will not be to generate the inducing flux, the strength of which the designer will arrange to be as great as possible by the reduction of the air-gap to a minimum and by keeping the iron far from saturation. The principal function will be to develop a magnetising force equal and opposite to that erected by the armature windings. The intensity of the exciting current should therefore be varied considerably with the variations of load on the machine, and the necessary variation ought to be obtained, if possible, automatically.

As a general rule one regulates the voltage of an alternator by varying the field of its exciter. We will now see if it is possible to retain this mode of regulation and to render it automatic: (1) By employing as exciter a continuous-current machine whose field is produced by alternating currents acting through a rectifier or a transformer-rectifier; and (2) by employing more than one circuit to produce the field of this exciter, as in the case of an ordinary compound-wound machine, certain of these circuits being in parallel and the others in series with the armature circuits of the alternator we wish to excite.

In order to fix our ideas, let us assume that we wish to excite a three-phase alternator, and that we employ for the purposes of excitation the special exciter with two poles shown diagrammatically in Fig. 4. Upon the same axis OO are placed the two rings A and B, and around the ring A is wound the circuit S, consisting of three bobbins situated 120deg. apart, S_1, S_2, and S_3. These bobbins are in series with the circuits P_1, P_2, and P_3 of the alternator, through the intermediary of collecting rings and brushes, as shown in Fig. 5. Round the ring B is wound a circuit comprising three bobbins 120deg. apart, Σ_1, Σ_2, and Σ_3. These bobbins are connected as shunts between the three terminals of the alternator I., II., and III., and a neutral point, M, to which are also led the ends of the bobbins S_1, S_2, and S_3. In series with each of the circuits Σ_1, Σ_2, and Σ_3, there is further placed a coil, the self-induction λ of which is adjustable (see Fig. 5).

The rings A and B, with these windings upon them are displaced, relatively to one another, by a certain angle ξ, which will be dealt with later. A continuous-current winding, Z, is then added, which encloses at the same time both rings A and B. This winding terminates in a collector CC (see Fig. 4). Two brushes, at the opposite ends of a diameter, bear upon this collector, from which is obtained the direct current for exciting the field of the alternator.

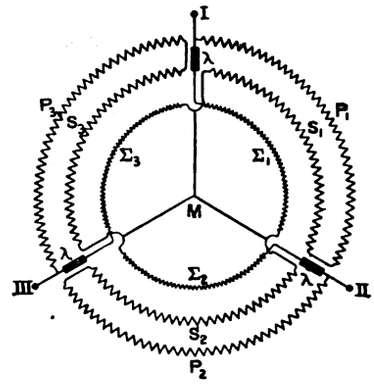

Fig. 5.

The rings A and B rotate in the interior of two iron rings D and E, which serve to complete the magnetic circuits for the fields generated by the windings on A and B. The sections of rings A and D are so proportioned that the magnetic circuit of A is always far from saturation, while the section of E, on the contrary, is such that it is magnetically saturated when the alternator produces its normal voltage. Finally, a winding Z', with the same number of turns as the circuit Z, is given to the rings D and E. This winding covers both rings simultaneously, and through it circulates the current from the collector CC, as is shown by the arrows in Fig. 6. The ends of this winding are so chosen that its magnetising force is equal and opposite to that of the winding Z.

The spindle OO is arranged to rotate in synchronism with that of the alternator, in any suitable manner; and the direction of rotation must be such that the fields produced by the windings S and Σ remain fixed in space. Under these conditions the winding Z will produce a continuous current just as though it were subjected to the action

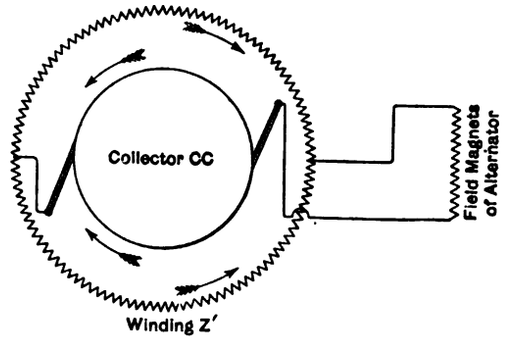

Fig. 6.

of a fixed circuit excited by a direct current. But whatever may be the strength of the current furnished by the winding Z it will produce no appreciable field, owing to its magnetising force being counterbalanced by that of the winding Z'.

I shall now proceed to show that if this exciter is properly dimensioned the alternator which it excites will give a constant voltage, no matter what the load, without the necessity for shifting the brushes of the exciter. As has been said above, if the alternator has been properly designed the resistance of those portions of its magnetic circuit which are of iron will be negligible compared with that of the air-gap, and we may consider its coefficients of self-induction as constant. And the same will hold good of each of the circuits of the winding S of the exciter.

1. *Angle of displacement of the rings A and B.*—Let us designate by r and l the resistance and the coefficient of self-induction of each

Digitized by Google

of the circuits formed by the union in series of one of the armature circuits of the alternator and one of the windings S of the exciter. Let a be the frequency of the generated currents. According to what we have just said, the ratio $\frac{2\pi al}{r}$ will be constant.

Let $\tan\omega=\frac{2\pi al}{r}$ and $\xi=\frac{\pi}{2}-\omega$. The angle ξ thus defined is that through which it will be necessary to displace one of the rings relatively to the other, as has been said above. The ring B should be displaced relatively to A in the direction of the rotation of the rings.

2. *Proportions of the ring A and of the windings S and* Σ.—Let the armature of the alternator be short-circuited, and let the brushes of

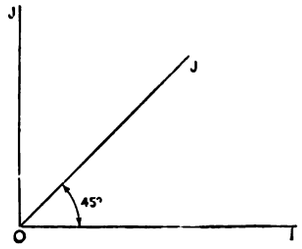

FIG. 7.

the exciter supply current to a resistance equal to that of the exciting circuit of the exciter. Let us then excite this exciter with a continuous current from an outside source. Further, let the machine rotate at its normal speed, and let the brushes be shifted until the current from the exciter brushes is a maximum. Then note the values of the current J furnished by the exciter for different values i of the exciting current. The curve connecting J and i will be a straight line (see Fig. 7). The ring A and the windings S and Z ought to be so arranged that this straight line makes an angle of 45deg. with the line Oi. The necessary adjustment will be facilitated by the introduction of a variable resistance in the field circuit of the alternator.

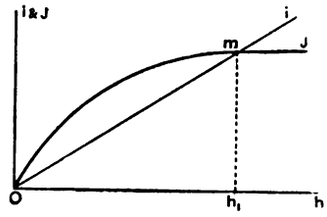

FIG. 8.

3. *Proportions of the ring B and of the winding* Σ.—Let us now open the armature circuits of our alternator, leaving the exciter circuited through the same resistance as before, and let us again rotate the alternator at its normal speed, exciting it from an outside source. The position of the brushes should be the same as in the preceding case. We then measure the strength, J, of the current, and i of the exciting current and the voltage h at the terminals of the alternator. Let the voltage be plotted as abscissæ, and the currents i and J as ordinates (see Fig. 8). Then the variations of i will be represented by a straight line, Oi, and those of J by a curve, OJ. The ring B and the winding Σ should be so designed that the curve OJ, which rises at first more rapidly than the straight line Oi, cuts it at a point in the abscissa, of which Oh_1 represents exactly the voltage h_1 that the

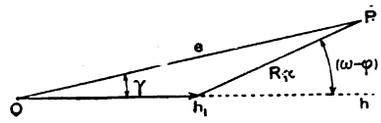

FIG. 9.

alternator should furnish. The precise adjustment will be arrived at by altering the self-induction bobbins λ in series with the windings Σ_1, Σ_2, and Σ_3.

Let $R=\sqrt{r^2+4\pi^2a^2l^2}$, and let us designate by a the strength of the current given by each of the armature circuits of the alternator at the voltage h, by ϕ the phase difference between the current and the voltage, and by e the E.M.F. which the rotation of the alternator ought to develop in the armature circuits to give the voltage h under these conditions of load.

It can easily be shown that the E.M.F. e can be determined as a function of the quantities h_1, a and ϕ, by the geometric construction represented in Fig. 9. Along a straight line Oh let us take a length Oh_1 proportional to the voltage h_1. From the point h_1 draw a straight line OP, whose length will bear the same proportion to the product Ra that Oh_1 does to the voltage h_1. Then the angle γ, between the lines OP and Oh represents the phase difference between the E.M.F. e and the voltage h_1.

We may consider the three E.M.F.s h_1, Ra, and e as developed by the rotation of three fields of strengths Oϕ, Oψ, and Oχ such that $\frac{O\phi}{h_1}=\frac{O\psi}{Ra}=\frac{O\chi}{e}$. These fields will rotate simultaneously with a speed a with respect to the armature of the alternator, which we assume to be bipolar (Fig. 10). The field Oχ will be generated by the field circuit, its rotation will depend only upon that of the alternator, while the phase of the movement of the field Oϕ, defined by the angle γ between Oχ and Oϕ will vary with the load on the alternator, and the directions Oχ and Oψ will enclose between them an angle $\beta=(\omega-\phi)$.

Let us now examine the case of the exciter, when each circuit of the armature of the alternator gives a voltage h, with a current a, the angle ϕ having a determined value. The winding Σ creates in the rings B and E a field Oϕ' (Fig. 11) which rotates with reference to it as the field Oϕ rotates with respect to the circuits of the armature of the alternator. But the ratio of fields Oϕ and Oϕ' is not constant. It varies with the voltage h according to a law which could be deduced from the curve OJ in Fig. 8. The winding S develops in the rings

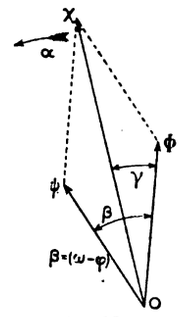

FIG. 10.

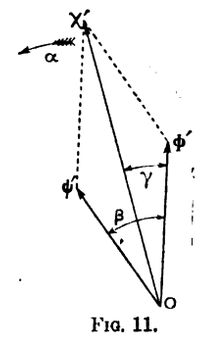

FIG. 11.

A and D a field Oψ', which is at each instant proportional to the product Ra, and the direction of which always makes an angle $\beta=(\omega-\phi)$ with the direction of the field Oϕ, owing to the displacement given to the rings A and B.

From Figs. 7 and 8 we see that,

$$\text{if } h<h_1 \text{ then } \frac{O\phi'}{O\phi}<\frac{O\psi'}{O\psi},$$

$$\text{if } h=h_1 \text{ then } \frac{O\phi'}{O\phi}=\frac{O\psi'}{O\psi},$$

$$\text{if } h>h_1 \text{ then } \frac{O\phi'}{O\phi}>\frac{O\psi'}{O\psi}.$$

When $h=h_1$, the Fig. 11 is similar to the Fig. 10, and as the direction Oϕ' is always the same as the direction Oϕ, the direction Oχ' corresponds with the direction Oχ.

The rotatory movement of the field Oχ' with respect to the rings A and B only depends upon the rotatory movement of the alternator. If the latter advances, the movement of the rings A and B is equally retarded. The direction Oχ' is thus fixed in space, and is invariable

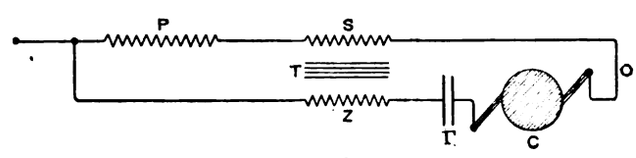

FIG. 12.

with reference to the brushes of the exciter as long as the voltage developed by the alternator is equal to h_1, and when this is the case we have

$$\frac{O\chi'}{e}=\frac{O\phi'}{h_1}=\frac{O\psi'}{Ra}.$$

But the exciter has been so proportioned that when the field Oψ' exists by itself, and has a direction at right angles to the line of contact of the brushes, its action produces a direct current capable of developing in each of the armature circuits of the alternator an E.M.F. equal to Ra; and the field Oχ' also having its direction at right angles to the line of contact of the brushes, will generate a current through the agency of the exciter capable of developing, by the agency of the field circuit of the alternator, in each armature circuit of the alternator an E.M.F. equal to e. But this is precisely the E.M.F. which should be produced if the alternator is to yield a voltage h_1 under the same conditions of load.

Now let us suppose that the voltage h is less than the voltage h_1. The E.M.F. between the brushes, and consequently the strength of the exciting current furnished by the exciter, will be proportional to

Digitized by Google

the sum of the projections of the lengths $O\phi'$ and $O\psi'$ upon the direction Ox', considered as invariable and at right angles to the line of contact of the brushes. The angle γ, between $O\phi'$ and $O\psi'$, will always be equal to the angle γ between $O\gamma$ and $O\phi$ of Fig. 10. Similarly, the angle β between $O\phi'$ and $O\psi'$ will always be equal to the angle β between $O\phi$ and $O\psi$.

But we shall have $$\frac{O\phi' \cos\gamma + O\psi \cos(\beta-\gamma)}{Ox} > \frac{O\phi'}{O\phi}.$$

The strength of the exciting current will be greater than would be necessary to maintain a voltage h at the terminals of the alternator. The latter, therefore, will increase until it has reached the value h_1.

Similarly, if $h > h_1$ we have

$$\frac{O\phi' \cos\gamma + O\psi \cos(\beta-\gamma)}{Ox} < \frac{O\phi'}{O\phi},$$

and the voltage will decrease until it has again become equal to h_1. Thus the alternator will always give a constant voltage, no matter what its load.

I think that I have shown in what has preceded that a rigorous solution of the problem of compounding *an alternator for constant voltage*, when its coefficients of induction are constant (a condition easy of fulfilment) can be obtained if the machine is constructed on the lines of the induction type of machine now in actual use.

We may try to apply the same method of compounding to alternators of the polar type, in which the fields are always strongly saturated; and though it will not be possible to arrive at the same rigorous solution, since the induction coefficients of these machine vary with their load, nevertheless, the variations of voltage occasioned by sudden changes of load may be sufficiently limited to allow of the output of the machines being determined by the heating of the conductors and not by the fall in voltage. Take the angle ω as equal to $\pi/2$, and proportion the ring B and the windings Σ and Z, so that the machine gives the desired voltage on open circuit. Then the ring A and the winding S will be arranged so that the machine will give the same voltage at full load. It will be useless in this case to saturate the magnetic circuits of the rings B and E. In Fig. 8 the curve OJ will be represented by a straight line, and the straight line Oi by a curve similar to curve OJ. These will always meet at a point, m, the abscissæ to which will measure the voltage that the alternator is to give.

The exciter described above as an example only presents the general type. It consists of two magnetic circuits, in which are developed separate revolving fields: the one by windings in series with the alternator armature, the other by windings in parallel with it. The two fields operate simultaneously upon a winding of a direct-current machine provided with a commutator.

This arrangement seems to be essential, and ought to be followed, whatever be the type of exciter or of transformer-rectifier which may be substituted for that described above. We will endeavour to prove this. Suppose we employ an exciter or a transformer-rectifier consisting of a single magnetic circuit. Then the E.M.F. e that the rotation of the alternator should develop in each of its armature circuits, when those circuits give a voltage h and a current of strength J is $e = h + rj + l\frac{dj}{dt}$, and the exciting current should be, at each instant, proportional to the E.M.F. e. This current could be produced by means of a commutator, between the rings of which an alternating E.M.F. equal to e was generated.

In order to simplify the problem, we may remark that the product rj being always small compared to the product $l\frac{dj}{dt}$, no great error will be committed by substituting for e, $e' = h + l\frac{dj}{dt}$.

This E.M.F. may be obtained in the following manner: Let P be one of the armature circuits of the alternator that we wish to excite (Fig. 12). In the figure it is shown in series with the primary circuit of a transformer, T.

The secondary, Z, of this transformer is placed in a shunt circuit between the neutral point O and the free end of the circuit P. In this circuit is the commutator C and a condenser Γ, the capacity of which is so adjusted that the apparent coefficient of self-induction of the secondary circuit Z is counterbalanced. In these circumstances, if we designate by m the coefficient of mutual induction of the two circuits of the transformer, the voltage at the terminals of the exciter will be equal to $h + m\frac{dj}{dt}$. Take m as equal to l. But we have supposed a condenser to be employed, and this is not practicable. If we take it away the circuit containing the rectifier will remain with a coefficient of self-induction L. Let us call i the strength of the current in the secondary circuit Z, then the voltage at the terminals of the rectifier will be equal to $h + \frac{mdj}{dt} + L\frac{di}{dt}$, and this expression differs entirely from that of the E.M.F. e'. If we wish to make the effective product of $L\frac{di}{dt}$ small as compared with the product $m\frac{dj}{dt}$ it will be necessary to give to the primary circuit of the transformer, which is in series with one of the armature circuits of the alternator, an enormous coefficient of self-induction. This will tend to greatly reduce the power of the alternator. In the arrangement we have adopted the secondary circuit Z of the transformer T is replaced by a winding of a direct-current machine provided with a collector, and its action annuls the effects of self-induction. Consequently it plays the part of the condenser Γ in the case examined above. It would be possible for us to do away with the transformer T, and to employ instead, in series with the alternator, the circuits of an exciter which would be subject to the action of an inducing circuit I excited by a direct current of constant strength furnished by an outside source (see Fig. 13), but we can see at once that this method of excitation would not permit of an exact compounding unless the cos ϕ of circuit were constant. But this condition is never realised, for the

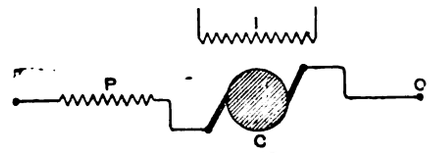

FIG. 13.

sudden variations of load occasioned by the starting of induction motors are always accompanied by a momentary, yet considerable, variation of cos ϕ.

CONCLUSION.

I believe that I have shown, in what has preceded, that there is the greatest advantage, both from the point of view of the best utilisation of material and of output, in adopting the induction type for both alternators and direct-current machines, and that it will be most profitable to excite them by means of currents, the strengths of which vary automatically with the loads on the machines, since the chief function of the field circuit will be not to create a useful field, but to give in every direction a magnetising force equal but of contrary sign to, that developed by the armature.

Further, I think I have proved that nothing is easier than to obtain such an automatic regulation of the exciting current, and the possibility of constructing machines according to the principles we have laid down has been demonstrated in practice.

At the Paris Exhibition, in the exhibit of the Société des Etablissements Postel-Vinay, there is shown a transformer-rectifier form of motor which may be regarded as a direct-current machine of the induction type. Further, in the exhibit of the Grammont firm there is a small alternator of 75kw. running at a speed of 800 revs. per min. which is also of the induction type. This machine is provided with an exciter identical with that described above. There is also a 1,000 H.P. alternator of the polar type, running at 94 revs. per min., and designed by M. Routin, in the same exhibit.* It has an exciter somewhat different to that I have described, but equivalent to it. There are also many machines similar to that exhibited by M. Postel-Vinay, which have been in service for several years, and their number is ever increasing.

The 75kw. alternator is certainly of small dimensions considering its output. It has been tested with the most satisfactory results, and by its means I have demonstrated—

1. That the excitation of machines of this description is automatic.
2. That a constant voltage can be obtained from the alternator under all conditions.
3. That the brushes of the exciter wear exceedingly well.
4. That machines of this type run perfectly in parallel with machines of other types.

As regards the large machine, it was first tested at the exhibition itself, and in these circumstances it was impossible to adjust its exciter exactly to the work it had to do. But it may be stated that the condition of its brushes is very satisfactory, and that the strength of the exciting current rises gradually with the load on the machine.

Elsewhere there are shown other methods of compounding alternators, devised by MM. Blondel and Boucherot and exhibited by MM. Sautter and Harlé and by the firm of Bréguet.

The Pollak-Virág Fast-Speed Telegraph.—According to the *Daily Chronicle* Messrs. Pollak and Virág have devised an important modification in their fast-speed telegraph. It will be remembered that in the original apparatus, the signals were received in the form of a wavy line, similar to that traced by the siphon recorder, on a slip of sensitised paper. According to our contemporary's report, the accuracy of which we, of course, do not vouch for, the inventors have devised a modification by means of which, instead of this record, messages can be actually printed on the photographic paper in ordinary round-hand Latin characters at the rate of 1,000 words per minute.

* This machine was described in *The Electrician* of Sept. 28, p. 845.—ED. *E.*

FUEL FOR GAS MOTORS.*

BY PROF. AIMÉ WITZ.

Among the advantages of gas-motors, is the fact that they can be fed with the most diverse of gaseous fuels, from rich combustibles like acetylene to gases as poor in calorific power as blast-furnace gas. In order to burn these different substances, the proportion of gas and air must be adjusted, a perfect mixture of the two obtained, and the degree of compression and mode of firing properly arranged. With a suitable carburetter, even liquid hydrocarbons of very different density and volatility—from petroleum ethers or gasolines to petroleum burning oils—can be used. To this great adaptabiilty of the motor is due the fact of its use in town and country, in the vicinity of a coal-gas works, or other gas-making plant, either as a stationary engine or for automobile purposes, and in sizes the capacity of which vary from a few kilogramme-metres to 1,000 H.P. The 1,000 H.P. motor is to-day a practical realisation of the dreams of inventors; for it is possible to connect, in series or otherwise, two cylinders similar to that of the motor shown in the Belgian section by the John Cockerill Company of Seraing. This machine is on the Delamare-Cockerill system of monocylindric type. Its cylinder measures 1·300 metres in diameter, and its stroke is 1·400 metres. Before a commission of expert engineers it has proved itself equal to producing from 560 H.P. to 670 H.P. when burning blast-furnace gas of 985 calories per cubic metre. It absorbs about 2,120 cubic metres per hour to give 670 H.P. According to the original statement of a famous inventor, smelting is really a secondary operation of a blast furnace, which may be regarded as a gigantic gas producer yielding 150 tons of pig-iron on the one hand, and 600,000 cubic metres of gas on the other. Reckoning half this gas for heating the blast and for other purposes, there remains a suplus of gas, from a blast furnace of 150 tons, sufficient to produce 3,500 H.P. in gas motors; 1,000 H.P., and sometimes not so much, is obtained with difficulty when the gases are used to raise steam.

The gas-motor has thus taken up its place as an adjunct to the blast furnace, and produces the most satisfactory results. Similar success awaits the engineers who shall use it with gas from coke furnaces. The producers of Dowson, Gardie, Lencauchez, Duetz, Pierson, Fichet and Heurtey, Bénier, and others, have paved the way for the future success of the gas-motor. In the earlier period of producer-gas making, it was necessary to use special coals, preferably anthracite, freed from powder, non-caking, with little ash, and yielding no fusible clinker—in short, a coal of such special character that only a high price could procure. But now it has gradually become possible to use ordinary anthracite coals of moderate price, so that the cost of the producer-gas has been greatly diminished, and the possibilities of the producers greatly increased. Electric power works, pumping stations, printing presses, looms, and spinning and other mills have taken their motive power from it with most satisfactory results. A 100 H.P. motor, working 3,000 hours per annum, fed with anthracite coal costing 25fr. per tonne, furnishes 1 horse-power hour for, at any rate, 4c.,† an advantage of about ½c. over a good steam engine in which coal at 20fr. is burnt. Its first cost is much less. The producer-gas varies from 1,200 calories to 1,600 calories per cubic metre. Gas producers are very suitable for coke; but the present high price of this fuel is not likely to encourage its use. A producer has recently been put down in Messrs. Brunner, Mond, & Co.'s chemical works at Northwich, in which small and bituminous coal can be consumed; and the recovery of the bye-products has proved most satisfactory. The complete apparatus is really a miniature gas works; but the cost of the kilowatt hour is placed at about 4c. (excluding interest and depreciation of plant), with Crossley motors of 25 H.P. power, a figure which justifies the expense of a complete plant. The Riché producer, using wood, gives a comparatively rich gas of 3,000 calories, which has been found to work well in Charon motors. It is an apparatus susceptible of many different uses in districts where wood for fuel can be found, and for this reason ought to extend the usefulness of the gas motor.

The water gas of Tessie du Motay has not been much used as a fuel for gas motors. The facts that the plant must have coke, and that it acts intermittently, are, no doubt, the explanation. The Dellwik producers, which give a gas of 2,000 calories, had a measure of success in Germany; while the tendency in America is to revert to the Lowe producer, as modified by Merrifield. Few experiments on the feeding of motors with water gas have been made; yet it has been shown that the engines behave as well with water gases as with mixtures of the latter and Siemens gas, whatever may be the proportion of nitrogen.

MM. Biedermann and Harvey have suggested the supply of carbon dioxide to gas producers. The gas (CO_2) would be reduced to carbon monoxide by contact with the incandescent coke. Should this idea become practicable, it would be possible to regenerate the waste gas of the motor, and so complete the cycle of changes involved in the use of producer or water gas as fuel. The high temperature of the escaping gas would doubtless be enough to maintain the reaction; and the heat of the waste gases would thus be recovered. Unfortunately, the nitrogen would accumulate in the recovered gas (due to the air supplied to the motor); and the whole volume of waste gas could not therefore be operated upon. The outline of this process, which has been mentioned in the third volume of "Traité des Moteurs à Gaz," suggests experiments which would be perhaps more interesting than practically useful, but which would nevertheless bear upon the theory of the question.

In regard to gases obtained by destructive distillation, their calorific power varies from 3,500 for gas from dried wood, to 5,350 for coal gas, and 7,500 for cannel gas. These are average figures; but I have found coal gas—the so-called house gas—to vary from 5,000 calories to 6,000 calories.* Ordinary house gas was that first supplied to motors, for which they were designed and made, from the machines of Philippe Lebon to those of Lenoir and Otto. With gases at 10c., 15c., 20c., and 25c. and motors of 4 H.P., 10 H.P., or 30 H.P., the cost per horse-power per hour can be found from the following table:—

Horse-power of motors.	Cost per horse-power per hour, with gas costing			
	10 centimes.	15 centimes.	20 centimes.	25 centimes.
4	11 centimes	14 centimes	17 centimes	20 centimes
10	9·7 „	12·7 „	15·7 „	18·7 „
30	8·5 „	11·5 „	14·5 „	17·5 „

These figures—which are not advanced as exact, since the factors are variable—show, at any rate, that up to 10 H.P. the gas motor has nothing to fear from any other motive power, even with gas at 20c.; while for 30 H.P. the price of the gas ought not to exceed 15c.

It is true that the gas motor on the town main possesses advantages which would obtain support for it, even if the cost per unit of energy were greater. These are briefly: No other plant, no furnace or fireman, no stock of fuel, put in or out of action at once, and no expense when not actually in use. Moreover, it can be placed practically anywhere; and, if properly constructed, it is so nearly noiseless as not to raise objection from neighbours. The last point has not always been realised; but this has more often been due to the fixing of the motor and its accessories than to the machine itself.

In towns, the applications of gas-motors have not developed to the extent which might reasonably have been anticipated from the improvements of the past 10 years. Now that 1 H.P. per hour can be obtained by the consumption of 500 litres of gas of 5,350 calories per cubic metre at 0°C. and 760mm, the use of such motors ought to be profitable and economical in many industries. It is astonishing to find that the Paris Gas Co. sold only 10,013,000 cubic metres of gas in 1899 for use in motors in Paris and the suburbs. This is scarcely $\frac{1}{33}$rd of the total make—say about 3 per cent. In Germany, certain works supply 17 per cent. of their gas for motors, although the price of gas is not less than here nor the motors superior. It may therefore be hoped that the progress in this direction which has been evident in Paris in the present year owing to the exhibition, will continue, and that there will be an increasing demand for gas for use in motors. The enrichment of house gas by carburetting has been tried, but it seems as though this is of no advantage to the consumer who uses the gas as a motive power. Acetylene gas, of which premature hopes were entertained, has not given any very encouraging results, in spite of the able work of MM. Ravel, Cuinat, Franck, and many others. I am not aware of a single application in this direction. All that has been done has been to show that the gas motor can work with such a rich gas; but it still remains to make it practical. Experimental results confirming the preceding statement are in favour of the gas-motor which, as has been mentioned, can be fed with blast-furnace gas of 900 calories, or with acetylene of 14,000 calories per cubic metre. M. Lencauchez has also shown (in the analysis of a number of more or less official reports) that the thermal yield of motors varies appreciably with the richness of the gaseous fuel. The trials I have made at Seraing and Differdange confirm this statement, inasmuch as the horse power per hour could be obtained with 3 metres of gas of 980 calories, equivalent to 549 litres of gas of 5,350 calories. This number corresponds to a yield in actual work of 21·7 per cent., and in indicated work of 25 5 per cent. But I have never obtained more than 21·1 per cent. and 26 per cent.

* Paper read before the International Gas Congress at Paris.

† I reckon 5 per cent. for interest, 3 per cent. for depreciation of buildings, and 6 per cent. for that of machines and materials.

* This relates to the calorific power at constant volume (steam condensed), as determined by means of my eudiometric bomb. I obtain complete combustion, which is not always the case with poor gases in calorimeters which burn the gas at constant pressure.

THE USE OF CONDENSERS.*

BY P. BOUCHEROT.

All the applications of condensers to industrial alternating currents may be considered as the consequence of electric resonance, and therefore of the oscillating discharge or charge. If C is the capacity of the condenser, L the coefficient of self-induction of the discharge circuit, and R the resistance of the circuit, the discharge is continuous for $R^2 > 4L/C$, that is to say that the discharge current which has at the moment of the closing of the circuit a certain value, diminishes to zero without passing through negative values. On the other hand, the discharge is oscillatory for $R^2 < 4L/C$, where the discharge current does not become zero until having passed through a series of positive and negative values. The periodic time of such a discharge is constant, that is to say, the time which elapses between two zero values of the current is the same at the beginning or at the end of the discharge. It does not depend in consequence on the actual value of the electric charge and is given by the expression

$$T = \frac{2\pi}{\sqrt{\frac{1}{LC} - \frac{R^2}{4L^2}}}.$$

In the particular and exclusively theoretical case when the resistance of the circuit is zero, the periodic time becomes $T = 2\pi\sqrt{LC}$, a formula which, singularly, follows that of the periodic time of oscillation of a pendulum in a vacuum. In this case the energy stored primarily in the condenser cannot be dissipated as there is no resistance, and in consequence no RI^2, so that the discharge lasts indefinitely, that is to say, there exists for an indefinite time an alternating current in the circuit with the periodic time $T = 2\pi\sqrt{LC}$. It is evidently quite a theoretical case as one supposes that $R = 0$, which is an impossibility. But if it is not possible to make $R = 0$ it is easy to compensate constantly the loss of energy RI^2 by the introduction into the circuit of a source of current very weak compared with the energy acting in the circuit. If it is desired to make the amplitudes of the oscillations of the current independent of the time, this added E.M.F. must be of the same frequency as the alternating current due to the circuit formed by the condenser and the self-induction or the resonating circuit, *i.e.*, the periodic time of the E.M.F. must be $T = 2\pi\sqrt{LC}$. If it is, there will be resonance by analogy with the acoustical phenomena, but the circuit will only resonate for a current with a frequency corresponding to $T = 2\pi\sqrt{LC}$. For this current only, may Ohm's law be applied when taking account of the E.M.F.s of induction or capacity. Let me remark that this E.M.F. may be introduced into the circuit in any manner, and all kinds of applications are possible. I will examine the most important, and, to avoid repetition, I will say at the outset that a condenser and a self-induction are in all cases adjusted until the relation between the two is $4\pi^2LC/T^2 = 1$.

I. *Condenser in Series.*—Let us open this resonating circuit, and connect in it a source of alternating current—for instance, an alternator whose frequency is exactly $T = 2\pi\sqrt{LC}$. Under these conditions the current which will flow through the circuit will be exactly what would flow if there were only resistance—*i.e.*, if the self-induction and capacity were absent. This is what is implied when it is said that the capacity neutralises the effects of self-induction if it is properly adjusted to it. A curious detail is that if we have, for instance, 100 volts at the terminals of our circuit—*i.e.*, 100 volts produced by the alternator—we could quite well have 1,000 volts or 10,000 volts at the extremities of the induction coil or between the plates of the condenser, in consequence of the large quantity of energy which can be stored up in each of these apparatus in comparison with that furnished by the alternator during one period. The condenser can thus be employed to annul the effects of self-induction in a circuit. If, for instance, it is desired to pass through a circuit a larger current than that which the self-induction would permit with the pressure available, it is only necessary to include a suitable condenser. This property has been applied in certain simple alternate-current motors for the excitation of the field magnets, and may be applied usefully whenever one wishes to produce an alternating magnetic field without the apparent power furnished by the apparatus being much greater than the actual power expended by the Joule effect, and without being obliged to have an E.M.F. greater than that corresponding to the ohmic drop in the excitation of the circuit.

II. *Condenser in Shunt.*—Let us close our resonating circuit as it was at first, and let us connect between the two plates of the condenser a source of current. This source must have the same frequency as above. Under these conditions the current which the alternator will furnish to the condenser and that which it will supply to the self-induction and resistance may each be much greater than their sum—*i.e.*, greater than the total current furnished by the alternator in the two circuits. The latter will be strictly equal to the current which, at the pressure of the alternator, would give a power equal to the Joule effect, while each of the shunt currents will be greater in consequence of the superposition of the current of resonance. This property permits of the reduction, by means of condensers, of the magnetising currents absorbed by all the apparatus which do not produce their own magnetic fields, such as transformers, reaction coils, asynchronous motors, &c.

In the application to transformers and asynchronous motors, condensers may be shunted either to the primary or the secondary. If resonance is produced in one or other of these circuits the source of energy need not supply exciting currents. One can even produce resonance in a tertiary circuit which, in the asynchronous motor, may be wound either on the stator or rotor. These different combinations have been proposed and tried on transformers and both single-phase and polyphase asynchronous motors.

III. *Splitting up an Alternating Current.*—We now come to other applications of condensers in which the effects produced follow in a slightly less evident manner from resonance, because other currents of equal importance are superposed upon the resonance current properly so-called and complicate the phenomenon. At the head of these applications must be placed the splitting up of an alternating current into two currents differing 90deg. in phase. By connecting to a source of alternating current two shunted circuits, one containing a resistance ρ and a self-induction whose reactance is ρ, the other containing a resistance ρ and a condenser whose reactance is $-\rho$, the two shunts are the seat of alternating currents differing 90deg. in phase. So far, this arrangement has no particular interest, but if one replaces each of the resistances by one field circuit of a two-phase asynchronous motor, and at the same time modifies the reactance of the circuit so as to take account of the reactance of the motor circuits, an asynchronous motor can be driven with a simple alternating current. This application of condensers would be one of the most important; but even if an industrial condenser was to be had it would still meet with serious difficulties in its realisation, from the fact that the capacity ought to vary every instant with the load.

IV. *Constant Current Regulation.*—Condensers can also be used in combination with induction coils to obtain circuits with currents by means of constant E.M.F., and inversely. They permit, therefore, of a series distribution from any number of circuits branched on to a source of constant pressure, as, for instance, on an ordinary alternating-current supply circuit. For this it is only necessary to connect on to the constant-pressure mains a constant-current circuit and to shunt to it a condenser in series with a self-induction coil. The condenser and self-induction must be adjusted to constitute a resonator. Naturally each resonator must be connected to the constant-pressure circuit through the intermediary of a transformer, and this transformer having a self induction, the self-induction of the resonator may be eliminated and the system reduced to a transformer and a condenser. The same result may again be obtained more advantageously by the employment of a double resonator, constituted as follows: Two self-induction coils and two adjusted condensers are grouped to form a quadilateral ACBD in which the smaller apparatus are on opposite sides. Then by connecting the two opposite angles AB of the quadilateral to a source of constant E.M.F. one receives in a circuit placed between the two other points D and C a current which is constant whatever the impedance of the circuit. I will not dwell longer on these applications, but will only point out that the employment of two resonators, or more accurately of two condensers and a self-induction coil (or two self-induction coils and a condenser) permits the connection of two alternators in series, and also the realisation of an apparatus equivalent to an ordinary transformer transforming a current of constant pressure to another current of constant pressure.

V. *Excitation of Alternators.*—Just as condensers can furnish current for transformers and asynchronous motors they can also be used to excite alternators, and different systems of alternate-current generators could be devised in virtue of the following mechanism, which is, besides, the whole secret of resonance. In general, in an induction machine, an E.M.F. is the differential coefficient of a flux with respect to time, but with its sign changed. Its phase is therefore a quarter of a period behind the flux. If this E.M.F. is connected to condensers the current advances a quarter of a period on the E.M.F., and is therefore in phase with the flux, and in consequence can produce the flux. Condensers placed as a shunt to the armatures of an ordinary alternator can, by suitable arrangements in the alternator and by modifying its proportions, produce the field of this alternator.

We will cite two more systems of generators which can be excited by condensers. In the first there is no field magnet. A fixed armature and a moving armature with the same number of poles, the same number of phases, and the same number of turns, are both the seat of induced currents with the same frequency and the same pressure, in consequence of the rotation of the magnetic field, which moves in the two at a speed half that of the moving armature, and is produced by electromotive forces obtained with

the aid of condensers. In the second there are only two circuits, both fixed, and each with a coefficient of self-induction varying periodically and of the form $\lambda(1 \pm \sin 2\omega t)$, and between them a coefficient of mutual induction $-\lambda \cos 2\omega t$. But what is particularly interesting with all these generators, excited by condensers, is that by this means one can realise in these machines the same methods of excitation as with continuous current dynamos. If the condensers are placed in shunt the characteristic of the machine is the same as with a continuous-current shunt dynamo. The E.M.F. is a maximum at no load and diminishes when the machine is loaded, and the curve bends round if a certain load is exceeded. If the condensers are placed in series, the characteristic is that of a series continuous current machine, *i.e.*, the E.M.F. of the machine is zero on open circuit, but increases when the resistance of the external circuit is increased. Finally, on combining the two preceding methods of excitation one can realise a machine whose characteristic is that of a compound continuous current dynamo. Just as in these machines, the connection corresponding to a long shunt and a short shunt compound dynamo can be made, and one can also over-compound the machines.

This concludes the enumeration of the most important applications of the condenser and shows the importance this apparatus might attain in the great alternating current industry if two main reasons had not opposed its development up to the present. These two reasons are first, its price, which so far has been too high for the majority of applications, and second, the phenomena of resonance themselves which, in certain cases instead of being useful became harmful and destroy the dielectric of the condenser. Various materials have been tried for the dielectric. Among the solid bodies, glass (Jablochkoff, 1880) and mica, which seem only to have given medium results, paraffined paper, ebonite, oiled paper, paper coated with wax, and, more recently, stearate of lead and pure paraffin without support. Some liquid dielectrics have also been tried. Of all these dielectrics it seems to me that paraffined paper has been tried the most. I have not found detailed information with regard to the other substances. Paraffin has the disadvantage that its melting point is low and that it is easily inflammable, and it is to be wished that a dielectric might be found with the same insulating qualities and the same specific inductive capacity as paraffin, but less fusible and less inflammable. It seems that at present the price of condensers applied under normal conditions for ordinary frequencies of 40 ∿ to 50 ∿ per second and for pressures between 600 volts and 3,000 volts, lies between 80f. and 150f. per kilowatt, a 1kw. condenser being considered as that in which $\frac{2\pi}{T} E^2 \omega C = 1{,}000$. The price is practically proportional to the power, one condenser for 100kw. being virtually 100 condensers for 1kw. As a result, the price, which is small when compared with that of small machines costing 200f. to 500f. per kilowatt, is very large compared with the price of large machines which cost from 70f. to 80f. per kilowatt, so that up to the present the application of condensers has been confined to small powers.

But the second reason against the use of condensers up to the present in large installations is, perhaps, more important. It is the accidental production of very high pressures resulting through resonance effects, from sharp variations in the load, short circuits, failures in insulation, or in one word, from the numerous incidents which must occur in the work of a central station. It is certain that the phenomena of large increases of pressure which have been shown many times by the puncture of cables, for instance, do not occur everywhere, but only in large high-pressure installations in which there is a capacity shunted to the line. It seems therefore that even if their price does not oppose them, the adoption of condensers in large installations is dangerous both for the condensers themselves and for the whole installation. But I think that there must be a capacity at which the harmful effects pass through a maximum, and beyond which the increase in capacity has rather a beneficial effect, moderating the sharp rises in pressure. I should not be surprised if certain installations were already in the neighbourhood of this maximum, thanks to the capacity of their cables, and that in these installations the addition of condensers of large power, when their price is more reasonable, will be an advantage, not only by an improvement in the power factor but also with regard to the conditions of security.

Now it only remains to say a few words about other apparatus which can act to a certain extent as condensers. Over-excited synchronous motors employed for this object do not seem to me to be an advantageous solution, because their cost is almost as high as that of condensers, and because of the loss of energy which they occasion, the necessity of starting them, and the maintenance and attendance on them and their exciters. I think it is preferable in this case to add generating units at the central station. On the other hand, I believe that synchronous motors can be used advantageously when they actually act as motors at the same time. Electrolytic condensers (capacity of polarisation) constituted by electrodes plunged into a solution of carbonate of soda absorb much energy. Their resistance is practically equal to their reactance for a frequency of 40 ∽ per second. It is, therefore, only in quite special circumstances, such as the starting of single-phase motors, that they can be applied. One must not think of leaving them in a circuit. In short, I do not think that this apparatus can be substituted for the condenser properly so-called, and that efforts should be made to make the condenser a less costly and really industrial apparatus.

ON THE PHOSPHORESCENT GLOW IN GASES.*

BY JOHN B. B. BURKE, M.A.

When an electrodeless or ring discharge is sent through some highly rarefied gases, a phosphorescent glow is produced, which usually lasts for several seconds and in some instances as long as one or two minutes. A long series of experiments has been carried out to investigate the properties and nature of the glow, and some of the results already obtained show that the phosphorescence is due to molecules, which do not carry a change of electricity, but which nevertheless produce conductivity as they move through a gas, and at the same time are rapidly broken up or destroyed in the ionised gas.

The method of producing the electrodeless discharge was one of the two originally employed by Prof. J. J. Thomson. The inner coatings of two large Leyden jars were connected to the terminals of a powerful Wimshurst machine, and the outer coatings were connected by a coil of a few turns of wire. Whenever a spark passed between the terminals of the Wimshurst, rapid alternating currents were set up in the coil, which at pressures below 1 cm. gave rise by induction to the passage of a discharge having the appearance of a ring through the gas in a bulb placed inside the coil. At lower pressures, within certain limits, which in air lie between 0·7 mm. and 0·02 mm., the gas becomes phosphorescent, and it was this phosphorescence or afterglow that formed the subject of investigation.

The glow is easily produced in ordinary commercial oxygen, but in electrolytic oxygen it is difficult to obtain, whilst in air it is most persistent. Hydrogen does not give a glow, whether pure or with slight traces of oxygen, but oxygen appears to be a necessary element in the production of the phosphorescence, yet it is not due to oxygen alone. Thus Newall had found that the colour of the glow in oxygen is different according to the nature of foreign bodies present; thus in oxygen with carbon the glow was white, in oxygen and nitrogen yellow, and in oxygen and sulphur blue. The colour of the glow in cyanogen is white, the same as in mixtures of oxygen and carbon, and in air yellow, as in mixtures of oxygen and nitrogen.

When the ring discharge is sent through a bulb at the end of a long tube 2m. in length and 2cm. in diameter the afterglow, which starts at the bulb, travels down the tube with a velocity of about 2m. per sec., but in narrower tubes the velocity is much reduced. That the glow is not due to electrostatic effects which creep along the glass tube, is proved by the fact that when a brass tube, well earthed, is interposed between the glass tube and the bulb, the glow travels down as before, showing that the phosphorescence is a volume effect in the gas. The glow can be made to diffuse through narrow brass tubing 1mm. in diameter, but in this case the rate of diffusion is very small.

Two large bulbs were connected by a brass tube of 1mm. diameter with a tap, and well earthed, and when the ring discharge was sent through one the glow diffused slowly into the other bulb when the tap was open, but not when it was closed, showing that an actual diffusion had taken place, in the first instance, from one bulb into the other, and that the glow in the second bulb was not due to any induced effects due to the discharge in the first bulb.

The diffusion of the glow through so narrow a metal tube put to earth shows that the glow cannot consist of electrified particles. The glow in the second bulb lasts three or four times as long as that in the first, through which the discharge has passed. The only difference between the gas in the two bulbs is that that in the first has been ionised, whilst that in the second has no trace whatsoever communicated to it by the spark, since the ions are stopped, and cannot diffuse through the narrow tube. Thus the brass tube and tap act as a veritable Maxwell's demon, which lets through the phosphorescent molecules but catches the ions.

The view that the glow is rapidly destroyed by ionised gas is confirmed by the fact that when a discharge from a small induction coil is sent between two electrodes in a side tube projecting from the second bulb the glow then is rapidly destroyed.

An E.M.F. will not stop the phosphorescent particles; nevertheless the glow conducts, as can be shown when the glow reaches a pair of electrodes placed close together in one of the long glass tubes already described. This conductivity may be due to the breaking of the phosphorescent molecules by the ions already produced by the spark.

SOME NEW ELECTRIC HEATING APPARATUS.

Messrs. O. Berend & Co. have sent us the following particulars of some new patterns of electric heating apparatus made by the "Prometheus" Co. of Bockenheim, for which company Messrs. Berend are sole agents. The electrical energy is converted to heat through resistances formed of thin films of precious metals, such as gold, platinum, &c., deposited on an insulating base of mica, enamel, or other suitable material. Resistances up to 25,000 ohms, it is said, can thereby easily be obtained. A mica strip $5\frac{1}{8}$in. × $1\frac{3}{16}$in. × 0·004in. thick, coated under the "Prometheus" patents with a film of metal is employed, with a resistance of about 120 ohms. It is estimated that a room of about 3,500 cubic ft. capacity may require some 2,000 to 2,500 large calories per hour to warm it, and, allowing a margin for wasted heat, 30 of these resistances would therefore be required at 110 volts. The weight of the mica strip is practically nil, and the terminals or connections can be kept very light; the combination therefore absorbs but little heat and practically the whole of the energy is at once available. In practice, to ensure durability, it is desirable that the temperature of the strips should not exceed 450°C.; this corresponds to 70 watts or 75 watts per strip. At 90 watts to 100 watts the strips show dull red in the dark and oxidation would then occur.

The stoves designed by the "Prometheus Co." for these strips are circular, and, of course, the number of strips employed depends on the size of the stove. The strips are mounted in two rows on a frame fitting into a circular case, the outer row, therefore, radiates heat directly, and a continual current of air passes up and is heated between the two rows. As each strip is independent and connected to the circuit in parallel, any one can be replaced or removed without altering any connections. The smallest pattern of stove contains 12 strips, weighs 5lb., and takes six to eight amperes at 110 volts; the next size contains 24 strips, weighs 10lb., and takes from two to 16 amperes at 110 volts; and the large size contains 48 strips and weighs 15lb. The two latter are fitted with a step switch enabling the stoves to be used from quarter to full power in four steps. Messrs. Berend estimate that in ordinary conditions the small size radiators will be sufficient for heating rooms of from 700 to 900 cubic feet, the medium size for rooms of 1,400 to 1,800 cubic feet, the large size for rooms of 2,500 to 2,800 cubic feet capacity.

The bases of the stoves are said to remain quite cool, and the apparatus may therefore be used anywhere. To give the stove a cheerful appearance when working, a ruby lamp is arranged behind the mica strips and shines through and between them, shedding a cheerful light throughout the room.

AUSTRALIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

Electric Power for Gold Dredging.—The first electrically-driven plant for the recovery of alluvial gold by dredging with centrifugal pumps has recently been introduced in Victoria by the Hon. J. A. Wallace, M.L.C., at Sandy Creek, near Yackandandah. The generating plant consists of a 500kw. polyphase steam-driven Stanley induction alternator situated some half mile from the barges. The power is transmitted on temporary overhead construction. Each dredging barge contains a 250 H.P. motor driving a Wallace-Hedley gravel pump by means of a 24in. Worral friction clutch and rope gearing; also a similar 150 H.P. set for the hydraulic pumps. The main gravel pumps work with 20ft. suction and 40ft. head. The small size and consequent mobility of the electrically operated barges, as compared with those containing a complete steam plant, give them a very important advantage in such work, and this method of driving will probably be largely adopted in the near future in the extensive dredging fields of Victoria and New Zealand.

Electric Pumping of Sewage.—The Sydney (N.S.W.) authorities are moving rapidly in electrical matters. The latest introduction consists of an extensive system of electrical distribution of power for pumping sewage. Hitherto the municipal authorities situated on the shores of Port Jackson have poured their sewage directly into the sea, converting the water into a condition belying the title of "the most beautiful harbour in the world." In future the sewage is to be raised by 21 electrically-operated pumping stations into a high-level system, whence it runs by gravity well out into the ocean at Bondi. The power is supplied to these stations at 500 volts from the Government generating station at Ultimo by means of cables carried partly overhead and partly underground. The arrangement will prove very useful in raising the load factor on the station as well as in solving a difficult problem in sewage disposal. Power from the same source is also to be supplied for operating the Pyrmont and Glebe Id. swing bridges.

Proposed Legislation.—In view of the approach of Federation, the Electrical Association of New South Wales is pushing forward some legislative questions of great importance to the electrical industry. The free trade colony is dreading that the non-technical federal legislators in drafting the new tariff may consider electricity as a luxury and retain the 25 per cent. duty at present in vogue in most of the colonies. In view of the importance of the industry and its dependence on outside manufacture, 10 per cent. is suggested as a limit in the federal tariff. Legislation is also called for in order to give statutory powers to undertakers of electrical supply. At present no such powers exist except in so far as created by special acts of Parliament in individual cases. The expense involved in the passing of such an act has usually proved quite prohibitive even when there is a universal demand for the light. Recent legislation has helped to remove this difficulty as far as Victoria is concerned.

Electric Traction.—Electric traction is making rapid progress in Australia. In Sydney the Government are replacing section after section of the old steam trams by the trolley wire. The opening of the latest section of some two miles to Cook's River was celebrated by the Electrical Association of New South Wales in a characteristically colonial way by a "trolley car party." The authorities do not contemplate extending the capacity of the power house at Rushcutter's Bay, the necessary plant for the whole network being installed in the central generating station at Ultimo. Private enterprise, too, is not idle. A line has been opened from Rockdale to Lady Robinson's Beach, New South Wales. The plant for working this line is a most up to date character, consisting of direct coupled Willans-Siemens generating sets running at 400 revs., Babcock and Wilcox boilers fed by electrically driven pumps and working up to 300lb. per square inch, and Chloride accumulators. The system has proved very successful. In Brisbane the tramway company are seeking powers for large extensions, and in Melbourne in spite of their ideal system of cable cars, the suburban authorities are proposing a trolley line connecting the suburbs with each other directly, the cable system being entirely a radial one. In Adelaide matters are delayed pending a decision as to the authority by whom the work is to be undertaken. Messrs. Callenders and the Westinghouse Companies have a bill before Parliament seeking powers to convert some 50 miles of the present horse lines. In the meanwhile the suburban authorities have formed a trust with the same object, and if they prove successful in getting the City Corporation to join them and in raising the necessary capital £800,000), the Government have expressed their intention of giving them the necessary powers. In this case they will probably get the firms already mentioned to undertake the equipment on a short lease. If they are not successful, the Government intend to undertake the conversion themselves, as has been done in Sydney. The main difficulty hitherto in the completion of the municipal scheme is a pledge which the City Corporation was drawn into some months back to support a fourth proposal made by an outside company promoter. This gentleman has now failed to fulfil his financial guarantees, and, the Corporation being thus freed, no great difficulty is anticipated in carrying out the municipal proposals with the financial support of the constructing companies. The improvement in the tramway service is certainly very necessary, the average speed of the present horse trams being only some 5 miles to 6 miles per hour.

Proposed Power Station for Kalgoorlie (W.A.).—Electrical development progresses very slowly in the Australian mining centres. At Kalgoorlie (W.A.) the mines hitherto have only attempted to employ electric power for lighting by means of isolated steam plants of 5kw. to 50kw. capacity. In addition, the town is supplied from a small municipal plant of 250kw.

Digitized by Google

A syndicate has recently been formed proposing to erect a central station of 5,000 H.P. capacity, from which energy for lighting and power for mining and milling will be distributed to the surrounding mines.

Barron Falls Water-Power Scheme.—The question of the electrical utilisation of the Barron Falls (Q.) has been unfortunately postponed by the interference of a Conservative Labour Ministry who recently captured the Queensland Treasury Benches for a few weeks on a catch vote. The former Government had drawn up an agreement with the Chilligoe Railway and Mines Co. for the utilisation of 75,000 H.P. for 50 years for a total rental of £42,000. The power is to be employed by the Company for lighting, traction, and power on the Chilligoe Mines, and it is to be hoped that the proposals, which are favourable to both sides, will shortly be taken up again by a more liberal government.

CORRESPONDENCE.

COHERERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: There seems to be a tendency to regard the metallic cohesion which occurs under the influence of an imperceptible spark as a *theory*, whereas it is a fact. I observed the fact 10 or 11 years ago, and published it in the *Journal* Inst.E.E. for 1890. Prof. Hughes had observed it before, so had S. A. Varley before that. I spoke of it as an apparent extension or reaching of the force of cohesion across a molecular gap under the influence of, as it were, an electrical *flux*.

Whatever it be due to, there can be no question that metals such as brass and iron, when in light contact, do cohere under the influence of electric waves, for they can be *felt* to have stuck together. So also filings mat themselves visibly together on a glass plate, and can even be got to hang as a string, one suspended from another.

Prof. Chunder Bose's observations and further investigations are interesting enough, and I am glad to call attention to them, but no amount of investigation or "correspondence" can disturb the above physical fact. There may be, and apparently are, anti-coherers which act in an opposite direction, but certainly there are coherers.—Yours, &c.,

The University, Birmingham, Oct. 6. OLIVER J. LODGE.

An Electrical Theory of Gravitation.—The *Electrical World* of New York of September 29th contains an article by Prof. Reginald A. Fessenden on "An Explanation of Gravitation." In this article Prof. Fessenden gives a sketch of his electrical theory of gravitation—a theory which is, at all events, an ingenious dovetailing of various ancient and modern hypotheses connected with gravitation and electricity. The author starts by commenting on J. J. Thomson's theorem that the addition of a charge to a body increases its inertia, owing to the electromagnetic reactions induced by the motion of the body. Then, taking the modern corpuscular theory of the atom, he affirms that the enormous charges carried by the intra-atomic corpuscles suffice to explain the very considerable inertia possessed by a piece of ordinary matter. "Inertia," he concludes, "is an electromagnetic induction effect, due to the corpuscular charge." Next, the author mentions the result of Quincke's experiments on the expansion of dielectrics submitted to electrostatic stress, and states that, in general, on introducing a dielectric into an electrostatic field the density of the ether in the region as well as the density of the matter changes. This change of density of the ether must be very great in the strong electrostatic field near an atomic corpuscle. Thus, using Newton's suggestion as to the cause of gravitation, Prof. Fessenden concludes, "gravitation is a secondary effect, the electrostatic intensity due to the corpuscular charge causing a change of density in the ether surrounding it, this latter giving the gravitational attraction." Throughout the article the author seems to assume that the corpuscles of an atom are all charged similarly.

MUNICIPAL, FOREIGN & GENERAL NOTES.

Asylum Lighting.—The Fife Lunacy Board have authorised their consulting engineer (Prof. F. G. Baily) to obtain estimates from four or five electric lighting firms for the electric lighting of the asylum.

Ayr.—The accounts of the Electricity Department for the year ended May 31 have been issued. The total receipts (including public and private lighting) amounted to £5,244. 15s. 2d., and the expenditure to £3,479. 10s. 11d., leaving a balance of £1,765. 4s. 3d. Interest (£1,539. 12s. 8d.) and sinking fund (£930. 8s. 3d.) came to £2,461. 0s. 11d., leaving a net deficiency of £695. 16s. 8d. 499,355 units of currents were generated; 257,600 were supplied for public lighting and 168,039 to private consumers, and 12,000 units were used on the works. There are 82 arc and 117 incandescent electric lamps employed for public lighting, and the total maximum supply demanded was 256kw. The loans sanctioned amount to £50,000, and the amount borrowed to £42,977. 7s. 8d.

A report from Mr. W. A. Chamen, city electrical engineer of Glasgow, was submitted to the Ayr Council on Monday. Mr. Chamen strongly urges the Corporation to change their present system—high-tension alternating current—to low-tension continuous current. This change was recommended by the Works committee, and the Council unanimously approved the recommendation. Tenders for new plant were accepted.

Birmingham.—The work of converting the Bournbrook electric tramway route to the overhead trolley system has been commenced. The work is being carried out under the supervision of committees of the Council.

Bradford.—The accounts of the Electricity department for the half-year ended June 30 were presented at the meeting of the Corporation on Tuesday. The chairman of the Electricity committee (Mr. T. Shaw) said that the total income was £17,723. 9s. 5d., compared with £13,256. 12s. 11½d. in the corresponding period last year. The total expenditure, including interest and sinking fund, was £16,751. 1s. 3½d., against £11,523. 10s. 4d. The net profit for the half-year, therefore, was £972. 8s. 1½d., against £1,733. 2s. 7½d. The number of consumers was 1,175, against 965. The total number of units consumed was 1,419,409, against 996,807, an increase of 45 per cent., irrespective of current supplied for public lamps. The total profit since the opening of the works in Sept., 1899, after paying interest and sinking fund, amounted to £26,986. 0s. 6½d., and the total amount written off for depreciation had been £14,372. 17s., leaving £12,613. 3s. 6½d. to be appropriated as the Council might direct. The accounts were adopted without discussion.

At the same sitting Mr. E. R. Hartley moved—

That, in the opinion of this Council, it is desirable that the Corporation should have control of the supply of coal required by the Corporation for use in their various undertakings, and that it be an instruction to the town clerk to insert in the bill to be promoted in the next session of Parliament a clause empowering the Corporation to become the owners of and to work a colliery or collieries, with power to borrow the necessary moneys required.

Mr. Hartley contended that, in the interests of the city, some such step was necessary. He had taken the increase in the price of coal at 5s. per ton, although others had put it at 7s. 6d., and on that basis he estimated that the extra cost of coal required by the Corporation this year would be equal to 10d in the £ on the rates. The consumption of coal in the whole of the city was 1½ million tons per year, which meant that the city would pay for its coal an increase in price of £375,000. The total rates of the city were £400,000 per year, so that the increase in the price of coal was equal to doubling the rates. He proposed that the Corporation should have the means to provide for its own coal supply, and not be dependent on a monopoly. Ald. Wood, who seconded, said the Manchester Corporation had taken the matter up, and he thought no harm could be done by trying to secure a mine. Mr. Land pointed out that the Corporation had to have contracts with something like 20 collieries in order to make certain of a proper supply of coal. Eventually the resolution was carried by a large majority.

At a special meeting of the Tramways committee on Wednesday it was decided to recommend the City Council to enter into an agreement with the Shipley Council for working the proposed tramways to Shipley. It was also decided to apply for powers to construct several additional lines connecting with the existing tramways.

Brighton.—In the bill which the Corporation have decided to promote next session power is to be sought to enable the Corporation to purchase and hire out to consumers or wiring contractors electric motors, cooking, heating and ventilating apparatus. Feeder No. 11 is to be extended to the south side of Grand Junction-parade at an estimated cost of £2,500.

Bristol.—The Electrical committee have decided to make an alteration in the charge for electricity for motive power and heating.

Digitized by Google

In future the minimum charge of £1. 5s. per quarter per kilowatt supplied will be abolished, except in cases where the consumer has an alternative source of supply, and the charge will be 1½d. per unit only, irrespective of quantity used, subject to discounts, and with no charge for motor hire. Motive power customers will be required to enter into a special agreement, providing, amongst other things, that if the electricity supplied under the agreement is used for lighting, either directly or indirectly, the Corporation shall annul the agreement without notice to the consumer, and thereupon the latter shall pay for the electricity supplied to him according to the then existing rate for electricity for lighting. Extensions of the lighting mains have been authorised.

The Dock committee reported to the Council on Tuesday that they had been requested by the Petroleum Company to furnish a supply of electric current, and, being in a position to give a supply from their new works at Avonmouth, recommended they be empowered to make the necessary arrangements. Ald. Pearson, chairman of the Electrical committee, questioned the advisability of two committees supplying electricity, possibly in competition with each other. Some time ago the Electrical committee were asked if they were prepared to supply electric current at Avonmouth, and declined, not realising the large demand that was likely to arise. Had they been informed the demand would have been so large, it would have been worth while considering whether the supply could not be economically given from the central station. It was, he feared, too late for his committee to intervene now. The report was agreed to, and the company will be supplied with current by the Dock committee.

Burnley.—The Corporation intend to reconstruct the tramways in this district, and notice to this effect has been given to the various authorities into whose districts the system extends.

Bury.—Messrs. Lacey, Clirehugh and Sillar have been appointed consulting electric tramway engineers to the Council.

Bury St. Edmunds.—Sanction to a loan of £800 for public electric lighting has been obtained, "but no part of the loan may be applied in providing incandescent lamps."

Cable Communication with China.—The cable which was laid been Chefoo and Tientsin for the German Government was opened for the transmission of messages on Thursday last, and Kiao-Chau thus becomes connected up with the international cable system of the Eastern Extension and Great Northern Companies.

Canterbury.—The consulting engineer (Mr. Robert Hammond) has been requested to report as to further extensions of the electricity generating plant necessary and the probable cost. An order has been placed with the Western Electric Co. for an extension of their cable contract.

Cardiff.—At a meeting of the Electrical committee last week the electrical engineer (Mr. N. Appelbee) reported that the consumption of electric energy had increased to considerably above the maximum of last winter. Provision had been made for a 50 per cent. extra consumption on last year's maximum, and when that was reached, as was anticipated, they would have machinery standing by to provide half as much energy again.

Owing to the increase in the price of coal, the Cardiff Gas and Coke Co. have given notice to terminate their existing agreement for the public lighting on March 25. The town clerk is reporting on the matter, and with a view to increasing the demand for electric current it has been decided to issue circulars pointing out the great advantages of electric light.

Chester.—The Council will promote a bill to reconstruct existing and construct new tramways. The undertaking of the local tramway company has been acquired for £18,000. Power to adopt electric traction will also be sought.

City of London.—At the meeting of the Common Council yesterday (Thursday) the Streets committee presented a scheme for the testing of all electricity meters within the City under the direction of the electrical inspector at the expense of the City of London and the Charing Cross and Strand Electricity Supply companies, each company to contribute, in addition to other expenses, £200 per annum to the Corporation in respect of the electrical inspector's salary. Under these circumstances it was proposed to increase the inspector's salary from £350 to £500 per annum. Under the scheme the Corporation will be relieved of all expenses in connection with the appointment, at present amounting to £350 per annum.

Coburg (Victoria).—The borough engineer (Mr. Pullar) is preparing a report on the question of erecting electricity works.

Colne.—The Technical Schools are to be lighted electrically. The electrical engineer (Mr. A. G. Cooper) recently sent out circulars to ascertain the amount of support likely to be accorded to the proposed electric lighting scheme, and up to the present favourable replies have been received for nearly 3,000 8 c p. lights.

Colwyn Bay.—Owing to the increasing demand for electric current, the engineer (Mr. Jones) has been instructed to prepare plans and specifications for additional plant.

Consett.—The Council have resolved to adopt public electric lighting, and refuse destructor works are to be erected in conjunction with the electricity undertaking. Terms have been come to with the Northern Counties Electrical Supply Co. for obtaining a provisional electric lighting order.

Darlington.—The Light Railway order granted to the Imperial Tramways Co. has now been issued, and the Town Council are dissatisfied with its terms. Objections will be lodged against its confirmation by the Board of Trade.

The Electric Light committee will supply electric current about Christmas.

Derby.—Application has been made to the Local Government Board for sanction to borrow £35,000, the estimated expenditure on electric lighting account during the next two years. The chairman of the Electric Lighting committee (Mr. Butterworth) announced on Wednesday that the revenue from the sale of electric current increased last year by £1,593, or 16½ per cent. Expenditure increased by £1,267, principally owing to the high price of coal. Establishment charges had, however, been reduced, and the committee had been able to pay interest on capital, which now amounted to £105,000, to pay off £2,507 of borrowed capital, and the profit balance was £113. New plant, which would cost £8,650, was urgently required, and extensions of mains would absorb £7,500, whilst a new chimney would also have to be built. The equivalent number of 8 c.p. lamps connected had increased during eight months of the current year by 9,000, compared with an increase of 7,800 during the whole of last year.

Devonport.—The Council have instructed Mr. C. Chadwell to prepare plans for the construction of the St. Budeaux electric tramways, but owing to the pressure of other work, application is to be made to the Board of Trade for an extension of time to construct the lines. The Council have offered to lease the lines to the Devonport and District Tramway Co. for a term of years, at a rental of £50 per mile, with the addition of such sum as is required to pay interest and sinking fund on the cost of construction, and one-third of the sum required for interest and sinking fund on the cost of rebuilding Camel's Head Bridge. The company are also to pay the Corporation's costs in obtaining powers for the St. Budeaux lines, and are to take electric current from the Corporation's mains.

Dudley.—An inquiry was held on Friday into the application of the Council to borrow £10,000 for electric lighting. The consulting engineer (Mr. R. P. Wilson) said the loan was required for the "free" wiring of premises. The Corporation were going to charge 6d. per unit for the first two hours per day, and 1½d. per unit after. Dudley would be the first place in England where so low a price as 1½d. per unit had been charged. At present they were only supplying current for the tramways, the charge being 2d. per unit for the first 150,000 units, and one-tenth of a penny less for every additional 50,000 up to 400,000 units. The tramway to Stourbridge had been at work a year, during which period the consumption had been 196,000 units, and they anticipated a demand of 270,000 units for lighting. There was no opposition.

Dudley-Cradley Electric Tramway.—Owing to the non-arrival of the Board of Trade certificate, traffic on the new Dudley-Cradley Heath electric tramway has been suspended.

Eccles.—The Council have decided to promote a bill for, *inter alia*, powers to double and alter the existing tramways, to construct new lines, and to adopt electric traction.

Electricity in Mining.—At a meeting of the Mines Drainage Commissioners at Dudley the chairman (Mr. J. B. Cochrane) regretted he could not speak more encouragingly of the Tipton mining district. They looked to shortly having electric pumps at work, and to mine-owners opening out their mines. When these advances were made, there would come a good time for South Staffordshire mining.

At a meeting of Rezende (Ltd.) on Wednesday the chairman (Mr. N. Brown) said the Umtali Falls (Rhodesia) were near their mine, and from the outset it had been the directors intention to use the power there available, but owing to conflicting claims they did not feel it safe to order the necessary machinery, but on the day that matters were put on a proper business footing with the Chartered Company they immediately proceeded to order the water power and electrical plant, the specification and tenders for which had long before been obtained in anticipation. They had the right to half the power of the Falls, and the plant, which was now in course of shipment, was calculated to deliver about 150 H.P. effective at the mine. Until the plant was erected and started they could not bring their additional 10 head of stamps into use. Two Pelton water wheels would drive a two-phase electric generator, which would produce current at 2,500 volts. This current would be conveyed about 1½ miles to the mine, where it would be utilised in driving the motors, working the mill, rock breakers, cyanide works pump, mine pump, hoisting gear, rock drills and other machinery, besides supplying electric light. Until this installation was complete they were dependent on wood and oil fuel. The plant ordered had now been practically all shipped, and some of the material was actually in Umtali.

Digitized by Google

"**Engineering Magazine.**"—The October issue contains articles on "Electric Power Distribution in Great Britain," "The Commercial Organisation of the Machine Shop," "Centralisation of Steam Condensing Plant," and "The 1,000 miles Automobile Trials."

Fatality.—On Saturday last the first fatal accident on the Central London Railway occurred. A conductor on one of the trains named Field had occasion to take exception to a passenger smoking in a non-smoking carriage, and, in order to discover whether the smoking was still going on, very incautiously opened the gates which divide the carriages, put his head out into the tunnel to look through the side window, and in doing so his head seems to have caught a projecting lamp, and he was rendered insensible. His body then fell on to the permanent way receiving numerous injuries which proved fatal. A verdict of accidental death was returned at the inquest held on Wednesday. Field's action was in direct contravention of the railway company's regulations, which prohibit the opening of a gate whilst the train is in a tunnel. In future the ends of the carriages are to be fitted with glass panels, and the probability of any such accident occurring will be reduced to a minimum.

Fifteen Years' Inland Telegraph Messages —The number of messages forwarded from telegraph offices of the United Kingdom for the year ended March 31, 1886, was 39,146,283. In 1890 this number had increased to 62,368,034, in 1895 to 71,589,064, and in 1900 to 90,415,123, the annual increase having been continuous throughout.

Finchley.—The Council have declined to join the local authorities of Enfield, Edmonton, Wood Green, and Southgate in the suggested joint electricity supply scheme for these districts. The Council are willing to take a supply of electricity in bulk on suitable terms when available.

Folkestone.—The Council have decided to apply for parliamentary powers to construct electric tramways at an estimated cost of about £93,000. It is proposed to adopt the conduit system in the centre of the town and the overhead system in the outskirts.

Glossop.—The Urban Electric Supply Co., which recently acquired the provisional electric lighting order from the Council, has entered into a supplementary contract in regard to the construction of electric tramways in the town.

Harrogate.—Sanction to borrow an additional £10,000 for electric lighting extensions has been obtained by the Council.

Hastings.—Extensions of the electric lighting mains, estimated to cost £1,149, have been sanctioned by the Council, and application has been made for sanction to borrow this amount.

Heckmondwike.—Sanction to a loan of £14,343 for electric lighting has been approved by the Council.

Hexham.—A special meeting of the Council has been called to consider the electric lighting question.

Irvine.—A proposal "that steps be taken to ascertain the capabilities of the Burgh's coalfields for the generation of electric current" has been remitted to a committee of the whole Council.

Islington (London).—Arc lamps are to be erected from Hornsey-road, along Benwell-road, to Drayton-park, at a cost of £1,450.

Light Railway.—The Sheerness and District Light Railways Order has been submitted to the Board of Trade for confirmation. Objections by 27th inst.

Lincoln.—The Corporation are advertising for tenders for a dry-back, marine-type boiler and a high-speed engine coupled to a continuous-current dynamo, a motor and centrifugal pump, and accessories. Tenders have to be in by Nov. 15.

On the recommendation of the Electricity Works committee it has been decided to grant the city electrical engineer (Mr. C. S. Vesey Brown) a gratuity of 100gs. for his services in connection with the Corporation (Tramways) Act (1900).

At the last meeting the chairman of the committee (Ald. Harrison) said the increase in the amount of current supplied during the last quarter was 40 per cent. over the corresponding quarter of last year.

Liverpool.—The School Board have decided to wire the Hightown Truant School for the electric light at a cost of £749.

London County Council.—At Tuesday's meeting it was agreed to loan Battersea £20,000 for electric lighting; £3,187 to Islington for electricity meters; and £5,147 to Battersea for arc lamps and standards.

On the recommendation of the Building Act committee, approval was given to plans for the extension of the Hampstead electricity generating station, and for the construction of a generating station for the Bermondsey Vestry.

The Highways committee, in their report, point out that for the first time the result of the Council's working of its own tramways in South London could be noted, the result being in every way satisfactory. Traffic receipts had exceeded by £8,000 those of the most successful year of the London Tramways Co., whose undertaking the Council had purchased. The system of ½d. fares had been largely extended, the service generally improved, and a 60-hour week established for the employés, and, in spite of the expenditure incurred in connection with these matters, the budget for the present year showed that £42,000 was available for relief of the rates.

Long-Distance Telephony.—H.M. Consul-General at Christiania, Norway, has forwarded to the Foreign Office a despatch reporting that telephonic communication has been established between Christiania, Göttenburg, Malmö and Copenhagen. The rates for conversations between these Danish and Norwegian cities are as under: First zone on Danish and Norwegian exchanges east of Porsgrund and south of Lillehammer, 2 kroner, and 50 ore extra for each zone beyond the first in each country, for every ordinary conversation of three minutes' duration. Express and prepaid conversations are charged thrice these rates. 20 ore extra is charged for sending a messenger or a summons to a particular individual.

Lowestoft.—The Council have decided to promote a bill for powers to construct electric tramways. This decision has been come to owing to the refusal of the Board of Trade to insert in the Royal Plain-Kessingland Light Railway order granted to the National Electric Traction Co. the terms of an agreement between the Council and the company entered into in May last. In dealing with this question at the last meeting of the Council the mayor stated that a great deal of negotiation had taken place between the Council and the promoters ending in an agreement which the Council considered vital in the interests of the Corporation, and as the Board of Trade had not seen their way to incorporate the terms of that agreement in the order the Council had no other course but to give the company notice to determine that agreement, which would leave the Council at liberty. Of course, if the Council constructed the tramways on their own account, they might expect opposition from the company, who, through no fault of their own, lost the benefit of their order. Therefore, he thought the clause of the resolution in regard to the leasing to the company of the tramways in the borough was very fair and honourable, and if carried was likely to terminate in benefit to both parties.

Lytham.—At the Council meeting last week, in answer to a question from Councillor Mellor in regard to electric lighting (the provisional order being about to expire), the chairman (Mr. E. R. Lightwood) explained that they had been so staggered with the estimate placed before them by their consulting engineer that they considered they had better let the matter drop for the present.

Manchester Post Office Fire.—It is gratifying to learn that, notwithstanding the friction existing between the National Telephone Co. and the Post Office, the former tendered very acceptable assistance to the Manchester postal authorities on the occasion of the big fire which occurred at the postal telegraph office a few days back. For this good service the Postmaster-General has officially expressed his appreciation. By the aid of the company the work of maintaining and restoring telephonic and telegraphic communication between Manchester and the rest of the world was materially facilitated.

Matlock Bath.—The Northern Counties Electricity Supply Co. have submitted terms to the Council for the erection of electricity works.

Middlesbrough.—A meeting of the Electric Lighting committee was held last week to consider the positions of the 40 arc lamps which it is proposed to erect in the principal thoroughfares. The consulting engineer (Mr. Hammond) submitted plans. The 40 arcs are to displace 147 existing gas lamps. Twenty of these arcs are to be switched off at midnight, and the total estimated cost is £800 per annum, against the present cost for gas by the 147 lamps of £782.

Moffat (N.B.).—A committee consisting of Messrs. Brown, Easton and Stevens has been appointed by the Burgh Commissioners to consult Mr. W. J. G. Forman in regard to a scheme for the erection of electricity works in the district. In a preliminary report Mr. Forman puts the estimated cost at about £2,500, and proposes to utilise water power in the generation of current.

Molesey (Surrey).—The Council has obtained a report from Mr. A. T. Snell on the proposals of Edmundson's Electricity Corporation in regard to establishing electricity works. Mr. Snell is of opinion that the offer of the company is a fair one, except in one provision, the effect of which would be to prevent the Council from putting down their own plant within 21 years. The advantages to the Council, if the offer were accepted, Mr. Snell summarises as under: (1) No immediate outlay of capital, and no immediate responsibility; (2) the maximum price for street lighting, 2½d. per unit, is lower than the Council could themselves generate current for some years to come, having regard to the relatively few street lamps (about 200) and the probable small demand for private supply during the first few years; (3) the maximum price for private lighting, 7d., 4d., and 2d. (on the maximum demand system) is fair to commence with, and will probably work out on an average to about 6d. per unit, which is cheaper than gas at 4s., light for light. The revenue earned by the company from the district would probably be insufficient to pay a dividend on the capital for some years, and as 11 districts were proposed to be supplied, half of which, in Mr. Snell's judgment, offered more remunerative fields than East and West Molesey, it was possible that this district might suffer for some time from an inefficient or defective supply, due to want of

Digitized by Google

plant at the power station. Granting the choice of company supply, Mr. Snell suggested a number of conditions for inclusion in any agreement between the Council and the company. After discussion the Council decided to apply for a provisional order as suggested.

Municipal Telephony.—The Eastbourne Town Council have decided to apply for a licence to establish a municipal telephone exchange.

Nelson.—The Council have notified the Burnley Tramways Co. of their intention to purchase so much of the company's undertaking as lies within the borough.

Northampton.—It has been decided by the Council to apply for parliamentary powers to construct and work electric tramways in this district.

Oldham.—The Electric Lighting committee recommend that application be made for sanction to borrow £157,000 for the erection and equipment of a new electricity station at Greenhill for the purpose of supplying electric current for lighting, power and traction. At last week's Council meeting the chairman of the committee (Ald. Harrop) said the old station was started in a state of fear for the purpose of keeping companies out of the town, and not for the love of the work. Consequently, the present site was very cramped, and was a great inconvenience and expense. Seeing the success of the work, the committee thought it best to start in an adequate way, and they would provide for the next 20 years by the new works and system of working now proposed. The price for current was now one of the lowest in the country, being 3·41d. per unit for lighting and 3·39d. for other purposes. The total of the various estimates for the electric extensions amounted to £156,510. The recommendation was agreed to.

Paisley.—At Tuesday's meeting of the Council a statement was presented dealing with the financial condition of the electricity department. The capital expenditure to date is £94,832. 15s. 1d., after allowing £500 for contingencies, or £14,832. 15s. 1d. in excess of present borrowing powers. No allowance has, however, been made to cover the cost of laying additional mains and connections. Mr. J. Balderston Whyte, C.A., who presented the report, stated that three engines supplied to the station by Messrs. S. Z. de Ferranti (Ltd.) are to be removed, and two engines are to be supplied of equal capacity without further expense to the Corporation.

Pietermaritzburg (South Africa).—The Municipal Council have resolved to construct a system of electric tramways. The work will be carried out under the superintendence of the borough electrical engineer. The gauge of the track is to be 4ft. 8½in., and the pattern of car chosen is the 8-wheeled double-deck. Electric current will be supplied by the electric light department.

Pleasley (Notts.).—An offer of the Shirebrook Colliery Co. to light the district by 32 c.p. incandescent electric lamps, at £2 per lamp per annum is to be considered at the next meeting of the Parish Council.

Poplar.—The official opening of the electricity station built by the Poplar District Board of Works took place on Monday last. Poplar is one of those districts which has held a provisional order for many years, and would probably not have made use of it even now had not a company applied for powers in the same district. The order dates from 1893. The works have been designed by Mr. A. Blackman, who remains as resident engineer. Mr. Blackman who was formerly Corporation electrical engineer at Aberdeen, a "Kennedy" station, has adopted the pressure of 230 volts on the three-wire system. This is somewhat surprising, as, so far, the load on the station is chiefly for public lighting, and the area of the district amounts to 5 square miles. For the street lighting there are 165 10-ampere and 7·5-ampere arcs and 200 16 c.p. incandescents. The mains are B.I.W. lead-covered cable laid in ducts of U-section, with spigot and socket joints and brick covers. The equipment of the works themselves includes four Babcock-Wilcox boilers, with an aggregate horse-power of 1,200, and four Belliss triple expansion engines driving four-pole 150kw. Mather and Platt machines. Both condensing and feed-water is obtained from a canal, and the pumps of the surface condenser are driven off the crank shaft of the engines. The battery is made up of 200 15-plate Hart cells, with a capacity of 600 ampere-hours and for a maximum discharge current of 160 amperes. The "Wright" system of charging is employed, with rates also on the "Wright" system for power supply, and a system of "free" wiring has been adopted in order to encourage private consumers.

Redcar.—The Council have already decided to embark in municipal electricity supply, and they are now recommended to obtain powers for the construction of electric tramways between Redcar and Saltburn. Should the Council decline to take this step a company will proceed to obtain powers.

Rochdale.—Electric current was supplied to some of the shops in the principal thoroughfares on Wednesday evening. There are at present 35 customers, and the Town Hall, Technical School, Central Board School and the new Board School at Hamer Bottoms are being wired. The supply pressure is 220 volts, and the charge is 6d. per unit for lighting and 3d. for power.

Ryde (I.W.).—Sanction to a loan of £30,000 for 25 years has been obtained by the Council.

Sheffield.—In our issue of Sept. 7 we gave an abstract of the report of the city electrical engineer (Mr. S. E. Fedden) on the position of the electricity undertaking and of the steps to be taken to meet the anticipated increased demand for current for power. Mr. Fedden recommended that certain modifications of the existing system should be effected, and reported that to carry out his proposal, the following additional expenditure would be necessary for 1901: Additions and alterations in boiler house, £3,500; 2,000kw. of new plant complete, £23,000; additional feeders, £5,000; contingencies, £1,995; total, £41,895. This extension would fill up the present station, and Mr. Fedden therefore recommended that the erection of a larger station should be taken in hand without delay. The Council's consulting engineer (Mr. Robert Hammond), who was instructed to consider this report, now announces that he is in complete agreement with Mr. Fedden, and considers that hitherto municipal electricity works have been started on far too small a scale. He is in entire accord with Mr. Fedden as to the advisability of putting the works in a position to supply electric energy at a low rate for motive power. Mr. Hammond states that, as consulting engineer to many of the towns affected by the bills promoted during the past session of Parliament he had the advantage of hearing the whole of the evidence tendered by the promoters, and of gathering the feeling of the House of Commons Committee on these and similar schemes, and he was glad to say that the Committee fully affirmed the principle of "peaceable possession for good behaviour." The Committee laid down the precedent that "where a local authority was able and willing within a reasonable time and on reasonable terms to afford a supply of electrical energy for power purposes it should not be competed with by a company." While not sharing the opinion of the promoters of the power bills that electrical energy will be adopted by large steam users in preference to steam, Mr. Hammond was decidedly of opinion that there was a very large field for the substitution of electrical energy for steam in a host of small industries, and that opinion had recently been confirmed by a visit which he had made to the principal cities on the Continent. That visit afforded him an opportunity of considering the relative merits of polyphase and continuous-current motors, and excellent work was being done by the use of the former. In those circumstances Mr. Fedden did well to consider whether the central area should be supplied by continuous currents or whether certain modifications could be made in the existing system in order to avoid the heavy capital outlay entailed by conversion. With the data before him last year, it certainly seemed to Mr. Hammond desirable to consider carefully the advantages attaching to a partial conversion of the system to continuous-current supply. He had on the present occasion had fuller data laid before him, and he had also had the advantage of a lengthy conference with Mr. Fedden, with the result that he was able to state his complete conformity with Mr. Fedden's proposed plans. Mr. Hammond states that the introduction into Sheffield of the sub-station system, which had been found satisfactory in Leeds, would largely diminish the losses in distribution. He was also in agreement as to the desirability of reducing the periodicity of the present system from 100 to 50. As the earliest possible delivery was highly important he advised the Council to endeavour to secure one or, if possible, two of the sets at present in use at the Paris Exhibition. With regard to the estimated expenditure of £41,895, he understood that the figures were based upon actual quotations, and, roughly checking them, they appeared to him to be well within the mark. To those figures, however, must be added the cost of substituting the sub-station for the house-to house transformer system, and also those incidental to the changed periodicity as far as the tranformers were concerned. He would suggest, also, that in applying to the Local Government Board provision should be made for a capital outlay on motors, in order to put the Corporation in a position to let these machines out on hire, a plan which had met with great success at Bradford. Finally, he agreed that the carrying out of Mr. Fedden's scheme would put their present works on a footing to give the best possible results as a whole. Mr. Hammond's report was considered at the last meeting of the Electric Light committee, but nothing was decided in regard to it. It was reported that the deputation appointed at the last meeting had concluded that it was unnecessary to make the proposed visit to Paris, and that Mr. Fedden had gone alone to the Exhibition, and also to Nuremburg and Frankfort.

South Shields.—In a report to the Electric Lighting committee the borough electrical engineer (Mr. J. A. Jeckell) states that as the distributing mains are now laid in a large number of streets, it is advisable to light all the streets as an additional source of income, and he suggests that if the Town Improvement committee would light all the streets electrically where low-tension mains are laid the price of current might be reduced to the following: 2·16 c.p. lamps, 1s. per week; 2·25 c.p. lamps, 1s. 6d. per week; 3·32 c.p. lamps, 2s. per week. The price for arc lamps to be reduced to £20 per annum when 100 or more are taken. The committee resolved that

Digitized by Google

these prices be adopted on the Town Improvement committee agreeing to light electrically all the streets where low-tension mains are laid.

Stafford.—An inquiry will shortly be held into the application of the Council to borrow £10,000 for electric lighting extensions.

Stirling.—The County Hall is to be wired for the electric light at a cost of £160.

Stirling and Bridge of Allan Tramways.—In a report just issued by the directors of the Stirling and Bridge of Allan Tramways Co. (Ltd.), it is stated that a provisional agreement has been entered into with the British Electric Traction Co., and in consequence negotiations are proceeding with the local authority in regard to extensions and the adoption of electric traction.

Stratford-on-Avon.—As the Council have decided to apply for a provisional order, the application of the United Electric Light and Tration Co. is to be opposed.

Sunbury.—The Twickenham and Teddington Electric Supply Co.'s application for a provisional order is not to be opposed by the District Council.

Swindon.—Application for sanction to a loan of £31,000 for electric lighting is to be made.

Warwick.—The British Electric Traction Co. notify that they will apply for a provisional electric lighting order.

Waterloo (Liverpool).—A proposal by a syndicate to construct a pier, together with an electric tramway about three-quarters of a mile in length, is under the consideration of the Health committee of the Council.

Watford.—Messrs. Preece and Cardew have been appointed consulting engineers to examine and report upon the existing electricity works. In a preliminary report by Major Cardew, the Council were recommended to obtain an additional Babcock-Wilcox boiler, a feed water-heater and softener, as proposed by their electrical engineer (Mr. Colebrook), at an estimated cost of £1,700. This recommendation has been approved, and a tender from Messrs. Babcock and Wilcox has been accepted.

West Bromwich.—As announced in our last issue the Electric Lighting committee have decided, on the recommendation of their consulting engineer (Mr. Robert C. Quin), to fix the charge for electric current for lighting purposes at 6d. per unit until an equivalent of 100 hours' maximum demand has been reached in each quarter, and 2d. per unit after. Current for power is to be supplied at 3d. per unit until an equivalent of 78 hours' maximum demand has been reached in each quarter, and 1d. per unit after. The "free" wiring system is to be adopted, the cost of wiring to be spread over 10 years. The following table show the estimated cost of wiring, and the annual purchase payments:—

Number of lights.	Estimated cost of wiring.	Estimated annual payments.
5	£4 1 10	£0 8 2
8	6 10 11	0 13 1
10	8 3 7	0 16 4
14	11 9 1	1 2 11
20	16 7 4	1 12 9
35	28 12 6	2 17 3
40	32 14 7	3 5 6
48	39 5 6	3 18 7

Consumers who pay the whole of the annual payments within the first year will be allowed 10 per cent. discount; during the second year 7½ per cent.; during the third year 5½ per cent.; during the fourth year 2½ per cent.; after the fourth year no discount. The committee further recommended that contracts be entered into for the supply of materials for wiring houses, and for the labour necessary for carrying out the work. It has also been resolved to hire out motors, but the conditions are still under consideration. An animated discussion arose on the report, which was eventually adopted. Application has been made for sanction to borrow £10,000. Owing to the large demand for current for power the station buildings are to be extended.

West Yorks.—A scheme for the erection of electricity works for supplying current for lighting and power in the districts of Slaithwaite, Linthwaite, Marsden, and Holmfirth is being prepared by Mr. A. H. Gibbings. A conference of representatives from the districts interested was held last week at Huddersfield, when Mr. Gibbings submitted particulars. It is probable that parliamentary powers will be applied for.

Whitby.—At a recent meeting of the Council contracts were let for the supply of electricity generating plant, and it was decided to advertise for tenders for a loan of £9,000 to defray the cost.

Worksop.—Sanction to a loan of £15,570 for electric lighting has been received by the Council, the period of the loan being 25 years.

Electro-Harmonic Concert.—Members and their friends are reminded that the first (smoking) concert takes place this (Friday) evening at 8 o'clock, at the old haunt, St. James' Hall Restaurant, Regent-street, London, W. Mr. J. Wilson Swan, F.R.S., will preside.

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers, or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London:—

"The Art of Electrolytic Separation of Metals."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free. The author treats fully both the theoretical principles of the art of electrolytic separation of metals and the practical rules and details of technical application on a commercial scale. The work is adapted to the use of the manufacturer as well as the student.

"Electromagnetic Theory."—By Oliver Heaviside. *Vol. I.*, 12s. 6d. *Vol. II.*, 12s. 6d.

"Electrical Testing for Telegraph Engineers."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. Demy 8vo, fully illustrated. 10s. 6d., post free.

"Wireless Telegraphy: Signalling across Space without Wires by Electric Waves." A Review of the Work of Hertz and his Successors.—By Dr. O. J. Lodge, with a large number of illustrations, bringing this latest application of electrical science quite up to date. New and Enlarged Edition, 5s. nett. *Now ready.*

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. *New and Cheaper Edition*, 6s., post free.

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

TENDERS INVITED.

Cardiff County Borough invites tenders for slow-speed vertical engines, slow-speed converters, and boilers and economisers, &c. Specifications can be obtained from the tramways engineer (Mr. Arthur Ellis), Old Post Office-buildings, Cardiff, and tenders must be sent to Mr. J. L. Wheatley, town clerk, Town Hall, Cardiff, by 23rd inst. An advertisement gives further particulars.

Bradford Corporation invite tenders for a 30-ton electric travelling crane for their Valley-road electricity works. An advertisement gives further particulars, and specifications may be obtained from the city electrical engineer (Mr. R. A. Chattock). Tenders to town clerk (Mr. Frederick Stevens), Town Hall, Bradford, before 25th inst.

Belfast Gas and Electric Light committee invite tenders for steam pipes, pumps, &c., condensing plant, boilers, mechanical stokers and superheaters, coal and ash-conveying plant and switchboard extensions. An advertisement gives further particulars, and specifications may be obtained from the city electrical engineer (Mr. Victor A. H. M'Cowen). Tenders to town clerk (Sir Samuel Black) by noon Nov. 23.

The directors of the *Acme Wood Flooring Co. (Ltd.)* require tenders for the electric lighting of their mill premises at Victoria Park, London, N.E. Specification, &c., may be obtained at the offices of the consulting engineers, Messrs. Taylor and Field, 14, Victoria-street, Westminster, S.W. An advertisement gives further particulars.

The Directors of the *Great Western Railway Co.* invite tenders for telegraph and other stores for twelve months from Dec. 1st next. Samples and patterns may be seen at Swindon from 9th to 18th inst., and specifications may be obtained at office of stores superintendent. Tenders to secretary (Mr. G. K. Mills), Paddington Station, London, W., by 22nd inst.

The *Secretary of State for India* invites tenders for (1) a complete electrical installation for supplying power to a factory from a waterfall 3 miles distant, and (2) a complete hydraulic installation to develop about 500 H.P. Tenders to India Office, Whitehall, S.W., by 2 p.m. Oct. 16.

Bermondsey (London) Vestry invite tenders for steam, feed exhaust, and drain pipes, feed pumps, water storage tank and sundry ironwork, and also for steam dynamos, battery charging motor, booster, and balancer. Tenders to vestry clerk by Oct. 15.

The *Postmaster-General* is inviting tenders until 22nd inst. for red fir telegraph poles and for creosoting. Forms of tenders from Mr. Chas. E. Stuart, controller of stores, General Post Office, London.

London County Council require tenders for 12 months' supply of engineers' goods and electrical stores. Tenders to clerk, County Hall, Spring-gardens, S.W., by 29th inst.

Whitechapel (London) Electrical committee require tenders for a hand-driven overhead travelling crane for their electricity station. Tenders to chairman must be delivered by noon 23rd inst.

Digitized by Google

Sunderland Corporation invite tenders for 24 car bodies, trucks, and electrical equipment. Tenders to chairman Tramways committee by noon Oct. 15.

Maidstone Corporation invite tenders for surface condenser and feed pumps. Tenders to town clerk before 10 a.m. Oct. 16.

The Streets committee of *City of London* Corporation are again inviting tenders for a mechanically-driven dust cart. Tenders to town clerk (Sir J. B. Monckton) before Nov. 10.

Aberdeen Town Council invite offers for 25 electrical tramcars, and for equipments for six horse cars about to be converted. Tenders before noon of Oct. 17.

Aberdeen Council require tenders for materials and construction of works in connection with the permanent way of their new electric tramways. Tenders to burgh surveyor by 18th inst.

Glasgow Corporation require steel straight track and curved rails and fish-plates. Tenders by 23rd inst.

Dundee Gas Commission require tenders for three steel water tanks for their electricity works. Tenders to clerk by noon Oct. 15.

French Post and Telegraph authorities invite tenders until 18th inst. for 850,000 porcelain insulators. Tenders to le Sous-Secretariat d'Etat des Postes et des Télégraphes, 103, rue de Grenelle, Paris.

TENDERS RECEIVED AND ACCEPTED.

The War Office have accepted the tender of Messrs. Pritchetts and Gold for supplying and fixing storage batteries and stands for each of the three Spithead forts. There will be 33 cells at the Spitbank fort and 44 at both Horses and Noman's Land forts, and in all cases the boxes will be of teak lead-lined.

The contract for steam dynamos, balancers and boosters for the new Worksop electricity works has been awarded to Messrs. Witting Bros. (Ltd.), 49, Cannon-street, E.C. The generating sets consist of Messrs. Witting's standard multipolar machines direct-coupled to Messrs. E. Scott and Mountain's high-speed engines.

Tunbridge Wells Council have accepted the tender of Mr. J. Jenkins for the erection of a brick chimney shaft at the electric lighting station for £3,835. 2s. 4d.

Heckmondwike Council have accepted the tender of Mr. G. F. Cooke for arc lamps and posts in place of Messrs. Veritys, who declined to accept the contract owing to an error in tendering. As Messrs. P. C. Middleton & Co. (Ltd.), who had obtained the contract for generating plant, have gone into liquidation, the consulting engineer (Mr. W. C. C. Hawtayne) has been instructed to communicate with the next three lowest tenderers.

Stafford Council have accepted the tender of the Electric Construction Co. for re-winding the armatures and field coils of the dynamos at the electricity works at £322; and in consequence of the insulation of the feeder and distributing cables having been found to be defective, the necessary work for re-insulating and re-laying the cables on Callender's solid system is to be carried out at an estimated cost of from £2,300 to £2,500.

Wigan Corporation have accepted the following tenders for the supply of electric tramway plant:—

Estler Bros., steel poles and section pillars.
Robt. W. Blackwell & Co., flexible bonds and castings.
Bergtheil and Wilson Young, overhead construction material.
Naylor Bros., bracket arms.

The contract for trolley wire has not yet been let.

Ayr Corporation have placed an order with Messrs. Siemens Bros. & Co. for three sets of continuous-current generating plant at £5,862 for lighting, and with Messrs. D. Bruce Peebles & Co. for two traction generators, each of 200kw., at £4,380 for the tramways.

Glasgow Tramways committee have arranged with Messrs. Macartney, M'Elroy & Co. to proceed at once with the erection of the overhead work for the tramway extensions in Alexandra-parade, Cumbernauld-road, Keppochhill-road, and Great Western-road, and with the Lorraine Steel Co. to proceed with their contract for the special track work.

The contract for the wiring and fitting of the Horton Asylum, Epsom, for the electric light has been let to Messrs. F. Troy & Co.

Stockport Town Council have accepted the tender of Messrs. Dick, Kerr & Co. for 20 top-seat cars at £675 each.

The London County Council have entered into a three years' contract with Mr. F. J. Coleby for the maintenance of the electric bells at the chief fire station, at £315 per annum.

Watford Council have accepted the tender of Messrs. Babcock and Wilcox for a water-tube boiler at £930.

APPOINTMENTS VACANT AND FILLED.

Motherwell Corporation invite applications for the position of burgh electrical engineer. An advertisement gives further particulars, and applications must be sent to the town clerk (Mr. James Burns) by 20th inst.

Bray (Ireland) Council notify in an advertisement that they will, at their meeting on 22nd inst., elect an electrical engineer to take charge of their electricity works. Applications to clerk (Mr. P. MacDonnell), Town Hall, Bray.

A mechanical engineering assistant is required for the office of a municipal engineer of a large town in the Midlands. Candidates must have had experience in electric tramway construction and steam practice. Applications by 26th inst. See advertisement.

Leyton District Council require a shift engineer for their electricity department. An advertisement gives further particulars, and applications must be sent to the engineer and manager (Mr. F. Harman Lewis), Cathall-road, Leytonstone, by 20th inst.

A first-class mechanical engineer, a shift engineer, a sub-station assistant, and a time and store keeper are required for a continuous-current electric lighting station near London. See advertisement.

A laboratory assistant in electrical engineering is required for the Municipal Technical School, Manchester. Applications to director (Mr. J. H. Reynolds). See advertisement.

A switchboard attendant is required for a London low-tension supply station. See advertisement.

West Bromwich Corporation require a borough electrical engineer. Commencing salary, £250 per annum. Applications to Mr. Alfred Caddick, Town Hall, West Bromwich, by 17th inst.

Belfast Corporation require a principal for their proposed technical institution. Salary £600 per annum. Applications by 22nd inst.

A head master is required for the Walthamstow Technical Institute. Applications to clerk to District Council by 26th inst.

Mr. C. S. Davidson, of Leyton electricity works, has been appointed clerk of works to superintend the laying of electric lighting mains, &c., at Barnes.

Mr. J. Erskine Murray, D.Sc., F.R.S.E., of the Marconi Wireless Telegraph Co., and formerly of the Heriot Watt College, Edinburgh, has been appointed lecturer and demonstrator in physics at University College, Nottingham.

Mr. G. A. Bruce has been appointed resident electrical engineer to the borough of Lowestoft at a salary of £200 per annum.

Mr. Gardiner has been appointed manager of the telephone department of the Tunbridge Wells Town Council at £156 per annum.

Mr. Bolam has been appointed assistant engineer at the Bristol electricity works, vice Mr. Dowson, resigned.

Mr. J. R. P. Lunn, of Huddersfield, has been appointed borough electrical engineer at Darlington.

Mr. H. W. Clayden, clerk of works under the consulting engineer (Mr. Robert Hammond), has been appointed resident electrical engineer at the Middlesbrough electricity works.

Mr. C. C. Atchinson, at present clerk of works, has been appointed resident electrical engineer at the Rochdale electricity works at a salary of £200 per annum.

BUSINESS NOTICES.

We have received a communication from Messrs. Polland & Co., 5, St. Nicholas-buildings, Newcastle-on-Tyne, intimating that arrangements have been completed for the disposition of the business to the Union Cable Co., Ltd., 23, College Hill, Cannon-street, London, E.C., as from Aug. 24 last. Debts due to Messrs. Polland & Co. will be received by the Union Cable Co., and debts due by Messrs. Polland & Co. will be discharged from 23, College Hill, Cannon-street, E.C.

BANKRUPTCIES, LIQUIDATIONS, &c.

Wm. Haines, electrician, &c., 261, Bury New-road, Whitefield, Lancs., has been adjudicated bankrupt.

In the bankruptcy of T. W. Greaves and W. G. Randall (lately trading as T. W. Greaves & Co.), electrical engineers, &c., 130, East India Dock-road, London, E., and Greenwich, the first meeting of creditors will take place on 18th inst., and the public examination on Nov. 15, at Bankruptcy Buildings, W.C.

An amended notice in the *London Gazette* states that the first and final dividend payable in the bankruptcy of B. Symmons, electrical engineer, Brighton, is 2s. 5½d. and not 2s. 8½d. as previously announced.

Official notice is given that the liquidator (Mr. J. D. S. Bogle, 91 and 93, Palmerston-buildings, E.C.) in the liquidation of the London Metallurgical Co. (Ltd.) has been released.

The Land and Water Electric Power Syndicate (Ltd.) is to be wound up voluntarily. Mr. S. B. Saunders, Bush-lane House, London, E.C., and Mr. J. B. Childe, Bradford and London, are joint liquidators, with Messrs. Hutton, Firth and Ingham as a committee to assist the liquidators.

The Aluminium Co. (Ltd.) is being wound up voluntarily, and Mr. P. S. Court, 13, Abchurch-lane, London, E.C., is liquidator.

Digitized by Google

Plant for Sale.—A 1,200 H.P. three-phase generator, at present in operation at the Paris Exhibition, is offered for sale. An advertisement gives further particulars, and offers must be addressed to "L. T." 815, c/o Haasenstein and Vogler, Berlin, W. 8.

Oldham Electric Light committee invite tenders for two 40kw. shunt-wound dynamos and a spare armature, which will be for disposal in December next. An advertisement gives further particulars, and offers must be sent to the superintendent (Mr. Arthur Andrew), Gas and Water Offices, Oldham.

Telegraph Stores Sale.—The Postmaster-General invites tenders for the purchase of old stores, including about 40 tons of gutta percha, 90 tons of copper wire, plates, &c., indiarubber covered copper wire, tools, &c. Tenders by 10 a.m. 18th inst.

Parsons' Turbo Generators and Alternators.—A new pocket list of the various units of Parsons' turbo-generators and alternators supplied during the past five years or now on order is issued by Messrs. C. A. Parsons & Co., and can be obtained on application. An illustration is given of the 1,000kw. turbo-alternator supplied to the municipal authorities of Elberfeld, Germany. Altogether about 150 units of this type of plant have been supplied for lighting, power and traction. The largest customer in the list for this type of plant is the Metropolitan Electric Supply Co., who have 20 machines installed, the Newcastle and District Electric Lighting Co. being a good second with 11 machines, Blackpool Corporation following with eight.

Brush Traction Trucks.—The Brush Electrical Engineering Co. inform us that plant has been put down at the Falcon Works, Loughborough, for the manufacture of traction trucks, this being the first attempt made in this country to manufacture these trucks. Three standards have been adopted which are calculated to cover the general needs of electric traction. These standards comprise the four-wheel single type, the four-wheel bogie type and the maximum traction type. The special shop which has been equipped for this purpose at Loughborough has been placed under the control of Mr. E. Cook, an engineer who has had large experience in this branch of manufacture in the States.

"Johnson and Phillips" Cables.—Messrs. Johnson and Phillips's Electric Cable Works are issuing a list of standard sizes of conductors for electric supply mains in hanging card form, and copies of this card can be obtained by the trade free on application.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Oct. 3 to Oct. 9, with the ports of destination :—

Africa.—Alexandria, £413; Cape Town, £311; Durban, £2,422; Port Elizabeth, £385 (including £366 telegraph material); Port Said, £20. *Argentina*—Buenos Ayres, £226 (telegraph material). *Australasia*—Brisbane, £30; Fremantle, £66; Hokitika, £11; Lyttleton, £286; Melbourne, £3,210 (telegraph material); Perth, £244; Sydney, £990 (including £139 telegraph material); Wellington, £329. *Belgium*—Ostend, £581. *Brazil*—Rio Janeiro, £47. *Ceylon*—Colombo, £321. *China*—Shanghai, £169. *Denmark*—Copenhagen, £74 (including £44 telegraph wire). *Germany*—Hamburg, £200 (telegraph material). *Gibraltar*, £351 (including £18 telegraph apparatus). *Holland*—Amsterdam, £110; Rotterdam, £250. *Hong Kong*, £488 (including £368 telegraph material). *India*—Bombay, £40; Calcutta, £1,676. *Straits Settlements*—Singapore, £44 (including £30 telegraph material). *Sweden*—Stockholm, £260 (telegraph material). *West Indies*—Jamaica, £112. Total £13,656 against £20,925 in the corresponding week last year (Oct. 4 to Oct. 10).

Fifteen Years' Exports and Imports.—From the recently-issued "Statistical Abstract" for the United Kingdom for the years 1885 to 1899 we find that the *exports* of telegraphic wire and apparatus, electric lighting apparatus and parts thereof, and the *imports* of general electrical goods, were as under :—

Exports.—*Telegraphic Wire and Apparatus.*

1885	£770,054	1890	£1,602,305	1895	£782,375
1886	932,667	1891	1,434,020	1896	857,174
1887	817,385	1892	909,917	1897	997,802
1888	521,055	1893	1,052,887	1893	985,283
1889	1,038,540	1894	1,336,614	1899	1,406,734

Electric Lighting Apparatus and Parts thereof (except Steam Engines).

1885	No record	1890	£281,248	1895	£335,929
1886	88,679	1891	239,194	1896	382,438
1887	99,905	1892	174,641	1897	448,732
1888	166,409	1893	215,366	1898	514,632
1889	211,049	1894	246,354	1899	510,758

Imports.—*General Electrical Goods.*

1885 to 1896. No separate record kept.

1897	£242,185	1898	£367,572	1899	£613,593

Imports of Electrical Goods into the United Kingdom.—The value of the electrical goods and apparatus imported into this country during September was £97,107 against £148,317 in the preceding month. The total for the nine months ended Sept. 30 was £794,699.

PATENT RECORD.

The following list of Applications for Patents and Specifications published has been compiled for this journal by MESSRS. J. C. CHAPMAN and Co., *Chartered Patent Agents, of 70, Chancery-lane, W.C., from whom any available information in connection with Patents, Designs, and Trade Marks may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned Applications are not open to public inspection until after the acceptance of the complete Specification. The names within parentheses are those of communicators of inventions. When complete specification accompanies application, an asterisk is affixed.*

August 9, 1900.

14,288. J. SZCZEPANIK and L. KLEINBERG. London. Improvements in electromagnetic apparatus for jacquards.

14,289. A. W. B. PEARSON. London. Improvements in electric switches.*

August 10, 1900.

14,337. A. BRÜGGEMANN and DEUTSCHE WAFFEN UND MUNITIONS FABRIKEN London. An electric releasing apparatus for pneumatic pressure brakes.

14,347. T. ROBINSON. Liverpool. Hygienic appliance for sound transmitter mouthpieces. (Date applied for under Patents, &c., Act, 1883, sec. 103, Jan. 30, 1900, being date of application in United States.)*

14,354. THE EDISON ORE MILLING SYNDICATE (LTD.). London. Improvement in magnetic separating apparatus. (T. A. Edison, United States.)

14,355. THE EDISON ORE MILLING SYNDICATE (LTD.). London. Improvements in magnetic separating apparatus. (T. A. Edison, United States.)

14,357. K. DE KANDÓ. London. Improvements in electrical contact apparatus.*

14,368. C. DE KANDÓ. London. Improvements in liquid rheostats operated by means of compressed air.*

August 11, 1900.

14,373. H. O. FARRELL. Manchester. Improvements in and connected with electrical fuse boards.

14,383. E. W. LEWIS. Coventry. Improvements in or relating to electrical ignition devices for explosion motors having two or more cylinders.

14,384. W. CARTER and J. BOWRET. Bristol. Improvements relating to rail points and overhead switches in electric tramways.

14,409. J. HARRIS. London. Improvements in electric meters.*

14,420. J. G. LORRAIN. London. Improvements in combined electric meters and demand indicators. (A. Wright, at present on the High Seas.)

14,422. A. H. ADAMS. London. Improvements in switches and apparatus for use in starting and controlling electric motors.

August 13, 1900.

14,449. E. E. BARTLETT. Liverpool. Improvements relating to double-pole, three-way, and similar electrical switches.

14,450. E. E. BARTLETT. Liverpool. Improvements relating to electrical controlling and regulating switches.

14,463. P. SCHOOP. London. Improvements in apparatus for electrolysis.

14,488. R. HADDAN. London. A method of electrically reversing the direction of elevators driven by electricity. (A. Stigler, Italy.)

August 14, 1900.

14,506. A. G. BROOKES. London. Improvements in and relating to dynamo-electric machinery. (C. L. Cotton, United States.)*

14,550. H. H. LAKE. London. Improvements relating to the insulation of electric conductors. (N. Tesla, United States.)*

14,552. H. TUGBY. London. Improvements in conduits for electric conductors, water, or the like.

14,537. J. J. BATE. Liverpool. Improvements in or relating to conduits for electric conductors.

14,558. G. F. R. BLOCHMANN. London. Improvements relating to the transmission and receiving of telegraphic signals.

14,568. R. HADDAN. London. Improvements in toll-collecting machines for telephones. (The American Toll Telephone Co., United States.)

14,582. R. CHAVARRIA-CONTARDO. London. Improvements in and connected with electric furnaces.*

August 15, 1900.

14,608. S. H. HOLDEN and CHAMBERLAIN AND HOOKHAM (LTD.). Improvements in electricity meters.

14,633. P. LAPERTOT, G. VILLARD and L. PIGNAUD. Liverpool. An improved system of electric lighting and apparatus or devices therefor.

August 16, 1900.

14,688. H. E. MOUL. London. Improvements in or connected with incandescent electric lamps.

14,691. S. W. MAQUAY and T. G. CHAMBERS. London. Improvements connected with electric primary batteries for traction purposes.

14,704. C. G. G. BRAUNERHJELM. London. Improvement in transmitters for electrical waves or the like appartus. (Date applied for under Patents, &c., Act, 1883, sec. 103, Jan. 26, 1900, being date of application in Sweden.)

14,712. G. E. GOURAND and H. L. SHORT. London. Improvements in apparatus for recording, reproducing and transmitting sounds.

14,715. W. E. EVANS. London. Improvements in and relating to thermo-electric apparatus. (La Société Ginestes et Cie, France.)

NEW COMPANIES, STATUTORY RETURNS, &c.

ELECTRIC RAILWAYS CO. (LTD.)—This company was registered on Oct. 1, with a capital of £75,000 in £1 shares, to apply for and obtain parliamentary powers, concessions or other rights for the construction of railways, tramways, electrical and other works, electric light installations, &c., and to carry on the business of electrical and mechanical engineers, railway and general contractors, electricians, suppliers of electricity, &c.

CROMPTON & CO. (LTD.)—The annual return to Aug. 12 gives the capital as £162,000, in 54,000 shares of £3 each, all of which have been taken up, and £3 per share has been called up on 52,000 shares.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since July 19, 1900). Price of silver 29 $\frac{5}{16}$d. per oz. (Oct. 11). Consols (2$\frac{3}{4}$ per cent.) 98$\frac{5}{8}$ - 98$\frac{7}{8}$ for money, 98$\frac{1}{2}$—98$\frac{5}{8}$ for account; 2$\frac{1}{2}$ per cent. 96$\frac{1}{4}$—96$\frac{3}{4}$ (Oct. 11). Stocks and Shares Continuation Days, Oct. 24 and Nov. 11; Ticket Day, Oct. 25; Pay Days, Oct. 12 and 26; Mining Share Carry-over Days, Oct. 23 and Nov. 10.

AKKUMULATORENFABRIK AKTIENGESELLSCHAFT BERLIN—HAGEN.—A dividend of 10 per cent. has been declared for 1899-1900, the same as last year.

BRITISH MOTOR TRACTION CO. (LTD.)—At the statutory meeting held last week the chairman (Col. Harris) announced that the reconstruction of the company had been effected. It is stated that numerous actions are pending against alleged infringers of the company's patents.

CUBA SUBMARINE TELEGRAPH CO. (LTD.)—The directors recommend a dividend of 5 per cent. per annum on the ordinary shares (tax free) for the half-year ended June 30.

DIRECT UNITED STATES CABLE CO. (LTD.)—An interim dividend of 3s. per share, tax free (being at the rate of 3 per cent. per annum for the quarter ended Sept. 30), has been declared payable 26th inst.

ELECTRIC RAILWAY AND TRAMWAY CARRIAGE WORKS (LTD.)—The ordinary general meeting of this company was held last week, when the directors reported that the profit shown for the period was £3,914. 4s 11d., and they recommended that this amount be carried forward. All the share capital had been fully subscribed and paid up. Notwithstanding the great pressure in the building and engineering trades, the work of completing the necessary buildings and the installation of the machinery was carried out with a minimum of delay. The works are now in full operation and in a most efficient state. In starting the new industry at Preston great difficulty arose in securing and educating the necessary labour, but the directors are able to announce that there is now a full complement of skilled men, and they look forward with confidence to the result of the working of the current year. Large orders have been received for cars at remunerative rates, and it is hoped that the output of 600 cars per annum mentioned in the prospectus will be exceeded.

GENERAL ELECTRIC CO. (1900) (LTD.)—As announced in our last issue, the prospectus will be issued early next week of a new company, with the above title, formed to take over the General Electric Co. (Ltd.), registered in 1889. The share capital of the new concern is £800,000 in 40,000 5 per cent. cumulative preference and 40,000 ordinary shares, each of £10. There will also be an authorised issue of £200,000 in 4 per cent. first mortgage debenture stock, bringing the authorised capital up to £1,000,000. Subscriptions will be invited for £150,000 debenture stock and £180,000 preference shares, (total £330,000) at par, the venders taking in part payment of the purchase price £50,000 in debenture stock, £70,000 in preference shares, and £250,000 in ordinary shares at par, £130,000, the remainder of the purchase money, being taken in cash. The new company takes over the old company as from March 31, 1900, and the price fixed by the vendors for the business as a going concern is £676,139. 0s. 7d., less debts and liabilities on March 31, 1900, and profits for the year to that date (which are reserved to the vendors), £176,139. 0s. 7d., making the net purchase money £500,000. A certificate of the profits of the old company for the last three years is given by Messrs. Edwin Guthrie & Co., C.A., as under:—

To March 31,	1898	£51,546	10	7
Ditto	1899	57,034	0	0
Ditto	1900	76,804	12	5

or an average of £61,795. 2s. 3d. per annum for the period covered. The nominal capital of the old company was £200,000, of which £177,000 was called up. Of this latter sum £152,000 represents calls received, and £25,000 is considered as paid.

The prospectus states that the present issue will provide £132,841 for extensions of the works and further working capital. The works, offices, and businesses taken over by the new company are set out in the prospectus as follows:—

67, 69, 71, 88, and 92, Queen Victoria-street, 30, Cannon-street, and 56, Upper Thames-street, London, E.C.; 120, Union-street, Borough, S.E.; Victoria Bridge, Manchester, and Peel Works, Adelphi, Salford; 56, Barwick-street, and Ileene Works, Sherlock-street, Birmingham; 71, Waterloo-street, Glasgow; 16, St. Andrew-street, Dublin; and 13, Westgate-road, Newcastle-on-Tyne.

No mention is made in the prospectus of the business of the Incandescent Electric Lamp Co. (Ltd.), with which the General Electric Co. has been so closely identified.

No new blood is introduced on the directorate of the new company, the management remaining in the hands of the old directors, Messrs. G. Byng, M. Byng, H. Hirst, and A. Eckstein. Mr. G. Byng, who has been connected with the company and its predecessors in business since 1880, and who has acted as managing director since the incorporation of the old company in 1889, becomes chairman of the new concern.

The subscription list opens on Tuesday, Oct. 16, and closes at or about 4 p.m. on Wednesday. It is a remarkable sign of the vitality of the electrical industry that a new company with a capital of £1,000,000 sterling can be introduced to the public on such short notice. This is the more surprising, seeing that the prospectus announces that none of the capital has been underwritten; but it may be claimed in this particular instance that the company is old-established and well known.

MUNICIPAL LOAN.—The Reigate municipal issue of £55,000 3 per cent. redeemable stock for electricity works and other improvements has proved a failure. It is said that only eight tenders were received for £6,900.

NEWCASTLE-UPON-TYNE ELECTRIC SUPPLY CO. (LTD.)—At an extraordinary meeting, held last week, the circular which was abstracted in our last issue was discussed. The chairman (Ald. T. G. Gibson) pointed out that the sites selected for the two generating stations were advantageously situated, and in addition to the lighting of the new districts for which they had parliamentary powers the directors were considering the question of constructing electric tramways between Newcastle and North Shields. A private syndicate had been formed which would make application to Parliament for the necessary powers. The various resolutions proposed by the directors were approved.

NEW ST. HELENS AND DISTRICT TRAMWAYS CO. (LTD.)—The first annual meeting was held at Liverpool on Monday. The chairman (Sir John A. Willox, M.P.) moved the adoption of the report, which appeared in our last issue, and said that some time ago the Corporation of St. Helens obtained parliamentary powers to construct electric tramways in the borough and the adjacent districts. They granted a lease of the whole system to their company for 21 years. The Corporation undertook to lay down the rails and the electrical equipment and to supply the motive power, and the company the rolling stock and the staff for working the lines. The rent began to accrue from the date of the lease, but while the rental was thus accruing the electric tramways were not ready for use. At the outset the company was, therefore, at some disadvantage financially. It was seven months after the company came into existence before their first electric section—that between St. Helens and Prescot—was opened. Since then other sections had been opened, and the work was being pressed forward vigorously. At June 30 only about one-half of the tramway system had been completed, but since then other sections had been finished and opened, and they were not without hope that in a comparatively short time fully 20 miles of tramway would be completed. The directors made no complaint against the Corporation of lack of energy in pushing forward the work, as they all knew that there was a great demand for electrical plant and apparatus, and that contractors were unable to finish their work within the stipulated time. The delays at St. Helens might no doubt have arisen from unavoidable causes, and they must endure them with patience, but the result, all the same, had been rather hard on the company. They had been paying rent, providing rolling stock, and incurring all the charges of administration, and had not been able to recoup themselves by receipts from traffic. However, the directors had provided for an ample equipment of cars, and as each section of lines was passed by the Board of Trade the service in that section was commenced the very next day. The cars were roomy, handsome, and well appointed, and had given entire satisfaction to the travelling public, and the service had been maintained on all the routes with regularity. The Corporation's supply of power had been adequate and uninterrupted, and the efficiency of the company's service was undoubtedly largely due to that fact. The receipts on the sections of line now working were large

Digitized by Google

and progressive. The relations between the Corporation and the company were harmonious, and all they now wanted was to get their lines into operation; when that was realised he thought the shareholders would have reason to be satisfied with the result. The report was adopted.

ORIENTAL TELEPHONE AND ELECTRIC CO. (LTD.)—An interim dividend of 2½ per cent. (5 per cent. per annum) on the paid-up capital of the company (tax free) has been declared.

REUTER'S TELEGRAM CO. (LTD.)—An interim dividend at the rate of 5 per cent. per annum (free of tax) for the half-year to June 30 has been declared, payable 13th inst.

SOCIETE ELECTRICITE ET HYDRAULIQUE (CHARLEROI, BELGIUM).—The report of the directors of this company states that the British business, which is entrusted to Messrs. Witting Bros., 49, Cannon-street, London, E.C., has made great progress during the last 12 months. As a matter of fact, the order books of the latter firm show sales for upwards of 17,000 H.P. of machinery during the period mentioned.

STOCK EXCHANGE NOTICES.—The 17th inst. has been appointed a special settling day for £150,000 3½ per cent. debenture stock of the *St. James' and Pall Mall Electric Light Co. (Ltd.)*, and the stock, together with £348,777 4 per cent. debenture stock of the *Western Telegraph Co. (Ltd.)* has been ordered to be quoted in the official list. The committee has also been asked to allow 10,000 ordinary £5 fully-paid shares (Nos. 1 to 10,000) of the *Folkestone Electricity Supply Co. (Ltd.)* to be quoted in the official list. This is a renewed application.

WESTERN UNION TELEGRAPH CO.—The total earnings for the year ended June 30 were $6,165,000 net, the gross increase being $804,258 and the net increase $296,631.

The Light Emitted by the Continuous-Current Arc. By Mrs. Ayrton. Illus. Concluded	966		

NOTES.

ON another page we give the conclusion of Mrs. AYRTON'S Paper on "The Light Emitted by the Continuous-Current Arc." The explanation arrived at, that the arc column selectively absorbs the more illuminating rays of the light from the crater seems unavoidable, and is one which will probably meet with ready acceptance by all who have studied the subject. To explain the increase of this absorption with increased arc length obviously requires either that the thickness of the absorbing medium, or that its absorbing power increases with increase of arc length. We hardly think there is yet sufficient reason to choose the latter explanation in preference to the former. Mrs. AYRTON considers that in long arcs there occurs a condensation of carbon vapour to mist, and that the solid particles of this mist selectively absorb the visually brighter rays while reflecting the violet. However, without going into the mechanism by which the absorption is effected, it would seem better—provisionally at all events—to explain the increased absorption merely by the probable increase in the thickness of the vapour through which the light from the crater has to pass in long arcs. M. BLONDEL'S measurements of the light radiation of the arc were, we believe, made with his lumenmeter, which measures the total flux in one operation. Polar diagrams of the light radiation with short and long arcs at constant current would probably be fruitful of indications as to the cause of the greater absorption of the light emitted with long arcs. It would be a laborious task to produce them, but perhaps Mrs. AYRTON, whose steady and patient research in this special subject has been already fruitful of such good results, will be tempted to conclude her present investigation in this manner.

IT will be remembered that when the City of London Electric Lighting Co. applied to the London County Council for sanction to an alteration in its standard supply voltage, under the Southwark Electric Lighting Order, from 100 volts to 200 volts, the Council only consented to this modification under conditions which were prohibitive to a dividend-earning company. After changing the wiring in consumers' premises at their own cost, the company were further to allow its consumers a reduction of 15 per cent. in the price charged for electrical energy; they were to undertake to impose no extra charge to consumers who objected to being changed-over to the higher pressure, and finally were to guarantee the house wiring for a year. The company wisely availed itself of its right to appeal to the Board of Trade against this action of the London County Council, and it will be seen in our report of the Council's proceedings in another column that only one of the London County Council's conditions has been allowed, viz., that justly specifying that the company should bear the cost of any necessary re-wiring of the premises of a changed-over consumer.

ANOTHER important matter which has been pending for some time is an appeal from the decision in the case of a police court prosecution brought by the London County Council against the London Electric Supply Corporation for not maintaining a constant supply of electrical energy. The summonses taken out against the company in May had been dismissed by the magistrate, but he had stated a case for a superior Court. On the assurance of the company that it was highly improbable any similar failure of supply would occur in the future, the Council has now decided to abandon further proceedings. On previous occasions the magistrates have always held that undertakers failing to supply were absolved from the penalties in the Board of Trade regulations if the failure had occurred through accident or unforeseen emergency, and it is probable that, if the Council had made the appeal, this view of the

Digitized by Google

matter would have been upheld. It would, however, have been advantageous to the electric supply industry to have obtained an opinion on the case in the Court of Appeal.

THE article on American cable manufacture, reprinted in another column of this issue, will be read with interest by both cable makers and cable users in this country. Of course, the general principles of cable manufacture must be the same all the world over, but on important points of detail it appears that American practice differs from British. For instance, if Mr. MAVER is correct in stating that conductors are not usually stranded unless of a greater diameter than a quarter of an inch, American users of cable must be satisfied with considerably less flexibility than is considered necessary in this country. The insulation of paper-covered conductors is now rendered more flexible than formerly by not laying on the strip so tightly, a necessity recognised, we believe, by British cable makers some years ago, but on the other hand, it would seem that the Americans have not yet imitated some manufacturers here in substituting layers of tape ("half lap") in the same direction for the "reverse lap" universally in vogue at one time. Seamless rubber insulation has also been tried and found wanting by our manufacturers, the reason assigned being usually that the modified sausage-machine employed for covering wire in this manner demands an inferior and more plastic india-rubber compound than that which can be laid on by the longitudinal, or by the taping process. Even with rubber cables of the latter class, deterioration has usually been traced to the properties of the material itself rather than to an opening of the seam.

WE publish this week a description of the most recent form which the POLLAK-VIRÁG system of high-speed telegraphy has taken. Our readers may remember that just over a year ago we published an account of this system as then developed, and gave some of the results which the inventors had obtained with their apparatus under favourable conditions. Speed of transmission up to 100,000 words per hour were obtained, while the average rate proved to be between 1,800 and 1,500 words per minute. By an ingenious addition to the original form of their apparatus the inventors have now made it capable of recording its messages in ordinary handwriting. In doing this, speed has been lost, but even yet a rate of transmission of about 1,000 words per minute is said to have been attained. This performance involves the writing of about 80 complete characters per second. The permanent recording of so great a number in so short a time has been rendered possible by the great advance made in recent years in the preparation of sensitive papers; indeed, the success on a practical scale of this new high-speed system depends largely on the reliability of that material. When employed on ordinary lines under the conditions of daily practice one may expect a considerable reduction in the speeds mentioned, but be that as it may, Messrs. POLLAK and VIRÁG are to be congratulated on a most important invention in the art of telegraphic signalling.

AFTER much discussion, in August last the Marylebone Vestry, anxious to emulate the example of the neighbouring parishes of Hampstead, Islington and St. Pancras, authorised a sub-committee to conclude negotiations with the Metropolitan Electric Supply Co. for the purchase of the portion of that company's undertaking within the parish of Marylebone, at an estimated cost of between £900,000 and £1,000,000. It appears from the report of the proceedings of the Vestry (reprinted in another part of this issue) that this resolution, although passed on August 2nd with only one dissentient, needed confirmation by a subsequent vote, and this vote, taken on Tuesday last, negatived the former resolution. The Marylebone Vestry will, therefore, not bequeath to the Borough Council succeeding it next month an electric light undertaking that had cost nearly a million pounds.

ELSEWHERE in this issue will be found an abstract of an important Paper by Dr. BARNES, of the McGill University. This Paper describes the methods and discusses the results of a long series of refined experiments undertaken primarily with the object of finding the value of the mechanical equivalent of heat in terms of the international electrical units. A new method of calorimetry was employed by Dr. BARNES—a method whose reliability seems adequately certified by the results of these exhaustive experiments, and bids fair to become a classical method for the calorimetry of liquids. GRIFFITHS, in his Paper on his determination of the mechanical equivalent (*Proc.* Roy. Soc., 1893) showed that the accuracy of modern electrical standards is comparable with the degree of accuracy to be hoped for in the determination of J; so that this connection between the electrical and the fundamental mechanical units might serve as a check on the more direct methods of establishing the values of electrical quantities in absolute units, if the direct mechanical methods of determining J involve errors of experiment not larger than those inevitable to the electrical methods. Since the epoch of ROWLAND'S masterly researches on the value of the mechanical equivalent the direct mechanical methods of determining J have attained a high degree of accuracy, and, in consequence, the determination of the value of J in electrical units may be made a step towards reducing those units to absolute measure.

DR. BARNES, in his Paper, takes, implicitly, this view of the case, for he uses the value of J found by the direct mechanical method by REYNOLDS and MOORBY to correct the value he had assumed for the E.M.F. of his Clark cells. The moral seems to be that when we are dealing with potential differences whose exact values we must know to within a small fraction of 1 per cent. we must not rely too confidently on even the most carefully constructed cell. This is not surprising; for, when we consider how in many other circumstances, and with regard to others of the electrical qualities of a substance, the minutest trace of impurity in the substance gives rise to comparatively large variations in the specific value of the electrical quality considered, the marvel is that the values of the E.M.F.s of different Clark cells agree so perfectly even as they are known to do.

Institution of Junior Engineers.—Sir Lowthian Bell, Bart. F.R.S., has been elected president of this Institution, in succession to the Hon. C. A. Parsons, F.R.S.

Electrical Engineers (R.E.) Volunteers.—Among the casualties at Vlakfontein on Oct. 10 we notice Lieut. J. H. Stubbs of the Electrical Engineers (R.E.) Volunteers, wounded.

University College, Liverpool.—A bequest of £1,000 has been made by Mr. Holbrook Gaskell towards the building and equipment of a new physics laboratory in connection with this institution.

Röntgen Society.—The first meeting after the recess will be held on Thursday, Nov. 1, at 20, Hanover-square, at 8 o'clock, when the President, Dr. J. B. Macintyre, will deliver his address.

Fuel for Gas Motors.—It should have been stated that the excellent translation of Prof. Witz's Paper on this subject, published in our last issue, was reprinted from our esteemed contemporary the *Journal of Gas Lighting*.

The Lighting of Ladysmith.—We referred to the fact, a month ago, that the Ladysmith Town Council was considering the question of the public lighting of the town. According to the *British and South African Export Gazette* the Council has now decided on electric light and is inviting tenders.

Cable Interruptions:—	Date of Interruption.
Latakia—Cyprus	June 21, 1899

Hackney Vestry Electric Supply Station.—The ceremony of laying the foundation stone of the Hackney Vestry electric supply station took place yesterday afternoon. The works, designed by the Vestry's consulting engineer, Mr. Robert Hammond, are to be on the three-wire system, with a declared pressure of 240 volts on each side. There will be four engines, two Willans and two Belliss, driving eight Lundell dynamos, with a total capacity of 1,800kw., the engines running non-condensing. A large proportion of the capital expenditure has been allocated to mains, which will include 36 miles of conductors. These will be B.I.W. lead-covered triple concentric cable laid "solid" in earthenware troughs.

Obituary.—We regret to announce the death of M. Adolph Cochery, one of the four honorary members of the Institution of Electrical Engineers. M. Cochery, who reached the advanced age of 88, was a member of the French Senate, and was at one time Minister of Posts and Telegraphs, having been industriously engaged in political work since 1848, when he was appointed principal private secretary to M. Crémieux, Minister of Justice at the time of the Revolution. He was also a conspicuous figure in the negotiations for the conclusion of the Peace of 1871. During his term of office he was responsible for many improvements in the French postal, telegraph, and telephone services. He was honorary member of the Instidtution of Electrical Engineers since 1881.——We regret to announce the sudden death on October 1st of Mr. J. E. Hudson, president of the American Bell Telephone Co. John Elbridge Hudson was born at Lynn, Mass., in 1839. He graduated at Harvard College, and in 1880 became general counsel to the American Bell Telephone Co. Five years later he was appointed general manager to the company, in 1887 he was made vice-president, and since 1889 he filled the position of president.

Telephony with Belgium.—An announcement has been made in the daily press purporting to have been inspired by the Assistant Engineer-in-Chief to the Post Office, to the effect that a telephone cable has been laid between England and Belgium, that it has been tested and found satisfactory, and that telephonic communication will shortly be opened between the two countries. We are authorised to state that there is no foundation whatever for this report. The question of telephonic communication between the two countries has, it is true, been discussed by the authorities, but nothing definite has been decided upon, although from a technical point of view there is very little doubt that successful telephony could be maintained across the North Sea. A telegraph cable of the ordinary four-core post office pattern was recently laid between Benacre (near Lowestoft) and Zandvoort (Holland), but it has not been proposed to use it for telephony, even if this would be feasible. It is not improbable that telephonic communication might be established shortly between England and Brussels, but if so, it will be viâ one of the Channel telephone cables—Calais and Lille.

Charing Cross and Hampstead Railway.—That much-talked-of scheme, the Charing Cross, Euston and Hampstead Electric Railway, has definitely been taken over by a syndicate of which Mr. Yerkes, the American financier, is the head. It is expected that work in connection with it will be started in February next, and that its construction will take at least two years. It is proposed to place the power station at Highgate-road, and to divide the northern part of the railway into two lines, one from High-street, Hampstead, to run down Haverstock Hill, and the other from a station adjoining the Midland Company's Kentish Town station. These two lines will unite at High-street, Camden Town, and run to Euston station, thence under Tottenham Court-road to a junction with the Central London Railway at Oxford-street, and from there across to Charing Cross. The Sprague multiple unit system will probably be employed, in which each car is a motor car, and the whole train can be controlled from the platform of any car. A 2½-minute service during part of the day and an all-night service are contemplated, and it is expected that the complete journey from Hampstead to Charing Cross will take only 20min.

The Metropolitan Electric Supply Co.—We learn that a large contract for motor-generators has just been placed with Messrs. Witting Bros. by the Metropolitan Electric Supply Co. As is generally known, the Metropolitan Company are gradually converting their old single-phase system into a continuous-current system, two-phase current being supplied from the new generating station at Willesden to the various sub-stations in the company's area, where at present it is merely distributed as alternating current after transformation to a lower pressure, but motor-generators producing continuous current are now to be added. The present contract is for the equipment of the new Manchester-square sub-station. It comprises six polyphase synchronous motor-generators of 500kw., each machine consisting of a 900 B.H.P. motor directly-coupled to a multipolar continuous-current generator of 500kw. In addition to the six large sets, there will be three auxiliary motor-generators of 70kw. to 80kw. for starting and exciting the large machines, and for helping with the day load. The two-phase current received from Willesden, at 10,000 volts per phase, is first transformed down to 1,000 volts per phase for the motor generators. The sub-station equipment will be of a highly interesting nature, as special arrangements are necessary in such cases to ensure the perfect parallel working of the large synchronous motors at all loads, the problem of feeding such large synchronous motors, placed at the end of a long transmission line, possessing both inductance and capacity, being by no means an easy one, when the power is supplied from a steam-driven station, as is the case in question. We are informed that Messrs. Witting Bros., who are the agents for the Charleroi firm, "Electricité et Hydraulique," have taken the present contract under heavy penalties and stringent guarantees.

The Tesla Patents.—A decision, considered to be of some importance on the other side of the Atlantic, has been given in the United States Circuit Court of Connecticut with regard to the three Tesla patents, Nos. 381,963, 382,280 and 382,279 of May 1, 1888. The following were the claims at issue in the three patents:—

Patent No. 381,968.

1. The combination, with a motor containing separate or independent circuits on the armature or field magnet, or both, of an alternating-current

Digitized by Google

generator containing induced circuits connected independently to corresponding circuits in the motor, whereby a rotation of the generator produces a progressive shifting of the poles of the motor, as herein described.

3. The combination, with a motor having an annular or ring-shaped field magnet and a cylindrical or equivalent armature, and independent coils on the field magnet or armature, or both, of an alternating-current generator having correspondingly independent coils, and circuits including the generator coils and corresponding motor coils in such manner that the rotation of the generator causes a progressive shifting of the poles of the motor in the manner set forth.

Patent No. 382,280.

The method herein described of electrically transmitting power, which consists in producing a continuously-progressive shifting of the polarities of either or both elements (the armature or field magnets or magnets) of a motor by developing alternating currents in independent circuits, including the magnetising coils of either or both elements, as herein set forth,

Patent No. 382,279.

1. The combination, with a motor containing independent inducing or energising circuits and closed induced circuits, of an alternating-current generator having induced or generating circuits corresponding to and connected with the energising circuits of the motor, as set forth.

2. An electro-magnetic motor having its field magnets wound with independent coils and its armature with independent closed coils, in combination with a source of alternating currents connected to the field coils, and capable of progressively shifting the poles of the field magnet, as set forth.

3. A motor constructed with an annular field magnet wound with independent coils and a cylindrical or disc armature wound with closed coils, in combination with a source of alternating currents connected with the field-magnet coils, and acting to progressively shift or rotate the poles of the field as herein set forth.

The action was brought by the Westinghouse Electric and Manufacturing Co., the owners of the Tesla patents, against the New England Granite Co., and the judge declared that the patents were valid, and had been infringed.

Effective Length of the Air-Gap with Toothed Armatures.—In the *Industrie Electrique* of September 10th M. C. F. Guilbert points out that the usual method of estimating the effective width of the air-gap in dynamos with toothed armatures is liable to error. Dynamo designers usually calculate the magnetic flux through the air-gap in machines with toothed armatures by taking the section of the air-gap as the mean between the total polar surface and the surface offered by the teeth; but this, M. Guilbert says, takes too low a value for the effective length of air-gap, which introduces an appreciable error when designing apparatus with unsaturated iron, such as alternating-current motors. By a simple application of the integral calculus, M. Guilbert arrives at the following more accurate expression for the reciprocal of the magnetic resistance of the air-gap:—

$$\frac{1}{R} = \frac{2L}{\log_e \frac{l}{l_1}} \log_e \left[\frac{l - l_1}{2\delta} + \sqrt{1 + \left(\frac{l - l_1}{2\delta}\right)^2} \right];$$

or for the effective length of the air-gap,

$$\delta' = \frac{l}{2} \frac{\log_e \frac{l}{l_1}}{\log_e \left[\frac{l - l_1}{2\delta} + \sqrt{1 + \left(\frac{l - l_1}{2\delta}\right)^2} \right]}.$$

In these formulæ, L is width of the machine, l_1 and l the widths of an armature tooth and the corresponding arc of the pole-piece, and δ the actual distance between the polar surface and the exterior of the armature core. For the case of machines in which both the polar surface and the armature are slotted the following formula is given:—

$$\delta' = \frac{l}{2} \frac{\log \frac{l}{l_1}}{\log \left[\frac{l - l_1}{\delta} + \sqrt{1 + \left(\frac{l' - l_1}{\delta}\right)^2} \right]} + \frac{l'}{2} \frac{\log \frac{l'}{l'_1}}{\log \left[\frac{l' - l_1'}{\delta} + \sqrt{1 + \left(\frac{l - l'_1}{\delta}\right)^2} \right]}.$$

l and l' are here the circumference of the armature divided by the number of teeth in the stator and rotor respectively, while l_1 and l'_1 are the actual widths of the teeth of the stator and rotor respectively.

Action of Sunlight on Lead Peroxide.—Herr Schoop has recently stated that electrolytic peroxide of lead is reduced by direct sunlight, and supported the assertion by the following experiment. He coated a sheet of soft lead with a paste made of peroxide of lead and sulphuric acid, left it to dry in the air, and then cut it into three portions, one of which he exposed to direct sunlight, another to diffused daylight, while the third was put in a dark place. After the lapse of some hours he found that the colour of the two samples exposed to light had altered considerably, the hue of that which had been exposed to direct sunlight having turned to a foxey red, and this change of colour Herr Schoop attributed to a change in the chemical composition of the lead peroxide. In the opinion of Dr. Peters, expressed in No. 16 of the *Centralblatt für Accumulatoren und Elementenkunde* this change of colour cannot be taken as a proof of change in chemical composition, for in the course of experiments on the formation of Planté plates he tested the correctness of Herr Schoop's assertion. Dr. Peters took two lead plates which had received an electrolytic coating of peroxide, washed them in running water whilst protecting them as far as possible from the action of light, and dried them in the dark. One of these plates, *a*, was left in the dark, whilst the other, *b*, was exposed for two to three days to daylight, 36 hours to 40 hours of which was direct sunlight. The hue of the plates became lighter, although not to the same degree as noticed by Herr Schoop, and this change of colour depends on the thickness of the peroxide layer, which was probably thinner in Herr Schoop's experiments than in those conducted by Dr. Peters. At the expiration of the time named the amount of lead peroxide on the plates was determined by a titration method, to be described later, and it was found from the result of several analyses of the two plates that plate *a* which had been kept in the dark contained a lower percentage of peroxide than plate *b* which had been exposed to the light, which seems to show that sunlight has no chemical action on lead peroxide, and that any lightening in hue of the peroxide plate which takes place is due to some physical cause, or to an alteration in the molecular groupings rather than to any change in chemical composition. With reference to these experiments on the effect of direct sunlight on lead peroxide, it will be remembered by many of our readers that Mr. R. E. Crompton in 1890 called attention to the fact that secondary batteries which were exposed to strong light had not the same capacity as those which were not thus exposed, and that those negative plates which were most exposed to sunlight or to the action of the arc light gave off hydrogen most rapidly, so that it would appear that light has some action on the electrolyte even if it does not affect electrolytic peroxide when dry.

MEETINGS OF SCIENTIFIC AND ENGINEERING SOCIETIES, &c.

(TO-DAY) FRIDAY, October 19th.

INSTITUTION OF MECHANICAL ENGINEERS.

8 p.m. First General Meeting of the Session. Paper to be read and discussed: "Observations on an Improved Glass Revealer for Studying Condensation in Steam Engine Cylinders, and Rendering the Effects Visible," by Bryan Donkin.

FRIDAY, October 26th.

PHYSICAL SOCIETY.

5 p.m. Meeting in the Rooms of the Chemical Society, Burlington House. Agenda: (1) "Exhibition of Experiments Illustrating Certain Phenomena of Vision," by Dr. Shelford Bidwell, F.R.S. (2) "On the Concentration at the Electrode in a Solution, with Special Reference to the Liberation of Hydrogen by the Electrolysis of a Mixture of Copper Sulphate and Sulphuric Acid," by Dr. J. S. Sand. (3) "Electromotive Force and Osmotic Pressure," by Dr. R. A. Lehfeldt.

INSTITUTION OF JUNIOR ENGINEERS.

8 p.m. Annual General Meeting at the Westminster Palace Hotel.

SATURDAY, October 27th.

INSTITUTION OF JUNIOR ENGINEERS.

3 p.m. Visit to the London Hydraulic Power Co.'s station, Millbank-street, Westminster.

THE NEW MUNICIPAL POWER STATIONS IN LIVERPOOL.

The Corporation of Liverpool decided in 1898, on the advice of Mr. A. Bromley Holmes, the city electrical engineer, to meet the rapidly-increasing demand for electrical energy for lighting and for tramways by the erection of two large power stations. The sites selected for these stations were properties owned by the Corporation, and situated at Pumpfields, in Vauxhall-road, and Lister Drive, in West Derby. They are about 2½ miles apart, and a line joining them passes approximately through the centre of Liverpool. The Pumpfields station is adjacent to the Leeds and Liverpool canal, which furnishes a supply of condensing water and facilities for the delivery of fuel, and the Lister Drive station has a siding from the London and North Western Railway. As there is no natural supply of water for condensing at the latter station, a cooling tower is in course of erection.

The two new stations, which are almost identical in size and equipment, are now complete. Mr. Holmes has been responsible for their design, while the buildings have been constructed from the designs of Mr. Thos. Shelmerdine, the Corporation surveyor, by Messrs. Morrison & Sons, contractors, Liverpool. The works are now in daily operation.

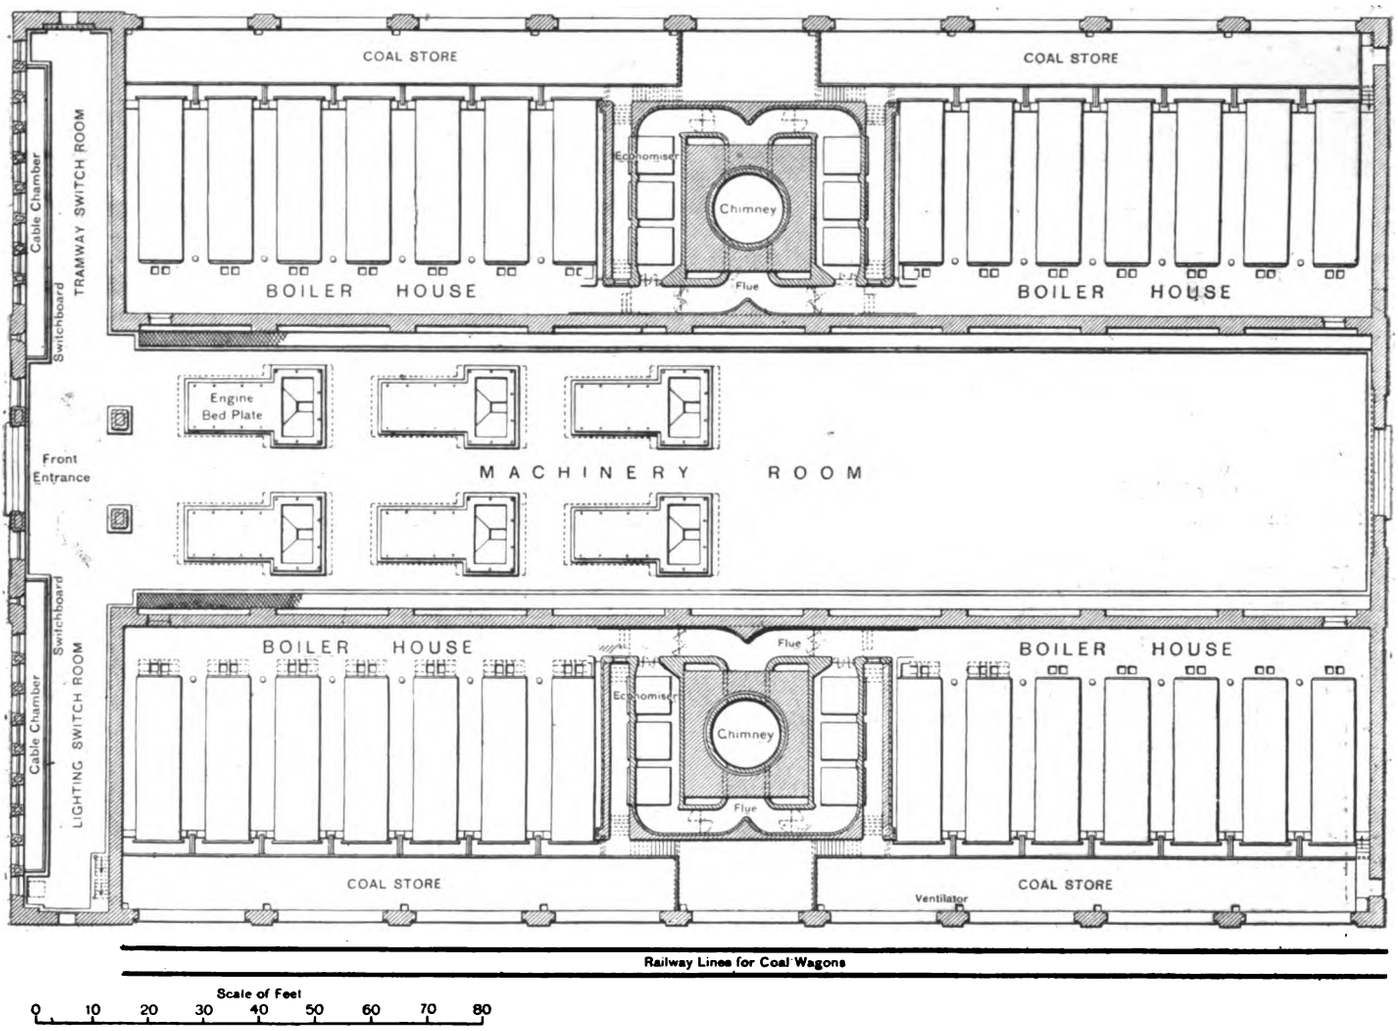
In each station the plant is divided into four independent sections consisting of seven boilers and economiser and three steam dynamos and accessories. The engine rooms are 247ft. long and 50ft. wide, with a boiler house 53ft. wide on each side.

We are indebted to Mr. A. Bromley Holmes, the city electrical engineer, for the greater part of the following description of the plant, and for the photographs from which our illustrations are made.

Pressure of Supply.—The distribution of electrical energy for the tramways is at 500 volts pressure with an earth return, and the distribution for lighting and power is on the three-wire system of 460 volts between the outer conductors, the middle wire being earthed at the station.

Engines.—Willans' single-acting, three-crank, triple-expansion, running at a speed of 230 revs. per min., with an output of 1,200 I.H.P. on continuous load and 1,500 I.H.P. for short periods. Main dimensions: Cylinder diameters 15in., 20½in., and 34⅝in.; stroke 16⅞in.; diameter of crank shaft 11in. The bearings are lined with white metal. The engines are fitted with a high-speed sensitive governor and speed regulating gear, and also with automatic expansion gear; the armature of the dynamo forms the flywheel.

Dynamos.—Siemens' multipolar machines with an output of 1,420 amperes at 550 volts. The field magnets are shunt-wound, and are mounted on a steel ring made in halves and strongly bolted together, carrying 10 inwardly-projecting steel poles. The armature winding consists of copper bars individually insulated and securely fixed in slots formed in the armature core, which is built up of a number of segments of sheet steel, supported on a cast-steel spider, and held together by bolts passing through steel end plates. It is provided with ventilating ducts. Each slot contains four



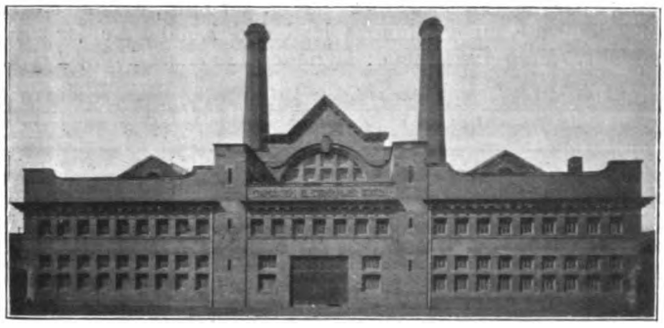
GROUND PLAN OF THE LIVERPOOL CORPORATION GENERATING STATION AT LISTER DRIVE.

Digitized by Google

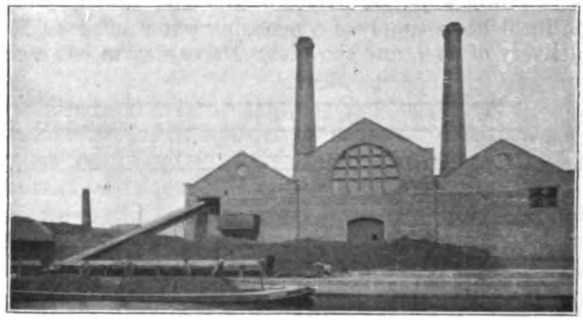
insulated solid bars of copper. The winding is of the drum type, and the bars are so connected as to form a multiple-circuit single-winding. The connections are arranged on what is known as the barrel system, which provides good mechanical support and at the same time reduces to a minimum the probability of breakdown of insulation.

The commutator is 57in. in diameter and consists of 560 segments of hard copper insulated by mica. It is so arranged as to permit of removal of sections without the necessity of taking the whole commutator to pieces, and is long enough to allow of axial adjustment of the brushes to equalise the wear.

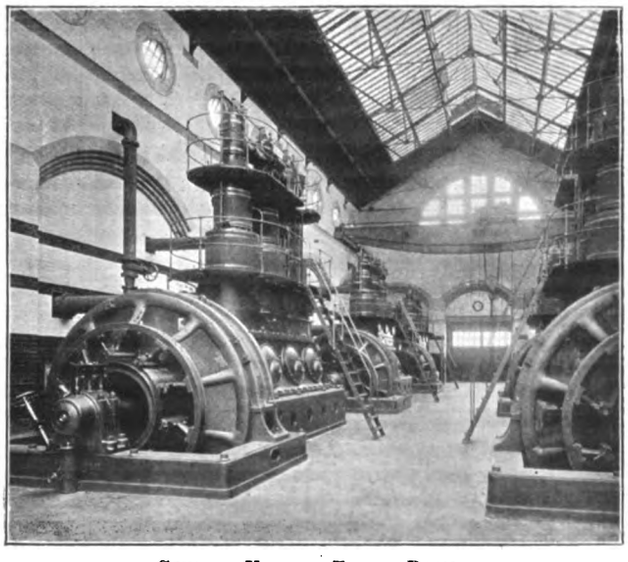
The brushes are of carbon. They are carried by spindles projecting from the rocking gear in the usual way, there being 16 brushes to each spindle. The brushes are carried by aluminium holders and held with a uniform pressure upon the commutator by means of steel springs. Flexible copper strips are used to form the connection between the brush holders and the gun-metal bar to which the cable connections are made. The spindles, referred to above, are fixed by insulated bolts to horizontal projections from a cast-iron ring forming part of the rocking gear, and this ring can be rotated for adjustment of the brushes in the usual manner by means of a worm wheel.



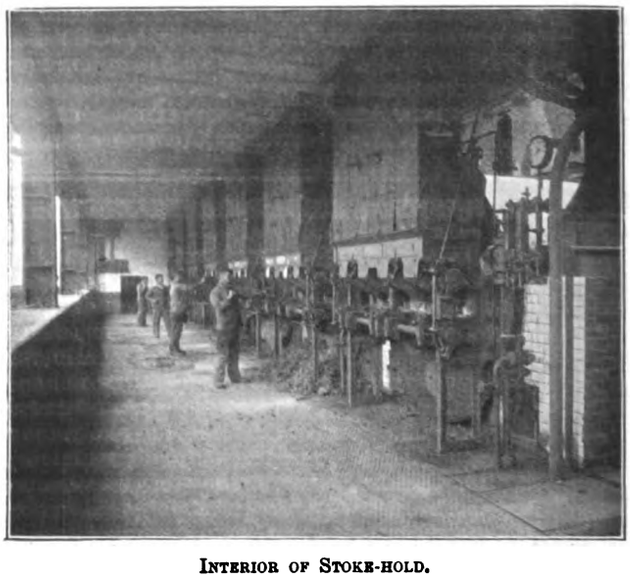
FRONT VIEW OF STATION.



BACK VIEW OF PUMPFIELDS STATION SHOWING COAL CONVEYER.



GENERAL VIEW OF ENGINE ROOM.



INTERIOR OF STOKE-HOLD.

Condensers.—At the Pumpfields station the condensers are of the Körting ejector pattern. There is a separate condenser for each engine, and they are supplied with water from an overhead tank, into which it is pumped from the canal adjoining the works. The condensers pass each 55,000 gals. of water per hour. The condensing water is raised from the canal by Allen's steam-driven centrifugal pumps to overhead tanks. Each pumping engine consists of a centrifugal pump coupled directly to a high-speed enclosed engine, each pump being capable of delivering 4,000 gallons of water per minute against a head of 50ft. The pumps are of the "Conqueror" centrifugal type having casings and discs of cast-iron. The suction and discharge branches are 16in. in diameter and the discs each 8ft. 6in. in diameter. Each pump is designed to pass the required quantity of water when running at a speed of 365 revolutions per minute. The engines are of the two-crank double-acting, high-speed enclosed compound type and are fitted with a system of forced lubrication. The cylinders are 11in. and 19in. diameter respectively, the stroke being 8in. in each case. The cranks are arranged opposite one another, and the oil is supplied to the working parts by means of a valveless oil pump from one of the eccentrics. These engines are of the same design as Messrs. Allen's standard two-crank electric lighting engines.

The water flows from the condensers, by gravity, in pipes along Vauxhall-road to a branch of the canal adjacent to Leeds-street, between which point and the station a large cooling area is provided.

At Lister Drive the condensing plant is being supplied by the Klein Engineering Co. It consists of a counter-current jet condenser and steam-driven air and circulating pumps, and the condensing water is cooled by means of two Klein chimney coolers. The condenser is fitted with an automatic exhaust relief and oil separator. The exhaust steam from each set of the three engines is carried in one main trunk to the condensing plant. The position of the oil separator is at a height which allows for the oil running out automatically by means of a barometric tube. This arrangement keeps the oily matter out of the condensing water and allows the latter to be used for boiler feed. The condensing vessel is fixed outside the engine house, and is so arranged that the steam is admitted at the end where the hot water is taken away, the air being drawn off at that end where the cold water enters, that being of course the coldest point. The air is taken away by means of a separate air pump coupled to a water circulating pump, which latter not only takes away the water from the condenser, but also lifts it to the cooler.

Digitized by Google

The pumps are of vertical type, and with compound steam cylinders, the air pump being on the Edwards principle. By this arrangement the ground space required is very little, the space occupied by them being about 14ft. by 9ft.

In the piping arrangement provision is made which renders it impossible for any condensing water to enter the steam cylinders of the main engines. The exhaust steam main trunk is carried to a height of some 34ft. above the injection water level before entering the condenser, and should any condensation occur in this piping before arriving at the barometric height provision is made for clearing it or drawing off such water through the air-pump. There is also provision made between the condenser and cooler for tapping the water (where its temperature is the highest) for feeding purposes. The coolers work entirely by natural draught, the draught being increased by means of a casing with which the cooling stacks are surrounded.

Boilers.—The boilers at Pumpfields have been supplied by Messrs. Tetlow Bros., and at Lister Drive, by Galloways Limited. They are of the Lancashire type, 30ft. long and 8ft. diameter; flues 3ft. 2in. diameter, each fitted with five Galloway tubes. Shell plates are of steel $\frac{7}{8}$in. thick. The circular seams are double-rivetted with lapped joints, and the longitudinal seams are butt jointed with straps inside and outside which are treble-rivetted. The flue plates are $\frac{1}{2}$in. thick. Each boiler is fitted with 8in. parallel slide steam stop valve, a safely valve for high steam and low water, and a duplex safety valve and the other usual fittings. Each boiler is also fitted with Vicars' mechanical stoker.

Economiser.—Each section of seven boilers is provided with a Green's economiser and vertical direct-acting steam feed pump in addition to the injector with which each boiler is fitted. The economisers in both of the works contain 720 pipes, arranged in six groups of 120 tubes each, the sections being ten pipes wide. They are constructed for 160lbs. pressure and fitted with patent internal lids. In each economiser there is a heating surface of about 7,200 sq. ft.

Coal Supply.—At Pumpfields the coal is delivered from a canal barge or from a cart on to a horizontal canvas belt conveyor, which delivers the fuel on to an inclined belt conveyor which elevates it into a large storage chamber situated over the mechanical stokers. An ample storage area for fuel is also provided on the space between the station and the canal. At Lister Drive a railway siding runs on each side of the station, from which the fuel is delivered into a wrought-iron storage chamber over the mechanical stokers.

Ashes.—The ashes are raised from the stokeholds by elevators on to a platform, from which they are delivered into the railway trucks or carts for removal.

Accumulators.—Each station is provided with an accumulator chamber, with accommodation for four batteries of 240 cells each, each battery being capable of giving a discharge of 200 amperes for one hour, or 80 amperes for four hours. The accumulators are used to equalise the load for the tramway service, and to assist in balancing the load on the two sides of the three-wire supply for the lighting service.

Switchboards.—At each station there are two switchboards, one for the lighting service and one for the tramways. The dynamos on one side of the station are connected to the tramway switchboard, and on the other side of the station to the lighting switchboard. The two switchboards are so connected that any set of plant may be used either for the lighting or for the tramway service. By this means it is possible to work the plant in the station in such a way that each set may run the same number of hours annually.

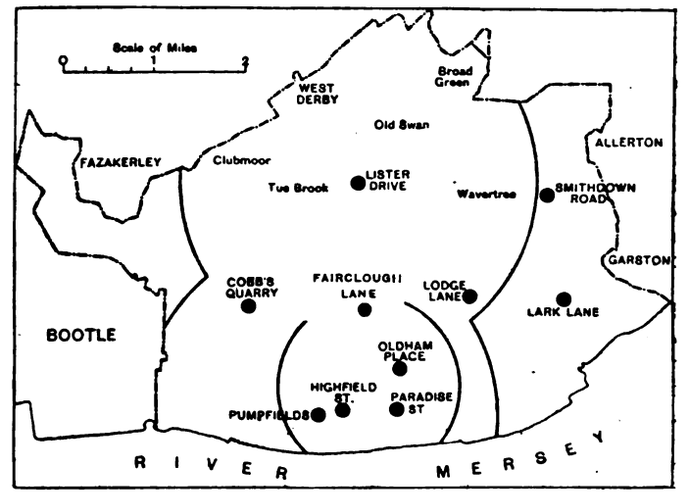
Balancers.—At each station balancers are provided for equalising the load on the three-wire mains, and motor generators are employed when charging the accumulators.

Motors.—The coal elevators, ashes elevators, mechanical stokers and economisers are driven by electric motors varying from 2 H.P. to 12 H.P.

At the present time there are the equivalent of 182,000 lamps of 16 c.p. connected to the supply mains of the Corporation, and more than 150 electric cars are in daily service on the tramways. The number of units supplied during the half-year ending June 30, 1900, was:—

For tramways	2,197,937
For lighting and power	2,243,225
Total	4,441,162

In addition to the two large stations described above, electrical energy is distributed in the central portion of the city from the Oldham-place, Highfield-street and Paradise-street stations, each having a capacity of about 3,000 H.P. Small supplementary plant is in operation at the Smithdown-road and Cobbs Quarry refuse destructors of the Corporation. Sub-stations for the distribution of electrical energy have been constructed at Fairclough-lane and Lodge-lane in connection with the new power stations. Finally, the residential district of Sefton Park and Princes Park derives its supply from the Lark-lane station, which with the three town stations referred to above were purchased by the Corporation from the Liverpool Electric Supply Co. (Ltd.) in the year 1893. Our map



SKETCH MAP OF LIVERPOOL, SHOWING POSITION OF STATIONS AND SUB-STATIONS.

shows the situation of the various stations and sub-stations. The dotted line indicates the city boundary, the two large circles are drawn at a radius of 2 miles from the Pumpfields and Lister Drive stations respectively, and the smaller circle (1 mile radius) indicates the central area of the city where the excess winter demand chiefly comes from.

ROCHDALE CORPORATION ELECTRICITY WORKS.

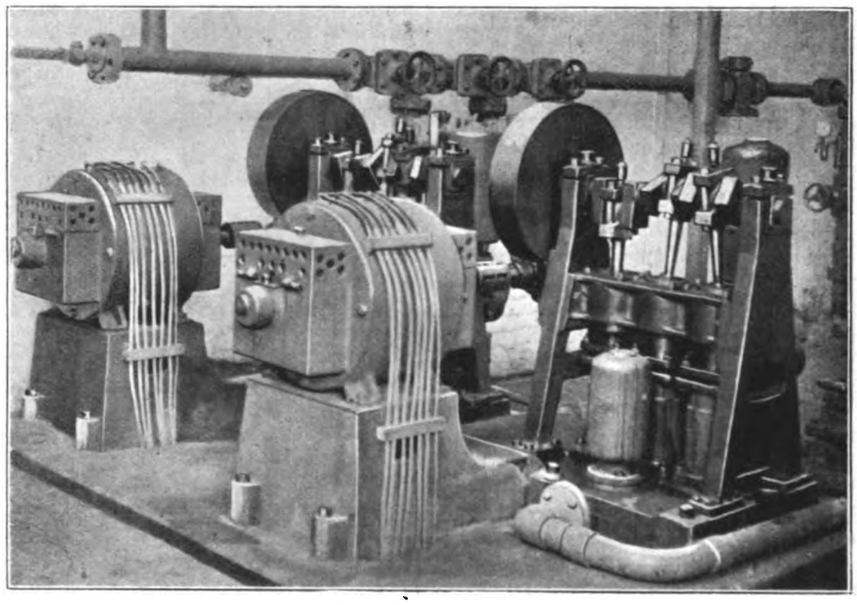
Although Rochdale is one of the most important towns in Lancashire, with a population of 75,000, the question of electric lighting did not assume practical importance until early in 1897, when it was referred to the Gas committee, under the chairmanship of Alderman Petrie. The committee immediately proceeded to visit various electricity works in the neighbourhood, and subsequently decided to appoint Mr. E. M. Lacey to advise, in conjunction with Mr. T. Banbury Ball, the gas engineer to the Corporation. The preliminary scheme was prepared and submitted to the committee in August, 1897, and this having received the approval of the Corporation, instructions were forthwith given to prepare the plans and specifications of buildings, plant, and mains. The necessary borrowing powers having been obtained, the contracts for the plant and buildings were placed as follows:—

Siemens Bros. & Co. (steam dynamos, balancers, &c.)	£4,640	0	0
Oldham Boiler Co. (boilers)	1,160	0	0
Green & Sons (economisers)	327	0	0
Mirrlees, Watson and Yaryan Co. (condensing plant)	885	0	0
E. Danks & Co. (pumps, feed, steam, and exhaust pipes, tanks, &c.)	1,440	0	0
Carrick and Ritchie (travelling crane)	198	0	0
Cowans Ltd. (switchboard)	848	0	0
Pritchett and Gold (accumulators)	1,152	0	0
W. T. Glover & Co. (cables)	4,978	16	10
Chamberlain and Hookham (meters)	463	15	0
W. A. Peters & Sons (buildings)	11,200	0	0
Total contracts	£27,292	11	10

Digitized by Google

The system adopted by the Corporation is a three-wire system with balancing machine and accumulators, the supply to consumers being at a pressure of 220 volts or 2 × 220 volts. A suitable site was found adjacent to the Corporation gas works, situated alongside a river from which water can be taken for condensing purposes. The buildings, which have been designed by Mr. T. Banbury Ball, comprise a handsome suite of offices facing Dane-street, engine house, boiler house and accumulator house and a chimney 150ft. high by 6ft. 6in. diameter.

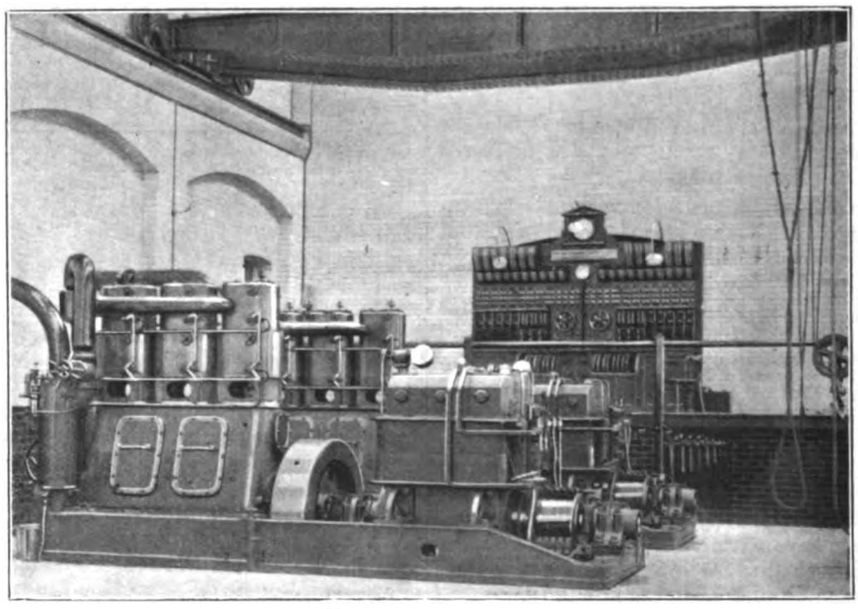
The boilers are of the Lancashire type, 30ft. in length and 8ft. in diameter, constructed for a working pressure of 150lb. Automatic stokers driven by a Lundell motor have been fitted to these. The boiler fittings are by Messrs. Hopkinson & Co. The economiser consists of 256 tubes. Its scrapers are driven by a Lundell motor, directly coupled through worm gearing to the scraper shaft.



Motor-Driven Pumps.

Messrs. F. Pearn & Co. are the makers of the feed pumps, which are of three-throw type geared to electric motors by means of worm-gearing working in an enclosed oil bath. Each pump is capable of delivering 2,000 gallons of water per hour against a steam pressure of 140lb. per square inch.

The motors are enclosed, each having two commutators for series parallel running, and were constructed by Messrs. Wilson Hartnell. The feed pipes are 3in. cast-iron, arranged to feed either through the economiser or direct to the boilers. The branch feed pipes to the boilers are in duplicate. A cast-iron tank, having a capacity of 3,000 gallons, has been provided for town water, and another cast-iron tank to hold 2,500 gallons for the hot-well.



View in Engine Room.

The steam pipes are of lapwelded steel, and the branch pipes to the engines of solid-drawn copper. All joints are made with corrugated brass rings. The steam pipes are lagged throughout with Leroy's lagging, and painted two coats. The exhaust pipes are of best quality cast-iron. Messrs. E. Danks & Co. were the contractors for the whole of the pipework, pumps, &c.

An electrically-driven surface condenser was supplied by Messrs. Mirrlees, Watson and Yaryan. This condenser is capable of dealing with 12,000lb. of steam per hour, and of maintaining a vacuum of at least 25in. on the exhaust pipes. On test a vacuum of 26in. was obtained. The air pumps are driven through spur gearing by an electric motor, constructed by Messrs. D. Bruce Peebles & Co. The circulating pump is driven directly by its motor, which is also of this firm's manufacture. Both motors are of the enclosed type.

The engine room has been provided with a 10-ton travelling crane by Messrs. Carrick & Ritchie. The span is approximately 33ft. and the lift 20ft.

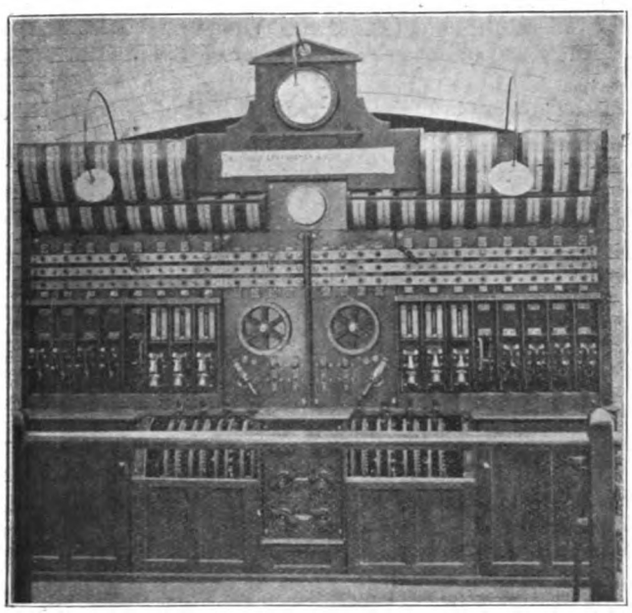
The generating plant consists of two three-crank Belliss tandem compound engines, self-lubricating, and arranged to work either condensing or non-condensing. Each of these engines is directly connected to a two-pole Siemens dynamo. These dynamos have each an output of 180 kw. as shunt machines, but a series coil has been added in order that the machines may be used either as simple shunt machines for the ordinary town supply or as compound machines for the tramway supply.

The switch-gear is of the edgewise type. It was constructed by Cowans Limited to the designs and specifications of the consulting engineers, Messrs. Lacey, Clirehugh and Sillar. The board is built up of strong black marble sections, and consists of accumulator, feeder, and dynamo panels, the feeder and dynamo panels being so constructed as to be interchangeable. All switch-gear and connections are on the face of the board, with the exception of the voltmeter wires, and all metal work has been so fixed that it may be removed, refixed, or replaced without the necessity of touching the back of the board. The board is provided with four dynamo panels and two booster panels, three omnibus bars and 24 vertical bars. The general design of the board is such that the switch gear and instruments of each dynamo or feeder are in one line of parts. The instruments were constructed by Messrs. James White. The overall dimension of the board is only 9ft. by 9ft. 6in. high.

The accumulators consist of 252 cells, capable of giving a discharge of 60 amperes for a period of 10 hours, or 250 amperes for a period of one hour. These cells have been supplied by Messrs. Pritchett & Gold.

Digitized by Google

Cables have been laid in all the principal streets. These cables are insulated with fibrous material substantially cased in lead, and the distributor cables are further protected by



SWITCHBOARD.

two laps of iron sheathing, and are laid directly in the ground. The contractors for the cable work were Messrs. W. T. Glover & Co.

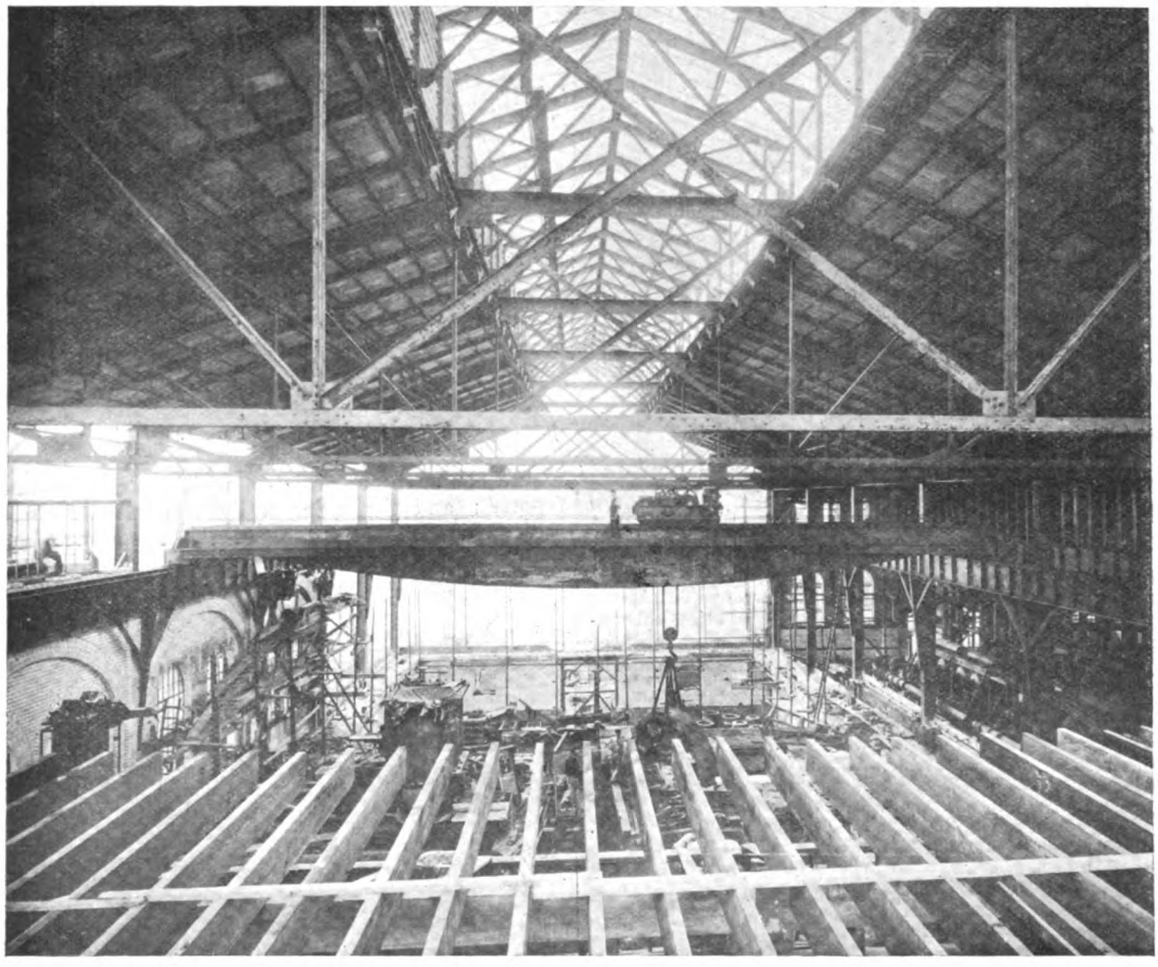
On the taking over of the works by the Corporation in September last, Mr. Atchison was appointed borough electrical engineer. Current is already being supplied in some parts of the town. During the last few months a fair number of applications for current have been received, and, having regard to the demand for traction which will arise on completion of the Corporation tramways, the committee will very soon find it necessary to take into consideration the question of extensions.

We are indebted to Messrs. Lacey, Clirehugh and Sillar for the above particulars, and for the photographs from which our illustrations have been made.

THE BRITISH THOMSON-HOUSTON CO.'S ELECTRIC CRANES.

The British Thomson-Houston Co. has just issued an interesting pamphlet on electrically-operated cranes. An illustration on the front page shows an artistic conception of "travelling cranes" flying rather low in the midst of typical Japanese flora. The apparatus described in the article, however, may be considered to be electrically driven without the assumption of Prof. J. C. Bose's electrical hypothesis of vital functions.

The company prefer three-motor cranes, one for each motion, and fit these with series-wound motors. As the speed of such a motor decreases in proportion to the increase of load, it is practically self-regulating, allowing the maximum load to be lifted at a definite speed, and all lighter loads at a proportionately greater speed. This has the further advantage that empty tackle can be lowered at a maximum speed which conduces to the efficiency and rapidity of the service. Shunt and compound-wound motors maintaining practically a constant speed at all loads are only employed for single motor equipments.



OVERHEAD TRAVELLING CRANE AT THE DUBLIN UNITED TRAMWAYS CO.'S POWER STATION.

Some time previous to the completion of the works, Mr. C. C. Atchison was appointed clerk of the works, and he has superintended the erection of the whole of the plant.

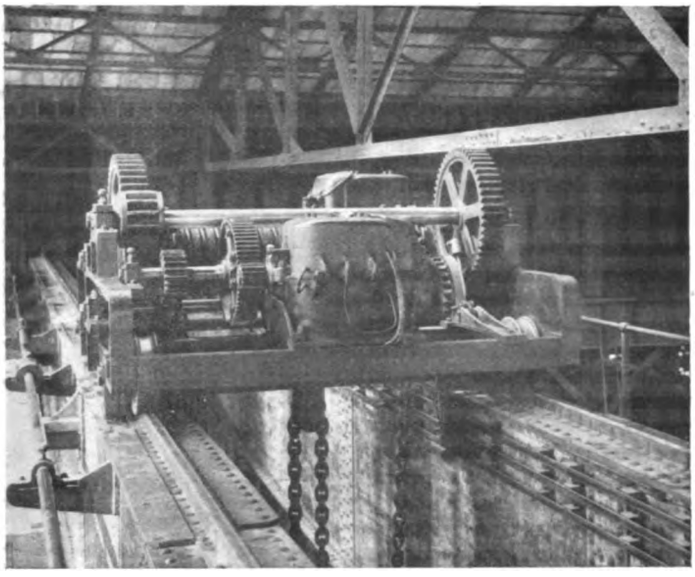
The type of enclosed motor chosen ("C.E." up to 5 B.H.P. and "G.E." for larger sizes) will stand an overload of 100 per cent. for a short time without injurious heating. The motors are rated on the

Digitized by Google

basis of the maximum horse-power developed continually for one hour, the temperature rise measured at any accessible part not to exceed 75°C. above the surrounding atmosphere.

Magnetic blow-out controllers are adopted, and for the smaller sizes, these have only one handle both for controlling the speed and reversing the motion. A practical modification sometimes employed consists of two of these controllers connected by means of a simple form of universal gearing which is operated by one lever. This is so contrived that any two motions of the crane can be controlled by means of this one lever, the arrangement being such that the movement of the lever indicates the direction in which the load is travelling. Thus one of these apparatus can be employed for the hoisting and traversing motor; when the lever is raised the load will be hoisted, and when it is moved over to the right or left the load will move to the right or left respectively, whereas if the lever be moved upwards in a diagonal direction the load will be both hoisted and traversed in the direction indicated by the lever.

An electromagnetic brake is operated by the hoisting motor and is so arranged that when the load is at rest and the controller is in the "off" position the brake is automatically applied, but as soon as the current is supplied to the motor the series electromagnet controlling the brake releases the latter. The current is conveyed to the motors on the crab by means of a number of bare copper wires stretched from end to end of the main girders, and generally attached to the inside of these. They are supported at either end by insulated turnbuckles which enable the wires to be strained up as required. The



Crab of Dublin Travelling Crane.

collectors attached to the crab consist each of a sliding contact formed by means of a copper hook which supports the wire, or else of a simple slide. Two bare copper wires stretched from end to end of the longitudinal travel convey current to the crane from the main source of supply. Attached to the main girders are two standard trolley wheels, so arranged as to raise the copper wire when passing under it, the weight of the wire itself facilitating good electrical contact. Our illustrations show the overhead travelling crane built for the new power station of the Dublin United Tramways Co. The following are its main dimension and data:—

Maximum length of longitudinal travel	141ft.
Span (centre to centre of gantry rails)	78ft.
Height of gantry rails from floor	27ft.
Bottom chord of roof principal to floor level	35ft.
Load, maximum	25 tons.
Speed, longitudinal traverse, fully loaded	not less than 60 per min.
Ditto, cross traverse, loaded	ditto ditto
Speed of hoist, fully loaded	4ft. per min.
Ditto loaded to 10cwt.	50ft. per min.
Height of lift (of load)	26ft.
Longitudinal distance between centres of stanchions supporting gantry rails	25ft.
Girder	6ft. deep at centre; 24in. at ends.
Crab rails	68lb. per yard.
Crab wheels—Cast iron traverse, 12in. diameter, chain barrel grooved.	
End carriage wheels, double flanged, 2ft. 6in. diameter; wheel base, 12ft.	
Voltage of motors	500
Type of motors	"G.E." 800 E.
Controller type R 13. Number	3 controllers.

THE POLLAK-VIRÁG WRITING TELEGRAPH.

In Vol. XLIII. of *The Electrician*, at p. 835, will be found a fairly full description of the Pollak-Virág system of high-speed telegraphy as perfected in the summer of 1899. Our readers

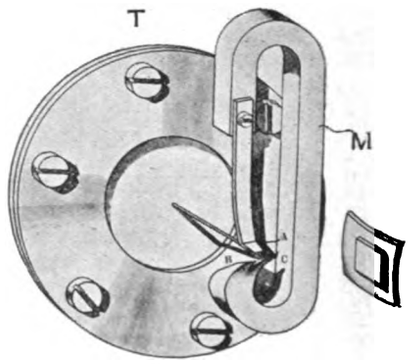


Fig. 1.

will remember that the receiver then described consisted of a telephone whose diaphragm was moved by impulses received from the line. To the diaphragm a rod was attached which

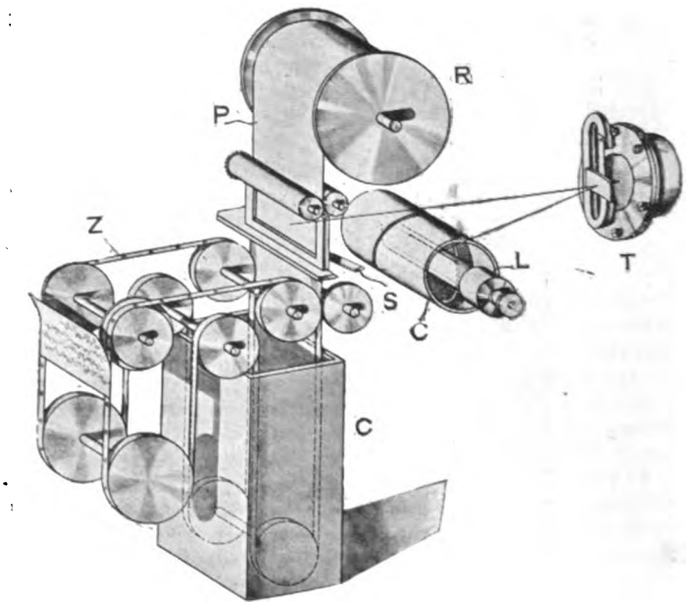

Fig. 2.

moved one of three points on which a small concave mirror reposed; and the beam of light reflected from the mirror registered the movements of the telephone diaphragm on

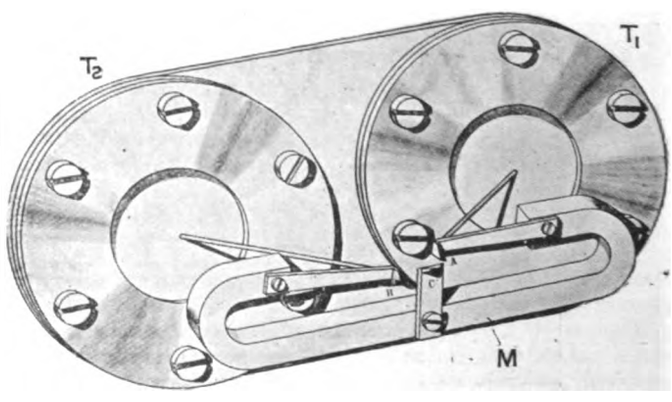

Fig. 3.

sensitised paper, which was moved forward uniformly on a drum. The small mirror was held in position on two pointed prongs of one pole of a stationary permanent magnet and one

Digitized by Google

movable prong constituting the other pole of the magnet by having cemented on its back a small piece of soft iron. It is to this movable prong that the rod from the telephone diaphragm was attached.

During the past year the inventors have greatly improved their apparatus. Fig. 1 shows the most recent type of diaphragm and mirror connection, while Fig. 2 gives a good idea of the arrangement of the parts of the complete receiving apparatus. By this apparatus messages are received and recorded in a zig-zag line as before; but now the record is traced in lines running from left to right of a broad strip of sensitised paper. This left-to-right movement is produced as follows:

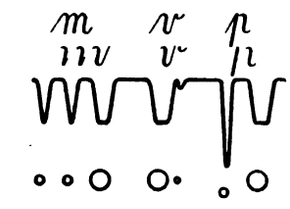

Fig. 4.

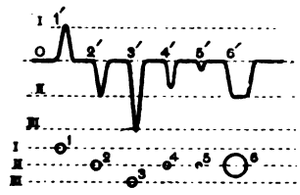

Fig. 5.

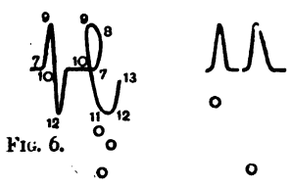

Fig. 6.

Fig. 7.

The source of light is a stationary glowing filament, which is surrounded by the cylindrical metal mantle L (Fig. 2). In this mantle a helical slit is cut, the helix having one complete turn. In consequence, when the mantle is appropriately turned about its axis, the source of the light falling on the mirror moves in effect uniformly from right to left, and hence the spot of light formed on the paper by reflection from the mirror moves uniformly from left to right. A series of motions of the mirror about a horizontal axis is recorded, therefore, on the paper as an up-and-down zig-zag line running from left to right, and commencing at the left end of a new line on the completion of every filled one. On the commencement of a despatch the revolution of the helically-slit mantle and of the sensitised paper feeder R is automatically started. At the close of the despatch the paper strip is cut, and the movement of the unexposed paper stopped, while the exposed strip is carried forward by clockwork into the developing bath C, then into a neighbouring fixing bath, and is finally pushed through a slot in the outer cover of the apparatus.

The apparatus in Fig. 1, however, yields only the zig-zag writing, of which a sample is given in Fig. 2 of our former article quoted above. For the recording of a message in the characters of ordinary handwriting, a double apparatus (Fig. 3) is necessary. This differs from the apparatus just described in having two telephones, and in having the concave mirror supported upon one fixed point and two movable points. One telephone moves the mirror about a horizontal axis, the other about a vertical axis, so that acting simultaneously the telephones can cause the reflected spot of light to trace any desired curve. A double-line wire is used. One telephone is, as before, in the loop of this wire; the other is between the loop and the earth. For producing the horizontal motion a positive current and a negative current of approximately equal voltages are required; for the vertical movements a positive current and an equal negative current and a positive current of double their voltage serve. Corresponding to these are obtained motions to left and to right, and up-and-down motions of equal amplitude, and a downward motion of double this amplitude. Fractions of this amplitude are obtained by shortening the duration of the contact at the sending end. This contact apparatus consists of a perforated paper strip, five slip rings connected to the batteries, and two brushes connected to the line. The size of the holes in the paper determines the duration of the contacts between the brushes and rings.

If the ordinary written Latin characters be dissected it will be found that certain of them, such as *m*, *v*, *p*, can be resolved into elements each consisting of a down and up stroke commencing and ending at the same height above the line. The letter *m* consists, for example, of three such elements, the letters *v* and *p* each of two. In order to cause the receiver to write letters which can be analysed in this way the currents sent from the sending end to produce vertical movements in the receiver are regulated with respect to direction, intensity, and duration. This is done by perforating the paper strip with larger or smaller holes in three rows I., II., III. (as in Fig. 5) corresponding to the three rings operated by one brush. A hole in row I. exposes to the brush the ring supplying a negative current of known voltage, in II. the ring supplying a positive current of equal voltage, in III. the ring supplying a positive current at double that tension. And the effect on the mirror of the receiver of holes punched as in Fig. 5 is shown above the plan of the perforations in the same diagram. It is a matter of trial to fix on that size of hole which allows just sufficient time for the current to exercise its full effect on the telephone. A larger hole then merely broadens the loop the spot of light traces on the moving sensitised paper in the receiver; while a smaller hole displaces the spot of light to a distance which is a fraction of the full amplitude. The perforations necessary to produce the elements of the letters *m*, *v*, *p* are shown in Fig. 4, where the elements are, moreover, so combined and spaced as to write the letters distinctly and in order.

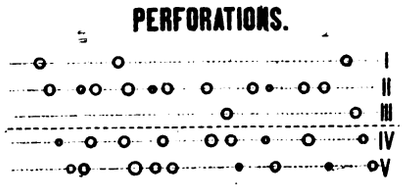

Fig. 8A.

Fig. 8B.

Fig. 8C.

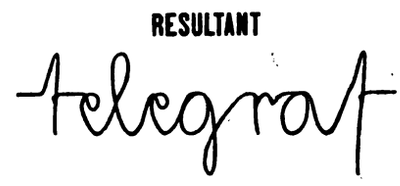

Fig. 8D.

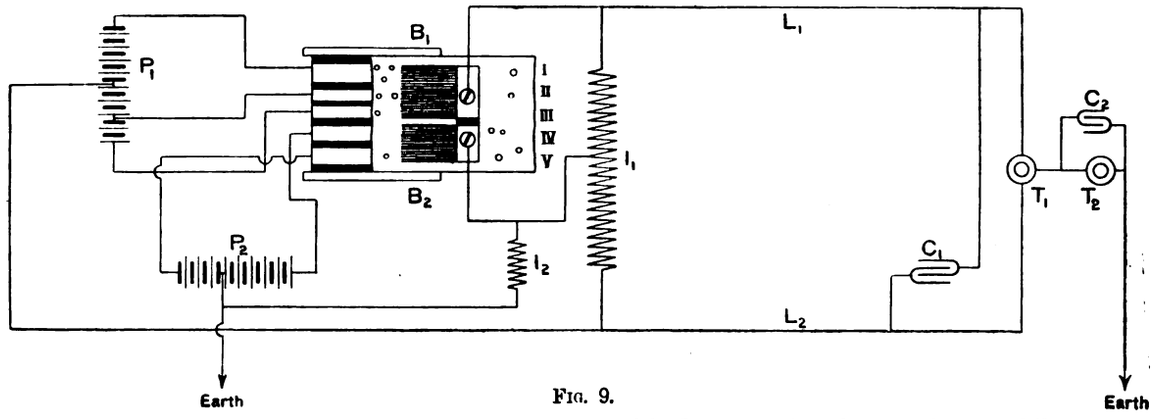

Fig. 9.

But the written Latin characters include many composed partly or wholly of closed curves, and these cannot be written by the mere up-and-down movements so far described; properly-timed to-and-fro horizontal motions are necessary in addition. Such letters are therefore resolved into and compounded from vertical and horizontal components. The movements of the

Digitized by Google

receiver mirror corresponding to each of these components are each produced by separate current impulses, and the time intervals between these impulses are chosen and obtained by deciding on the spaces to separate consecutive holes in the perforated tape. Take for example the letter *l*, which contains a closed curve or loop. Its vertical components merely, are written by the mirror as in the left-hand portion of the diagram in Fig. 6. This up-and-down zig-zag is the result of stimuli sent into the line through the perforations I., II. acting alone. The first hole, in row I., causes the curve 7, 9, 10 to be described on the moving paper; the second hole, in row II., produces the curve 10, 12, 13. But when a hole is, as shown in the figure, punched in the row IV. so that a current deflecting the spot of light from right to left is sent into the line, as soon as the spot of light in its upward motion due to hole I. reaches the place marked 8, a deviation to the left is produced—in spite of the forward march of the paper—which carries the spot of light to 9. Here the current through hole I. ceases, and the spot of light returns to 10, where it is immediately, in consequence of the coming of hole II., given a downward motion towards 11. Here the effect of hole IV. dies out, and the mirror, in restoring itself to its normal position, then writes on the moving paper the broad loop 11, 12, 13. Thus the second of the two telephones, by its production of horizontal to-and-fro motions of the mirror's normal, makes it possible to write letters containing closed curves.

In this manner any character of the alphabet can be written. The character must be analysed at the sending end into its horizontal and vertical components defined as above and compounded at the receiving end by the two telephones. The telephone T_1, Fig. 2, gives the spot of light the vertical motions dictated by holes in rows I., II., III.; the telephone T_2 the horizontal motions demanded by the holes in rows IV., V. The construction of the complete word "telegraf" on these principles is shown in Fig. 8. Fig. 8*a* gives a plan of the perforations in the sending strip; *b* gives the written record due to the telephone T_1 operated from the rows I., II., III.; *c* represents the effect on the telephone T_2 of the holes in rows IV., V.; and *d* is the resultant of the vertical and horizontal components.

The sources of current are two comparatively small batteries connected to the rings, line, and earth, as shown in Fig. 9. From the first battery P_1 are taken equal positive and negative currents corresponding to rows I. and II. of the perforated paper, and also a positive current of double the value corresponding to row III. From the second battery P_2 are taken a strong positive for the leftward deflection of the spot of light and a weak negative for the rightward deflection. It will be noticed from this diagram that, as before mentioned, only the telephone T_1 is included in the loop of the double line, the telephone T_2 receiving its impulses after they have passed as two oppositely-directed currents of equal strength through the telephone T_1.

The self-induction and the capacity of the wires and the effects of the natural oscillation-periods of the telephone diaphragms are compensated in a manner virtually identical with the method employed by Messrs. Pollák and Virág a year ago, and described in our article above cited. These compensating coils and condensers are diagrammatically positioned in Fig. 9, where I_1 and I_2 are inductance coils and C_1 and C_2 are condensers. By modifying the condenser C_2, moreover, the phase difference between the horizontal and vertical motions can be adjusted to a certain extent. As a final detail we ought to add that the perforating of the paper sending-strip is accomplished by a simple machine which punches simultaneously all the holes corresponding to any required character.

There is in this system of telegraphy no need for the syntonising of the sending and receiving apparatus, for variations in the speed at either end merely broaden or narrow the letters; and, therefore, the inventors claim that this system is simpler and more reliable considered merely from this point of view. Besides, with the aid of a distributor (such as Bandot's), about 30 sets of apparatus can work on one line.

At some recent trials, allowed by the Hungarian Minister of Commerce, a distance of 400km. (nearly 230 miles) from Budapest to Pozsony and back was spanned by two pairs of telephone wires, and most excellent results were obtained. The rate of transmission—at which rate very good writing was produced—reached 1,000 words per minute through a resistance of 2,000 ohms.

ELECTRICITY WORKS ACCOUNTS.

Hampstead Vestry Electric Supply Works.

In our first table this week we present an analysis of the last accounts of the Hampstead undertaking. These accounts indicate a maintenance of its past excellent progress. A study of the costs column will show that while all the several items of generating costs, except repairs and maintenance at the station, have increased, the reduction in this item to less than half its former value has resulted in materially lower total generating and works costs. The fuel item, even in view of the higher coal prices in force, seems still decidedly too high at 1·24d. per unit sold.

The management and property charges, already in 1898-9 presenting an excellent figure, was last year reduced to 0·42d. per unit.

Consequent upon the virtual reduction at the beginning of the year in the prices charged for supply by the change of the maximum demand limit of two hours to one hour, the average total receipts fell from 5·69d. to 5·18d., and the revenue for supply from 5·03d. to 4·69d. per unit. In spite of this material decrease, however, the working profit has only dropped from 11·5 per cent. on the capital to 11·8 per cent.

During the year the lamp connections were increased by 28·4 per cent., and the output by nearly 42 per cent. The load also was even more satisfactory in character last year than in 1898-9, the load factor having increased from 12·5 per cent. to 13·5 per cent., both high values.

The system of charge for the public arc lighting was altered from Lady Day, 1899. Formerly the charge was 6d. per unit with discounts, now the charge is fixed at £28 per annum per arc lamp, this charge representing the actual cost of supplying the current, together with renewals, &c. As the result of the new tariff is an actual decrease in the revenue from this source notwithstanding the increased number of arc lamps, there must have been a considerable profit made formerly.

The capital outlay per kilowatt installed shows a drop from £93 to £79, while the plant capacity has increased from 1,343kw. to 2,056kw. Since last year considerable station building extensions have been taking place. Four 500kw. alternators, two by Siemens and two by Ferranti, with Belliss engines, have been or are in process of being installed. Other plant is being installed, including a 50kw. exciter by Crompton, with Belliss engine, and six Davey-Paxman boilers (each to evaporate 10,000lb. water per hour).

To meet the outlay on these extensions the Vestry have applied for the necessary sanction to raise a loan of £97,178.

Guildford Electric Supply Co. (Ltd.)

By the substantial reduction which the directors of this little undertaking made in the tariff, they effected a most beneficial change in the rate of progress.

Although, naturally, the receipts per unit sold fell considerably, the output last year increased by no less than 101·5 per cent., while the lamp connections advanced during the year by over 56 per cent. In addition to this, the very low load-factor shows a satisfactory tendency to rise. In 1898 it was 5·84 per cent., last year it had risen to 7·62 per cent.

To these changes in the nature and extent of the business done is attributable, no doubt, the lower costs which are presented by the 1899 accounts. Even taking into account these better conditions, the works costs are all well under what might fairly have been expected of them. The management and property charges have also been very considerably reduced but still stand at a figure admitting, we are sure, of further reduction. That, notwithstanding the reduced receipts, the working profit in relation to the expended capital should have been increased is an excellent result.

The net profit was just sufficient to wipe out the preceding year's deficit of £223, so that the undertaking now makes a fresh start unhandicapped.

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878.

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny
Editorial Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co."

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"The Electrician" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	

New Volumes of "The Electrician" *commence in April and October.*

"The Electrician" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints" on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By E. Tremlett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d.; post free 13s. Vol. II. Price 12s. 6d.; post free, 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. New Edition. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. New Edition. 93 original illustrations, price 6s.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. New edition. Price 10s. 6d., post free; abroad 11s.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d. post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d.; post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d. post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gnipel and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free 2s. 2d. each; strong cloth 2s. 6d., post free 2s. 9d. each. Single Primers 2d., post free 2½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O. J. Lodge. New Edition. Price 5s. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, ELECTRIC TRACTION, TELEGRAPHS, TELEPHONES, &c. A. C. Curtis-Hayward, B.A. To January, 1900. Price 3s. 6d., post free.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work is in the press and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. Raphael. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

THE TELEPHONE.—By Dane Sinclair and F. C. Raphael.

SPECIAL NOTICE.

The present number of "THE ELECTRICIAN" completes Vol. XLV. With next week's number will be issued (Gratis) the Index to the Volume.

READY NEXT WEEK.—Vol. XLV. of "The Electrician." Price 17s. 6d. The volume will consist of 982 pages. Postage 1s. extra.

Cases for binding Vol. XLV. are now ready, price 2s.; post free, 2s. 3d.

UNDERGROUND SUBWAYS.

During the last few weeks the streets of the City of London have been in a state of disorder, rendering them in places almost impassable. The Post Office and the Charing Cross and Strand Electricity Supply Corporation are jointly responsible for this state of affairs, in their work of laying down cable for competing with the existing telephone and electric light services in the City. As this condition of the thoroughfares of our great metropolis will, in all probability, continue for some time, although work is going on in the principal thoroughfares both night and day, and as it discloses the multitude of pipes already laid under the streets for gas and water supply and hydraulic power, as well as electric light and telegraphy, the question is naturally revived in the minds of the general public: Would it not have been better to build a subway in which all these cables and pipes could be placed, and where they could be repaired, renewed, and extended without disturbing the surface of the roadway? As a matter of fact, short lengths of such subway already exist both in the City and in other parts of London. The City Corporation own about 2½ miles under various streets, and through these passages run a large number of pipes and conduits, including some belonging to the City of London Electric Lighting Co. and the Post Office, besides gas, water and hydraulic power mains. The London County Council are also the possessors of about an equal length of subway, and the Metropolitan and District Railway Companies have on some occasions permitted the use of their tunnels to the National Telephone Co. These few miles of subway are, however, practically unimportant in view of the large number of mains of various classes requiring periodical replacement and repair and the number of cables still to be laid in the metropolis for the extension of the electric light and the telephone services. The Corporation of the City of London, realising this rather late in the day, brought in a bill during the last parliamentary session, extending their powers with regard to the construction of such subways, and asking for powers to compel owners of mains to make use of these passages. This bill, with certain modifications at the instance of the Postmaster-General and others whose interests were affected, was duly passed and became law. It attracted little attention in Parliament at the time, probably because the clauses in question did not constitute the entire bill, although they formed the greater part of it. The bill was an "omnibus" bill of the usual kind; the important parts relating to "Public Service

Digitized by Google

Works" and "Structures over Streets and Public Lighting in Streets" being sandwiched in between a set of clauses providing for the construction of a crematorium at Ilford and a clause permitting the Corporation to enforce bye-laws for the proper maintenance of water-closets, privies, cesspools, &c. Both these are excellent objects, and from certain points of view may even rank equally with the question of subways for mains, but they were calculated to draw attention away from the part of the bill most liable to meet with opposition.

The act is being printed, and the Streets Committee is considering what action it shall take with reference to the proposed subways, so it will not be amiss at the present moment to examine more closely its scope. In the preamble, reference is made to the notice given by the POSTMASTER-GENERAL of his intention to break up all the principal thoroughfares in the City, as well as to applications by the National Telephone Co. for permission to lay wires underground, and to the fact that the Charing Cross and Strand Company had obtained a provisional order and would shortly require to open the streets also; but of course it was then too late to build a subway in time to render unnecessary this disturbance to traffic by two or three independent corporations. The first important provision in that part of the act itself which we are considering is that the City Corporation, as a preliminary to commencing the building of any such "public service works," is to deposit with the Board of Trade particulars and drawings of the subway it proposes to construct, and to send copies to the companies having pipes or wires in the streets in question or having the right to lay them there. Any of these companies can lodge an objection within 28 days, in which case the matter is to be submitted to an arbitrator appointed by the Board of Trade. Once such a subway is laid under a street, the Corporation will have far-reaching powers with respect to it. It will be entitled to compel the removal into the subway (at the Corporation's cost, however) of any pipes in the street; all new mains will have to be laid in the subway; and, moreover, any company desiring to interfere with the surface of the street in order to repair or renew a pipe other than a service pipe not in the subway must give the Corporation seven days' notice. As this latter provision would be a great hardship in the case of faults arising in electric light mains or telephone wires, there is a clause waiving it in case of emergency. Hitherto the Corporation have had certain compulsory powers with respect to the existing subways, but although they have been able to compel the laying of mains in the subways rather than in the street, they have had to give a free wayleave and charge no rent. In the new act, however, a clause is inserted entitling the Corporation to a rental. The rental to be charged is not specifically stated, but it is to be determined with regard to the saving to the company which is using the subway instead of having to break up the streets. This clause will, one would think, be fruitful of disputes. The Corporation will be empowered to make bye-laws with respect to the use of the subways and the work carried on there, but these bye-laws will have to receive the approval of the Board of Trade before being enforced.

We now come to the protecting clauses in the act. A 16-line paragraph without stops, and commencing with the words "Provided that," makes the Corporation responsible for any damage to a company by the removal of its wires into the subway, such as presumably might arise from the supply through a main being interrupted. Next, the emergency waiving clause already alluded to, and two clauses protecting the Metropolitan, Metropolitan District, and Great Eastern Railway Companies from interference. The City of London and the Charing Cross and Strand Electric Supply Companies have also secured the insertion of a provision excluding from the compulsory clauses of the act any of their mains laid in streets previous to the completion of the Corporation subways in those streets, the same applying to streets, notice to lay mains in which has been given previously to the construction of the subways. Finally, the POSTMASTER-GENERAL maintains the rights he has had hitherto under the Telegraph Acts of 1863 and 1899; he can make use of the subways or not as he likes, and if he has a wire in a subway he has the right to veto the placing therein subsequently of any other pipe or wire which he thinks would be injurious to his property there.

The remainder of this omnibus act is only of interest electrically by a clause empowering the Corporation to "affix to the external wall of any building fronting any street within the City any brackets wires pipes lamps and apparatus as may be necessary or convenient for the public lighting of the streets within the City"; providing, however, for compensation to any persons sustaining injury by this action.

It is open to question whether any substantial advantage would now be gained by the building of a regular network of subways such as the Corporation evidently contemplated when they drafted the present act. By the time such subways could be built, the two electric supply companies would have assured their position in the principal thoroughfares. Consequently the compulsory powers of the Corporation with respect to the subways would be confined to the renewal and repair of the gas, water, and hydraulic power mains, or the mains of any new company—such as the one proposing to lay on real sea-water in London. The electric lighting companies might find such subways convenient when they lay additional feeders to their existing mains, but they would not be compelled to employ them if they did not choose to. The same applies to the Post Office, which would also have a free hand. It is doubtful, however, whether these services would elect to have the gas and water mains as such close neighbours. A subway exclusively for electric mains would have been a boon if it had been available at the present crisis, but it is to be hoped, at any rate, that by the time such a subway could be finished the distributing networks in the central and most crowded parts of the City will be completed, and that nearly every office will have its telephone.

REVIEWS.

(Copies of any of the undermentioned works can be had from *The Electrician* office, post free, on receipt of published price.)

New London Boroughs: the Electors' Guide and Handbook. Edited by ROBERT DONALD. (London: Edward Lloyd, 1900.) 6d.

Public interest has been so absorbed with the General Election that another important election, which is pending, is liable to be almost forgotten. The citizens of the newly-formed London boroughs will have to elect their representative councillors on November 1. Mr. Donald's little handbook comes very opportunely therefore. It gives a list of the new boroughs and of the parishes constituting each of them, and this is embellished by sketch maps and enlivened with a recital of some of the characteristics of the various districts, and useful information as to their areas, rateable values, &c. This section of the book would be rendered still more useful, however, by an enumeration of the principal streets bounding the different boroughs. The remainder of the book contains the complete text of the London Government Act, 1899, with extracts from the other acts to which it refers, these extracts being necessary to understand fully its scope. We recommend this sixpenny volume to the large number of our readers who live, or have interests in, the great metropolis.

Preliminary Practical Magnetism and Electricity. By JOHN HENDERSON, D.Sc. (London: Longmans, Green & Co. 1900.) 1s.

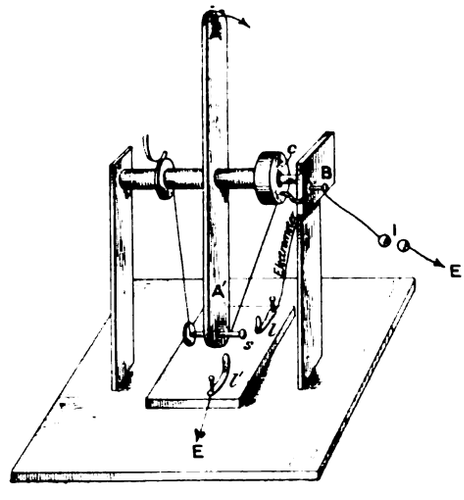
This little book is intended as a laboratory manual for beginners in electrical science, and contains a well-arranged series of elementary quantitative experiments needing for their execution but the simplest apparatus. For each experiment the necessary theoretical knowledge is briefly and lucidly outlined in a short "Preliminary," the apparatus distinctly specified, the operations to be performed by the student plainly indicated in order, and a table for the registration of data and results suggested. It is a book that will be appreciated by both students and teachers. Appendices, comprising hints on the conducting of the experiments, directions for the making of various simple pieces of apparatus, and a priced sketch of the complete equipment of a laboratory suitable for the course set forth in the book, add very greatly to the value of the little manual from a teacher's point of view.

We are, however, sorry to note in several of the paragraphs preliminary to an experiment rather serious misstatements quite unpardonable even in a very elementary text book. For instance, above Experiment No. 12 "On the Source of Energy in a Voltaic Cell," it is stated, in connection with thetheory of the simple voltaic cell, that "the difference between the amounts of energy in the zinc and the zinc sulphate [formed by the working of the cell] represents the energy expended [in heat] in the electrical circuit." Again, on page 20 it is stated that "it is only when the resistance of the external circuit is very large compared with that of the battery that adding cells will increase the current."

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. FOURNIER D'ALBE.]

Retardation of Discharge.—Jaumann was the first to show that a spark-gap is not always broken through by an appropriate difference of potential, but that sometimes several



seconds may elapse before the discharge passes. This retardation was studied by Warburg, and more recently by R. Swyngedauw. The latter first produces a gradual rise of potential by lowering the capacity of a condenser in the circuit. Having determined the potential at which the discharge sets in (the earth's potential being at one of the knobs), he next produces various abrupt potentials lasting for a small fraction of a second, and finds the higher potential now required for discharge. The difference between the two is then a measure of the retardation. The apparatus employed is shown in the diagram, where AA′ is a wooden lath driven by an electromotor at a known rate, I is the spark-gap, *c* a hollow metallic cylinder, *l* a tongue connecting with a Holtz machine, a condenser, and an electrometer, *l′* another connecting to earth, and *s* a metallic knob serving to alternately charge and discharge I through the brushes attached to B. The author finds that there is no retardation if the knobs are kept brightly polished. He also finds that ultra-violet light only lowers the discharge potential when it plays upon the knobs during the time they are being charged, but has no effect after the charging process is completed.

[R. SWYNGEDAUW, *Journ. de Physique*, September, 1900.]

New Telegraphone.—An improved telegraphone for demonstration purposes is described by E. Ruhmer. The steel band on which the records are made is wound on four rollers arranged in a rectangle, and the winding is so arranged that the band is continuous, and for a reproduction of the record it is not necessary to reverse the band and start it again, but simply to let it run on. The cores of both the recording and reproducing magnets are parallel to the breadth of the band, and not perpendicular to its surface. They are made to touch it. For the guidance of the wires, four brass combs are mounted near the rollers. The whole apparatus is driven by a $\frac{1}{16}$ H.P. electromotor, which imparts to the band a velocity of 3m. per second. The duration of speech is two minutes. That is not much for a phonograph, but, of course, it can be increased by increasing the number of rollers or the distance between them. Several hearing magnets can be arranged, and if it should be necessary to repeat a short passage that can be done by mounting a hearing magnet on another part of the wire, and switching it on as required. The author mentions a German sentence, giving the same words when reversed, which he has successfully reversed on this apparatus. It is: Ein Neger mit Gazelle zagt im Regen nie.

[E. RUHMER, *Physikal. Zeitschrift*, October 6, 1900.]

Terrestrial Magnetism in France.—Starting from Toulouse Observatory as a centre, E. Mathias has made a detailed survey of the distribution of the magnetic elements in the South of France, with special reference to the horizontal intensity, which shows a more regular gradation than the other elements. Instead of plotting the isodynamics on a map, he makes the difference in H a function of the latitude and longitude, thus

$$\Delta H = x(\Delta \text{ long.}) + y(\Delta \text{ lat.}),$$

and determines the coefficients x and y. The mean of 54 observations distributed over eight Départements surrounding Toulouse yields $-1{\cdot}26$ for x and $-7{\cdot}42$ for y, ΔH being expressed in units of the fifth decimal order and for the epoch 1896, and differences of latitude and longitude being expressed in minutes of arc. These values are not of merely local interest. By means of the coefficients, which are practically the same for the whole of France, and possibly for a larger area, the author has re-determined Moureaux's experimental values, and found his own values to agree with them within the errors of observation. Declination values treated similarly do not yield simple coefficients, as the declination, and the dip too, are affected by considerable irregularities, such as the maximum over Corsica.

[E. MATHIAS, *Comptes Rendus*, October 1, 1900.]

Platinum Thermometry.—An important piece of work has been carried out at the Kew Observatory in connection with platinum thermometers. C. Chree reports on a series of tests of six platinum thermometers by means of a Callendar-Griffiths resistance bridge. He enumerates no less than 18 sources of error which may affect the measurements, among them being thermo-electric currents, heating due to the battery current, error in the temperature coefficient, insufficient immersion, and slowness in acquiring the temperature to be measured. The effects of insufficient immersion are as dangerous in platinum thermometry as they are in mercury thermometry. Heat is conducted in from the outer air through the leads, or outwards in case of high temperatures. Unless the total immersion exceeds 10cm., the error is likely to exceed 0·01°C. The platinum thermometers tested were found to be four or five times slower in acquiring the temperatures to which they were exposed than mercury thermometers. An immersion of 3·5 minutes in ice and 2·5 minutes in steam suffices to bring the reading within 0·0005 of its stationary value. The author suggests a number of further experiments to determine the effect of long exposures to high

Digitized by Google

and to low temperatures, the variation of the boiling point o sulphur, and the behaviour of new platinum thermometers under a variety of conditions.

[C. CHREE, *Proc.* Roy. Soc., No. 435, October 3, 1900.]

High Resistances.—The usual method of measuring resistances, viz., that in which a current is sent through them and measured by a galvanometer, and in which the whole of the joulean waste takes place within the bad conductor itself, and not in the surrounding medium, fails when the resistance becomes about 10,000 megohms. It is just at that point that the "loss of charge method" begins to be useful. O. N. Rood is making an interesting series of experiments with the latter method, in which one of the ends of the bad conductor is attached to one coating of a charged condenser, and the other to a sensitive aluminium-leaf electroscope, which hands on to the earth any charge that succeeds in reaching it. The current observed has many striking analogies to a current of pitch. The latter takes some time to reach the end of its path, and if at any time a leak is made in the middle of the path, the pitch will flow into the hole from both sides. Such a phenomenon can be observed in a glass rod, connected as above described, when the electroscope connection is afterwards made in the middle of it. Electricity flows slowly from both ends into the new channel. In the case of ebonite, the electroscope end never attains the potential of the condenser end. It often acquires an opposite potential, probably due to some kind of induction.

[O. N. ROOD, *Am. J. Science*, October, 1900.]

Simple Relay for Space Telegraphy.—A simplified relay for use in Hertzian wave and coherer experiments has been devised by W. B. von Czudnochowski. Its general construction resembles that of an electric trembling bell. The axes of the electromagnets are horizontal, and the "trembler" hangs vertically down by their side. Its extreme point is provided with a platinum contact attached to a German-silver arm. The armature is rather heavy, and is weighted with an adjustable brass ball. It is covered with tissue paper next the magnet, and to avoid adhesion as far as possible the contact piece is so adjusted that it touches the insulated electrode before the armature touches the magnets. The armature is suspended by means of a thin German-silver spring, and its normal distance from the magnets is only 1mm. The whole apparatus is very cheap, and quite sensitive enough for most wave experiments. Thus the waves from a small Hertzian oscillator consisting of two straight cylinders 5cm. long and 1cm. in diameter can be detected over a length of 80 metres or 40 metres, and all the Hertzian reflection experiments can be made with it. It is even found that in the case of vertical propagation three ceilings, worked in stone and iron, when interposed in the path of the waves, do not sensibly affect the indications of the relay. Its sensitiveness can be readily adjusted.

[VON CZUDNOCHOWSKI, *Physikal. Zeitschrift*, October 6, 1900.)

ELECTRICITY SUPPLY FOR SMALL TOWNS.

BY C. S. VESEY BROWN, A.M.INST.C.E.
City Electrical Engineer, Lincoln.

Two Papers on this subject were read at the Huddersfield Convention of the Municipal Electrical Association, one of which was contributed by the writer of this article. Further prominence has lately been given to the question by the publication of the Board of Trade report on provisional orders granted in 1900. With the exception of those orders concerning London, practically the whole of the provisional orders obtained were for small provincial towns and districts, in some cases with as low a population as 3,500. In the Paper mentioned above the writer endeavoured to point out the absolute necessity of putting down machinery and cables which had stood the test of several years' experience, and above all to avoid anything in the nature of experimenting in any shape or form; to employ experts who were capable of saying yea or nay as to the qualities of the machinery offered; and that the surest way to success was to avoid anything which required a large annual cost in maintenance, or, in other words, to buy "standardised" machinery. Unfortunately, the ideas which prevail in England on local government do not tend to the erection of large power supply stations distributing over an area containing these smaller towns, such as would be and has been the practice on the Continent and in America, and therefore one is forced to the conclusion that at any rate for the next 10 or 20 years each small town will operate it own generating plant. It is to be hoped that the general principles which will actuate each of these towns will be the same, and that, at least, the systems of distribution will be so assimilated that in the event of the establishment of central power supply works, the connection of these distributing systems will not involve complicated and expensive means of regulation and transformation.

Reverting to the Board of Trade report, there are several interesting details given which show that this department of the Imperial Government is anxious to help forward the electrical industry. Inquiry into the finances of several local authorities has revealed the fact that the Board are not willing to grant statutory powers to local authorities who are unable to fulfil their obligations.

It would be interesting to know whether the Board of Trade and Local Government Board have sufficiently investigated the position of many other local authorities to see whether, before granting statutory powers for electric lighting, if the systems for drainage and disposal of sewage are adequate to the needs of the town or district; if sufficient has been done to properly metal and pave the roads and footpaths under the local authorities' jurisdiction; if efficient accommodation is made for infectious diseases beyond that provided by the poor-law authorities; or, again, is the water supply all that it should be, and many other points of far more importance to the welfare of the people than the question of being in possession of a monopoly for the supply of electricity.

If these matters had been properly investigated before provisional orders were granted, it is not unreasonable to suppose that the electrical industry would be in a more flourishing condition than it is now, and there would not be any excuse to offer or odious comparisons to make when comparing the electrical industry on the Continent with English progress.

It is perhaps too late now for an alteration in the law with respect to the granting of provisional orders, but the writer is firmly of opinion that if each town and district was originally made the owner of the right to supply electricity, and given, say, five years in which to make up its mind to supply under statutory powers, and if nothing was done to carry out these obligations to transfer the concession, either by auction or some equally convenient means, that there is not a town or district in this country which would not be operating an electricity works at the present day.

In the provisional orders granted in 1900 there is evidence that the local authorities who have consented to companies obtaining powers have in nearly every case made an agreement as to "terms of purchase" if it is thought desirable to take over the works before the 42 years specified in the 1888 Act. These terms of purchase vary from seven years, with 12 months' notice, to 14 years, with two years' notice. In some cases the premium on the capital is fixed, and in others the price to be paid by the local authority is specified as the "fair market value of the undertaking as a going concern."

As it is probable that similar bargains will be made in the ensuing and following sessions it will not be out of place to consider these terms with reference to the consumer, the local authority and the electrical industry. In all cases it is naturally felt that whatever premium on the capital outlay is paid it is somewhat in the nature of a reward for "pioneering" the undertaking against the competition of the gas works and to put the concern into such a state that there need be no fear that on the local authority taking over the works there will be no call on the local district rate to make up deficiency of income to pay interest and redemption of capital.

Digitized by Google

It is generally admitted that the capital cost of an electricity works is higher than for a gas works to supply the same area; the generating expenses of the two are about equal, probably less in the case of electricity where traction is supplied from the same plant; the distributing expenses are less in the case of electricity, but not sufficiently so to enable the electricity to return the same proportion of dividend that a gas undertaking is able to do, due no doubt to the residuals which are a well-known factor in gas manufacture. Following out this reasoning it is not unreasonable to suppose that, price being equal, the electricity undertaking will return say 6 per cent. where the gas undertaking returns 10 per cent. Probably 18 months will be lost in getting to work, and another 18 months in gaining sufficient clientèle to make the undertaking pay. The "fixed premium" investor, therefore, who undertakes to sell his works at the end of 8 years from the date of the order for the capital outlay plus 15 per cent., will have in five years to earn a dividend at the rate of between 9 per cent. and 9½ per cent. In other words, he will require to charge a relatively higher price than if his undertaking was carried on on the same lines as the "fair market value" investor, who hopes to obtain the corresponding amount of premium or reward by selling at such a price as will bring as many consumers into his net as possible, so that he may be able to argue before the arbitrator on the value of the undertaking that he has at least done his duty to the consumer by selling him electricity at as low a figure as is compatible with an annual return of, say, 6 per cent. on the capital invested for the time the works have been in operation. The local authority's position between the two is clear. If the "fixed premium" undertaking is bought it brings with it higher prices than a works bought on the "fair market value" price, and no sooner has it acquired the works than there is a general outcry to reduce the price and bring electricity within the reach of all, or, in other words, run the concern for the succeeding two or three years at a loss, and make up the deficiency from the rates.

The electrical industry in either case will be the better off, as will be quite understood, but it is hoped that in order to pay the relatively higher dividends on the "fixed premium" works there will be no inflating of capital due to the system of employing "middlemen" firms to supply the plant at wholesale prices, and allow the investor to charge list prices for his works, a difference amounting to as much as 20 per cent. in some cases. In this case the electrical industry would suffer by the probable decrease in the output of machinery.

The writer is quite of opinion that local authorities when making these bargains with companies willing to fulfil the obligations required by the Electric Lighting Acts should not fix a premium, but rather pay for the undertaking on the basis of the fair market value, or, in other words, payment by results, and his reasons for this conclusion are that if the company charge such a price for electricity as will not bring it within the reach of all, then their reward will be small and they have not "pioneered" the undertaking; on the other hand if the price is low enough to satisfy all classes of consumer, then there is no object in the local authority paying any premium so long as the undertaking is run on these lines and it is tacitly understood that the company are properly and efficiently carrying on their business in an equitable manner both for the investor and the consumer.

An "Economy Switch."—A correspondent has sent us an interesting circular from a German firm descriptive of an "economy switch." This contains a coil of bare wire serving as a rheostat, so that it can be employed as a "dimmer" in an ordinary lamp circuit. The following quotation from the circular speaks for itself:—

I also beg to point out that the original price is saved in current in a very short time. A 16 c.p. incandescent lamp uses as a rule 3d. worth of current in a night, whereas a 16-candle incandescent lamp used with an economy switch requires only ¾d. worth. The saving in current, then, for one night is 2¼d. The economy switch costs 12s. (*ex* my works here), and therefore the price is saved in current in 66 nights. You will further save during the first year: $360 - 66 \times 2\frac{1}{4} = ca.$ £2. 15s., and every year after $360 \times 2\frac{1}{4} = ca.$ £3. 7s. 6d. per annum.

Carrying this principle further by employing a lamp of sufficient size in the first instance, the consumer might save the entire cost of his installation within the year.

THE LIGHT EMITTED BY THE CONTINUOUS-CURRENT ARC.*

BY MRS. AYRTON.

(*Concluded from page 924.*)

It is hardly likely that rays of all colours should be absorbed with equal facility by the arc mist, and, indeed, there are certain indications that this is not so—that the absorption is distinctly *selective*.

Dr. Russell and Sir W. Abney have shown† that crater light very like sunlight, but has a slight excess of orange and green rays and a slight deficiency of blue. They measured the light in such direction that they were, as far as possible, getting rays from the crater *only*, that is to say, in a direction in which as few rays as possible from the arc itself reached the spectroscope. They were really, therefore, measuring the crater light as seen through a small quantity of arc mist, when they found it *yellower* than sunlight. But this very light, when it has penetrated through the mist of a long arc, is purple in colour, as may be deduced from the colour of the opalescent globes surrounding arc lamps when the arc is long. And this colour has nothing to do with the fact that our being accustomed to the yellow light of gas and incandescent lamps after dark makes a pure white light appear blue, for even in broad daylight the globes surrounding arc lamps in which the arc is long appear bright purple. Indeed, I have seen the inside of a screen surrounding a long arc, flooded with purple light as if lighted by a stained glass window, and retaining this colour *even when daylight was let in on it*. There can, therefore, be no doubt that the light of the crater becomes tinged with violet or purple as it passes through the arc, and that the tint deepens as the arc lengthens. If light became coloured in this way by being passed through coloured glass, we should say it was because the glass absorbed rays of certain colours and allowed other rays to pass. Why, then, should not this explanation apply to the arc mist?

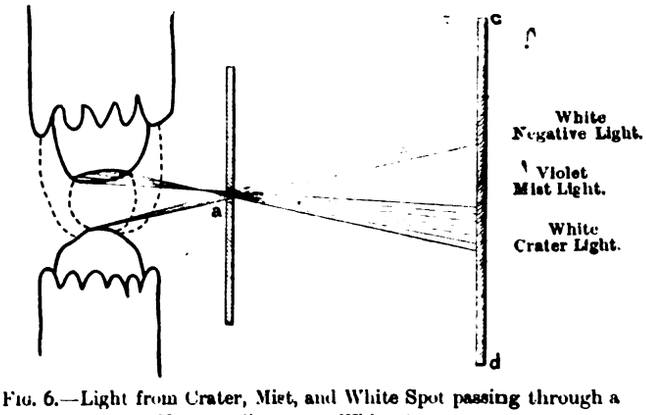


Fig. 6.—Light from Crater, Mist, and White Spot passing through a Narrow Slit on to a White Screen.

What probably happens is this. All the arc, except a thin layer quite close to the crater, consists of incandescent gases in which solid carbon particles are continually forming and falling. The vapour and gases must, of course, absorb a minute—probably an inappreciable—portion of the light that issues from the crater; were all, there would probably be no maximum of given length of arc; but the solid carbon particles in the mist have to be reckoned with. If the light were simply reflected from each of these that it encountered, and suffered only the small amount of absorption that would naturally take place, the whole quantity of light absorbed might still be too small to notice; but each ray may be reflected from particle to particle, and so the mist hundreds of times before it finally emerges. At each reflection part of the light that the particle is capable of absorbing is absorbed, and a ray that has suffered much internal reflection must emerge in a very different state from that in which it left the crater.

Suppose, now, that the carbon particles were absorbing the orange light and a certain amount of the green, but allowed all the violet light to pass. Then, after each reflection the light would become more and more violet, and that which had encountered many particles would be entirely violet. No incandescent gases give a dazzlingly brilliant light, so that when one looked at the arc mist alone, screening off the whole direct light from both carbons, the part of the crater light that was transmitted to the eye from the solid particles would entirely swamp the feeble

* Abstract of a Paper read before the International Electricity Congress at Paris.

† *Report* on the Action of Light on Water Colours, c. 5,453, 1888 pp. 23 and 69.

Digitized by Google

ight emitted by the gases, and one would only perceive a brilliant olet or purple light.

A very simple experiment will suffice to show that the light nitted by the arc *mist* is violet, while that emitted by the crater id the white hot spot on the negative carbon is white. If a thin etal plate containing a horizontal slit *a* (Fig. 6) about $\frac{1}{16}$in. in dth, be held vertically near an arc so that the slit is about equi-stant from the ends of the two carbons, and if the light from the rc that passes through the slit be received upon a vertical white reen *cd* (Fig. 6) a foot or two away, this light will form three rizontal bands on the screen, the upper and lower ones being white d the middle one of a bright violet. The slit is, of course, simply pinhole horizontally elongated, so that the upper white light must ceed from the negative carbon, as indicated by the lines in Fig. 6, lower from the crater, and the middle violet band must be lighted by the arc mist.

A still simpler experiment is that of shading the upper carbon, and part of the arc with any opaque body, one's hand, for instance. The shadow on the screen will then be found to be edged with a broad band of reddish violet light, this band being the portion of the screen that is illuminated by the mist, and the negative carbon alone (the red-hot part of this carbon gives the rosy tinge). Below the band is the part illuminated by all three sources—crater, mist, and white hot spot, and this naturally looks quite white when contrasted with the violet band. A diagrammatic illustration of this experiment is given in Fig. 7; *ab* is a metal plate, *cd* the white screen on which the light falls. The portion above is entirely in shadow, that between *c* and *d* is lighted by mist and negative carbon alone, and that below *d* is illuminated by the crater as well as by these.

We have, then, three facts to reconcile with one another.

1. The arc mist emits a violet light, while that of the crater and white spot is practically white.

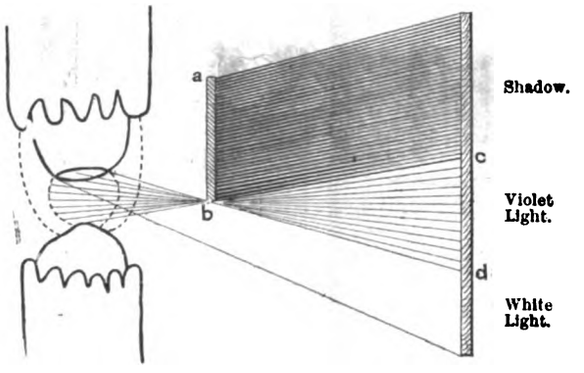

FIG. 7.—Band of Violet Light bordering the Shadow of a Metal Plate which is cutting off the Light from the Crater of an Arc.

2. The light of the whole arc, including all the sources in it, becomes more violet as the arc is lengthened.

3. The total amount of light received from all sources in the arc diminishes when the arc is lengthened beyond a certain point.

If it were not for the last fact, the first two might be accounted for on the supposition that the space between the carbons was filled with incandescent vapours and gases which emitted a violet light brilliant enough to give the white crater light a strong violet tinge. In this case, however, as the light from each of the sources in the arc [illegible] increase continuously as the arc is lengthened, condition [illegible] would not be accounted for, and consequently this explanation does not suffice. If, however, the violet tinge of the long arc is caused by the *absorption* of rays other than the violet rays, then all the facts are accounted for, and it is easy to see both why the light of the arc should be more violet as it is lengthened, and why also [illegible] quantity of light emitted should begin to diminish [illegible] arc was long enough for the increase in the amount of crater light that can get past the negative carbon to be more than counterbalanced by the increase in the quantity of that light that was absorbed by the mist.

Absorption [illegible]al reflection would also explain a curious anom[illegible]. Swinburne in the discussion on a very able Paper by Mr. Trotter* on the light of the arc. Mr. Trotter exhibited the curves [illegible] Abney which showed that crater light only differed from sunlight in having a slight excess of orange and green rays and a slight deficiency of blue rays. Mr. Swinburne pointed out that as crater light and sunlight were so very nearly of the same colour, the sun and the crater must also be nearly of the same temperature; but that, as the sun gave above ten times as much light per square millemetre as the crater, the emissivity of the sun must be ten times as great as that of the crater, which was incredible. This objection is perfectly valid if sunlight and the light *emitted* by the crater are really so nearly of the same colour. But Sir W. Abney was only able to measure the light *received* from the crater *after it had passed through a certain quantity of the mist*, for it is impossible for the crater light to get out without passing through *some* mist. Suppose, then, that the light *emitted* by the crater were very much yellower than the sun, but that even in passing through this small quantity of mist it was robbed of a considerable portion of its orange and green rays; then when it reached the photometer its colour would by this means have been brought much nearer to that of sunlight than it had been when it left the crater; it would have been rendered *bluer* in the course of transmission, and would appear therefore to have been emitted by a surface of much higher temperature than the surface of the crater actually is. Thus, if the mist does really absorb any considerable portion of the orange and green rays, Mr. Swinburne's objection no longer holds, for the crater light is probably far yellower when it is *emitted* than when it is *measured*.

* *Journal* of the Institution of Electrical Engineers, 1892, Vol. XXI., p. 381.

CABLE MANUFACTURE IN THE UNITED STATES.*

BY WM. MAVER, JUN.

The metal used for the conductors of underground electric cables is copper. Practically the only rival of copper for electrical purposes, outside of iron for overhead telegraph lines, is aluminium. This rivalry, however, extends only to overhead wires where the matter of diameter of the wire is not very material, the diameter of an aluminium wire being 1·27 times greater than that of a copper wire of equal conductivity. The weight of an aluminium wire, on the other hand, is one-half that of a copper wire of equal conductivity. At the present price of aluminium, which is slightly less than one-half that of copper, it would, therefore, be economical to use aluminium wire for overhead purposes, and this has been done recently in several instances. For underground purposes, however, it would seem that the greater diameter of the aluminium wire for a given conductivity must place it at a disadvantage, as compared with copper, on account of the greater amount of insulating material and lead required to cover the aluminium wire. The increased space that the latter wire would occupy in the underground ducts, where space is often quite a serious consideration, is also a disadvantage.

The process of manufacture of the cable may be taken up at the wire factory, where the copper is received in billets, or ingots, weighing about 200lb., which are first rolled into rods by rolling machines or mills. The ingots while red hot are passed through roll after roll, the rolls gradually reducing the wire to a desired size. In the first stages the rods are passed back and forth by men on each side of the mills, but as the rod increases in length and diminishes in diameter, it is passed from one set of rolls to another by curved guides. These rolls will break down 50 tons of copper per day of 10 hours from the ingot to a rod or wire equal to No. 5 B. & S. gauge (No. 7 B.W.G.). This process, however, does not leave the wire as uniformly round as desired; hence the rods are usually subjected to a "drawing" process, which consists in drawing the wire, while cold, by means of suitable machinery, through dies of hardened steel. It is usually necessary to repeat this drawing process several times with dies of gradually diminishing diameter, until the desired gauge of wire is finally reached. The drawing process hardens the wire and also materially increases its strength; at the same time it renders the wire less pliable. The strength of the copper wire thus hardened appears to rest very largely in a thin shell formed by the drawing process, for when the shell is nicked, even if only very slightly, the wire breaks readily at that point. Before each drawing the wire is covered with flour paste, baked on the wire in an oven. This acts as a lubricant while the wire is passing through the die. When the wire has been drawn to the desired size, it is annealed to the required degree of softness and pliability by heating, the extent of the annealing depending upon the use for which the wire is designed. For the conductors used for overhead telegraph and telephone purposes, it is not annealed after the final drawing, or but very slightly, and this wire is termed "hard-drawn." But for larger wires, such as No. 00 or No. 0000 B. & S. gauge (0·364in. and 0·460 in. diameter, respectively), the wire is always "soft-drawn." The wire used in cables is always soft-drawn, regardless of the size, to insure flexibility.

The wire being thus reduced to the desired diameter, the treatment which it will next undergo will depend on the nature of the insulating material with which it is to be covered. If a rubber compound is to be used, the wire will be tinned, it being supposed that this is a protection against any possible deleterious effects of the sulphur used in vulcanising the rubber. The tinning is effected by passing

* Abstract of an article on "Electric Cables for High-Tension Service, How they are Made and Tested in the United States," in *Cassier's Magazine*.

Digitized by Google

the wire through a vat of molten tin. When the insulating material is fibre or paper, the wire is not tinned.

The wire is now practically ready for use in the cable. There is, however, another matter to be considered first, that is, whether the conductor of the cable is to be "solid" or stranded. When the diameter of the conductor does not exceed 0·257in. diameter (No. 2 B. & S. gauge), the conductor is usually solid; that is, it consists of one wire. Above this size the conductor is stranded, chiefly to obtain greater flexibility of the cable.

The work of stranding the wire is usually done in one process. The wires of the strand are wound on reels, which are placed on suitable spindles, on frames around the stranding machine, the reels for each layer of wires being in the same circle. The circle of reels for each layer is, of course, placed a suitable distance behind or before its neighbouring circle, the reels for the larger layers being, naturally, behind those of the smaller. The centre wire of the strand passes from its reel, which is stationary in one place, and is held taut by a take-up drum or reel. The wires of the first layer are wound around this wire, and the wires of the second layer are wound snugly around the first layer, and so on, the reels of contiguous layers of wire being caused to revolve with their respective frames, in opposite directions, which gives the respective layers of the strand a right and left-hand lay. Machines for such work may be designed to carry 130 reels of wire, weighing 1,000lb. each.

As previously remarked, the insulating material of high-tension cables is now either a rubber compound or paper saturated with a resinous oil. Gutta-percha, which has been used so extensively—in fact, it may be said, exclusively up to this time—as the insulating material for long submarine cables, is not used at all for high or low tension cables in cities, its low melting point, about 120°F., being fatal to its employment for such purposes, inasmuch as this temperature is frequently encountered in city streets. Indeed, a temporary overload of a conductor might raise the temperature to this point, in which event the conductor would settle to the lead armour or sheathing of the cable, thereby, of course, ending its usefulness.

The pure rubber used in the rubber compounds employed as an insulating material is brought to the factory in balls, which weigh from 5lb. to 60lb. While this is termed "pure rubber," it is quite impure in a strict sense, and during the purifying process it undergoes a shrinkage of about 20 per cent. The first step in its preparation consists in soaking for about 12 hours in water at a temperature of about 200°F. or 212°F. After undergoing this boiling process the ball is passed through corrugated rolls or mills, by which the rubber is pressed into a thin rough sheet about the size of a sheep's hide. As the rubber is thus passed and repassed through this mill streams of water are caused to fall upon it, washing away the impurities which the roller exposes. After the sheets have been thoroughly washed they are taken to a drying room, where they are usually kept for two, three, or more weeks. The sheets are then taken to the "break-down" mills, where they are passed repeatedly through rollers which are kept at a temperature of about 200°F. This reduces the sheet to a homogeneous, plastic mass of pure rubber. The rubber is then folded into thick sheets and passed into the mixing room. Here, as the pure rubber is passed time after time between the rolls, the attendants add the ingredients, which make the completed compound, in such proportions as may be deemed advisable for any particular case, the proportion of such added ingredients, or adulterants, and pure rubber varying with every manufacturer.

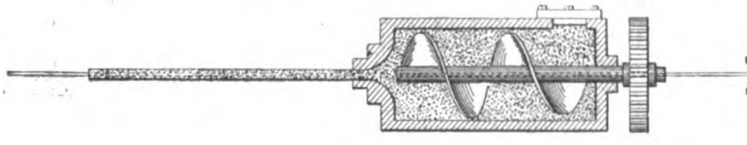

Fig. 1.—Diagram Illustrating the Operation of an Insulating Machine.

The ingredients composing a well-known rubber compound are as follows: 15lb. Para rubber, 4·5lb. litharge, 6lb. whiting, 4·5lb. blue lead, 7oz. sulphur. The amount of pure rubber used in the better classes of cable varies from 35 per cent. to 50 per cent. The various ingredients are added gradually to the rubber during the process of mixing, which requires for its proper operation a high grade of shop skill. The mills are kept at a temperature of about 200°F. during the process. In the mixing room of one large manufacturing company 6,000lb. of the insulating compound are prepared in a day of 10 hours.

When thoroughly mixed, the rubber compound is ready for placing over the wire. This is done in two general ways, first, by the use of insulating machines somewhat similar to the machines used in making rubber tubing. In the second method the compound is formed into a strip which is placed over the conductor. In the latter process the wire is rolled off a drum or reel, and passes through a guide to and between a pair of grooved wheels, where the rubber strip is lapped closely around the wire, the pressure causing the edges of the strips to adhere, and at the same time the surplus rubber is removed by suitable cutting edges on the grooved wheels. This produces a seam in the insulation.

The principle of the insulating machines used in the first-named method is shown in Fig. 1. Here the prepared compound is fed by an attendant into an opening in the machine; a worm draws the compound towards the die through which the wire is passing, and the wire is covered with the compound to the thickness desired, this being regulated by the excess of diameter of the die over the diameter of the wire. The compound is maintained in the desired plastic condition while in the machine by suitably arranged water jackets, the temperature of which is governed by valves which admit steam or cold water. The rate at which the wire may be covered in this way depends largely on the size of the wire and the thickness of the covering, which is termed the "wall." This method produces what is termed a "seamless" insulation. The wire, while being drawn through the die, is held by guides directly in the centre of the die to ensure an equal distribution or centering of the compound over the surface of the wire. The conductor, after issuing, covered, from the insulating machine, is drawn along a table through powdered talc, a distance of 40ft. or 50ft., to a drum, upon which it is carefully coiled. The wire thus covered may then be taped prior to vulcanising, or it may be vulcanised without taping, but in the largest sizes of cables it is customary to first tape the insulated wire.

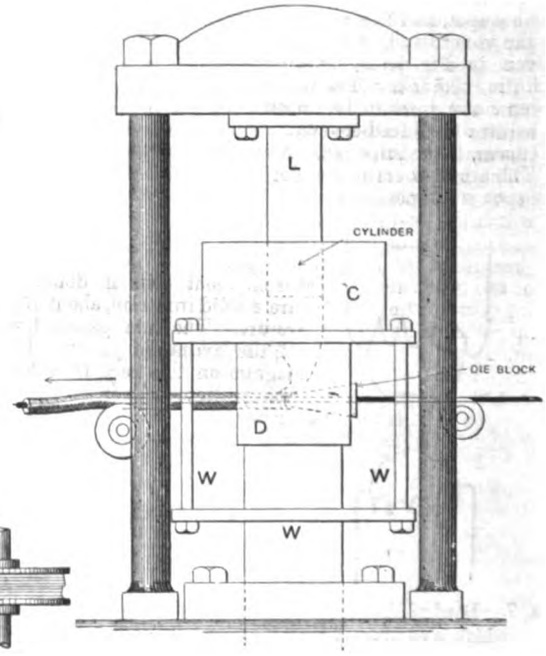

Fig. 2.—Elevation of a Lead Press.

The taping apparatus consists of a revolving disc on the face of which a reel holding the tape is suitably supported. The insulated wire or cable passes through a sleeve in the centre of the disc, and as it does, the reel, in the act of revolving with the disc, wraps the tape spirally around the cable. The latter passes from the iron take-up drum, to a reel, and is then ready for vulcanising. The process of vulcanising the compound consists in placing the wire and reel in an oven, where it is subjected to a steam or dry heat at a temperature of 250°F. to 300°F. Steam heat is preferred by many manufacturers as giving the best results. Much care is required in the process, and the most favourable temperature and the length of time required to bring the compound to the desired degree of hardness and tenacity are matters of experiment. They vary with different compounds.

At this point the manufacture of paper-covered cables may be considered. This consists essentially of winding strips of manila paper in reversed layers to any desired thickness over the conductor. When the conductor is covered it is wound on a suitable reel which, with the conductor, is placed in a "bake" oven, where it is subjected for hours to a temperature sufficiently high to drive all the atmospheric moisture out of the paper. The oven in which this baking is done is tightly sealed, except at a vent at the top. An attendant, by holding his hand above this orifice, is able to tell when the drying has proceeded sufficiently far by the nature of the air which passes out. After proper drying, the reel and conductor are immersed in a vat of boiling resin oil, often termed London oil, and as the baking process has rendered the paper exceedingly hygroscopic, it absorbs the oil with avidity.

Formerly the paper was placed over the wire as tightly as possible, but this plan has been abandoned for several reasons, one of them being that it imparted too great rigidity to the completed cable, with the result that the cable could not be bent without breaking the

Digitized by Google

insulation. Further, it retarded the heat in the bake oven from reaching into the inner layers of the paper to such an extent that the outer layers were injured by too long exposure to the heat of the oven. Again, when the paper was put on under strong pressure, the compound could not readily penetrate to the inner coils, and as the ability of such cables to resist high electrical pressure is largely due to the presence of the oil, the importance of this latter point is obvious. By placing the paper layers more loosely over the conductor the layers slip easily over one another when the cable is bent, and the heat and the oil more readily penetrate to the inner layers, thereby improving the insulation resistance and increasing the pressure-resisting quality of the covering.

The conductors thus insulated are now ready for bunching into cable form. For the high-tension cables here particularly referred to three insulated conductors are usually employed. These are laid up in a strand, or spirally, and are taped, the interstices being filled in with jute, after which the conductors are ready for lead-covering. In other instances the conductors are bunched, and a "jacket" of paper strips or rubber compound, as the case may be, is put around the conductors thus bunched. This latter method is sometimes termed "split" insulation, because of the fact that the insulation is divided between the jacket and the insulation over each conductor.

All cables intended for use in underground conduits in cities are now lead-covered to protect the insulating material from destruction by the acids, alkalies, &c., found in such conduits. In the case of paper or fibre cables it is absolutely necessary that they be covered with lead to protect them from moisture in the underground conduits. Rubber cables are, of course, moisture-proof, and if nothing but water were to be encountered in the conduits they would not require to be lead-covered. Rubber immersed in salt or fresh water appears to be imperishable, barring mechanical injury.

The lead-covering of the cable is an interesting process. Fig. 2 shows the appearance of a vertical type of lead-covering machine, in which the lead is put on hot. The framework and the other parts of this machine are of massive construction to withstand the heavy pressure which is applied in putting on the lead casing. The pillars of the frame are of solid iron, about 10in. in diameter. The working parts of the machine are a solid iron ram, about 15in. in diameter, operated by hydraulic pressure. The ram passes down several feet into a vault in the ground, the hydraulic pressure being applied at the lower end. In the diagram on this page D is the die block, C a hollow cylinder into which molten lead is poured; L is the lead ram, or plunger, of solid iron, 5in. in diameter, rigidly bolted to the framework. Its lower end fits snugly into the receptacle in the cylinder C, as indicated by the dotted lines. As the die block must be changed to suit the size of cable to be lead-covered, the frame WWW is provided to permit of its easy removal. There is a curved opening in the die block, which reaches to the guide through which the cable is seen to pass. The die block rests on the top of the lower ram, and the cylinder C rests on D, in which respective positions they are held by bolts.

In preparing the lead and machine for the operation of lead-covering the insulation, the operation is practically as follows: The hydraulic ram is dropped down, and carries the die block and cylinder with it, withdrawing the cylinder from the lead plunger L, which is stationary. The cylinder is then filled with molten lead, which is termed a "charge." As it is not desirable to place the lead in a melted state over the insulation, the charge is allowed to chill somewhat before the operation of covering is begun. The time for this varies with the size of the cable, and may be from 3 minutes to 4 minutes. To prevent undue chilling of the lead, gas jets are placed around the cylinder. At the proper time hydraulic pressure is slowly applied to the ram. The pressure exerted on the end of this ram, which, in some cases, amounts to 500 tons, causes the cylinder to rise up against the plunger, with the result that the lead is pressed down into the die, forming a tube or casing around the insulated conductor. At the same time, by suitable take-up reels, the cable is drawn through the die block. In other types of lead-covering machines the hydraulic pressure is applied from the top.

The lead is frequently alloyed with a small percentage of tin, about 2 per cent. This was done originally to protect the lead from the attack of acids, &c., but its utility in this respect is questionable. The tin, however, adds a certain amount of rigidity to the cable, which is useful in facilitating the operation of drawing it into the underground ducts. The tin, at the same time, adds a difficulty to the process of lead-covering the cable, the small percentage above mentioned almost doubling the pressure that would be required to put on the lead pure. The rate at which the cable may be lead-covered depends largely on the size of the cable, ranging from a few feet per minute in the case of large cables to several hundred feet per minute for the smaller cables.

The cable is now practically ready for drawing into the underground ducts. Some of the manufacturers of high-tension cables, however, first subject them to a severe breaking-down, or puncture test, by applying an electrical pressure from one and a-half to three or four times the pressure to which the cable will be subjected in actual service. The pressure test varies with the length of time the test is to be applied. Thus, a cable designed to withstand a working pressure of 500 volts may be subjected to a pressure of 2,500 volts for one hour, or to 4,000 volts for a few moments. If intended to withstand a working pressure of 10,000 volts, it may be subjected to 15,000 volts for one hour or to an instantaneous pressure of 30,000 volts. The high pressures for these tests are developed by means of an alternating-current generator and step-up transformers. When the apparatus is ready, the wires leading from it are connected to the conductor, and to the lead cover of the cable, respectively. In the case of rubber cables, these tests are sometimes applied before the lead cover is put on, the cable being immersed in a tank of water. The ends of the cable are, of course, kept out of the water. In this latter case the wires run from the testing machine to the conductor of the cable and to the water in which the cable is immersed. If the cable is defective at any point, or if the pressure is too great for the inherent puncture-resisting quality of the insulating material, the current will "jump" and puncture the cable.

At such high pressures it is obviously essential that much care should be exercised in making these tests. The lead is removed, in the case of rubber cables, for a distance of several inches from the ends of the cable, as, otherwise, when a pressure of 20,000 volts or 25,000 volts is reached, the electricity will creep along the surface of the insulation (as it may be seen to do also on a sheet of thick glass subjected to high pressures), thereby reducing the tension of the current.

The maximum electromotive force used in the city of New York on underground cables is about 6,600 volts. This is employed by the electric traction and electric lighting companies. The longest circuit on which this pressure is used measures about 10 miles, while many other circuits range from 1 mile to 5 miles and 6 miles in length. The maximum electrical energy transmitted over these circuits from the power-houses to the various sub-stations or points of distribution ranges from 1,300 H.P. to 2,700 H P. Both rubber and paper cables are employed for this service. The dimensions of one of these cables may be given; for instance, a three-conductor cable, rubber, now operating at 6,600 volts. Each conductor is made up of 37 copper wires, giving a total cross-section of 250,000 circular mils, equal to 0·5in. diameter. The thickness of the rubber insulating wall around each conductor is $\frac{5}{32}$in. high. This is a rubber-jacketed, or "split" insulation cable. The jacket is also $\frac{5}{32}$in. thick. This ensures $\frac{19}{32}$in. of rubber compound between conductors, and between any conductor and the ground. Each conductor, and also the jacket, is covered with a tape, put on spirally outside of the rubber. The lead-covering of this cable is $\frac{1}{4}$in. thick. The outside diameter of the cable is 2·56in. The interstices between the conductors are filled in with jute.

The highest working pressure for underground cables thus far proposed is that soon to be operated by a Western company in the United States. This company has an electric plant, driven by water-power, from which the current is to be transmitted at a pressure of 25,000 volts, on overhead wires, a distance of about 20 miles to the city limits. From this point to the point of distribution in the city the power is to be transmitted through underground cables, at the same pressure, a distance of 3 miles. This cable consists of three conductors, each of No. 2 B. & S. gauge. The thickness of insulation around each conductor is $\frac{7}{32}$in., and the thickness of the jacket is $\frac{5}{32}$in. The cable is lead covered.

Inasmuch as some authorities consider that 40,000 volts represent the maximum electrical pressure that can be advantageously employed on overhead lines for the transmission of electrical energy on a large scale, it is thought that the safe maximum pressure for underground cables has, perhaps, been reached, if not exceeded, in the installation referred to, owing to the difficulties to be encountered in maintaining the insulation at such high pressures. The operation of this circuit will be watched with much interest, and doubtless by its success or failure the pressure of subsequent installations of a like nature will be measurably gauged.

A DETERMINATION OF THE MECHANICAL EQUIVALENT OF HEAT.

BY DR. HOWARD TURNER BARNES.*

The method employed is that proposed three years ago by Prof. Callendar and the author at the British Association meeting at Toronto. In essence it consists in warming by a steady, measured supply of electrical energy, the volume of water passing at a constant determinate rate through a short small-bore glass tube containing the current-conveying wire. The small-bore tube connects two larger

* Abstract of a Paper, "On the Capacity for Heat of Water between the Freezing and Boiling Points, together with a Determination of the Mechanical Equivalent of Heat in Terms of the International Electrical Units," read before the Royal Society, being an account of experiments by the continuous-flow method of calorimetry, performed in the Macdonald Physical Laboratory of McGill University, Montreal.

Digitized by Google

tubes in which are fixed the two members of a pair of differential platinum thermometers. These thermometers are used, when everything has become steady, to measure the difference between the temperatures of the water entering and leaving the middle small tube.

A glass vacuum jacket, itself surrounded by a copper jacket containing water at the inflow temperature, embraces this middle tube; and thus the heat lost by radiation from the water as it is warmed in and flows from the tube is reduced to a small yet measureable amount. Errors in the final results arising from this loss of heat by radiation, from the loss of heat by conduction, from the tendency of the water to follow unvarying stream-lines, and from the thermal capacity of the apparatus, with others of smaller import, were all estimated and allowed for. The most important of the measurements involved are the electrical; and the accuracy of these depends ultimately upon the accuracy of an international standard resistance and upon that of the voltage assigned to a Clark cell. The Clark cells employed in the present series of experiments gave values agreeing with all the best results obtained in setting up this electro-chemical combination.

The results of the experiments, which extended over a year, are given in 55 tables. From these the author constructs another table of the values of the specific heat of water at temperatures between 0°C. and 100°C. differing by 5°C. In terms of a thermal unit at 16°C. the specific heat at 5°C. is 1·00530, at 40°C. is 0·99735, and at 95°C. is 1·00370. It is a minimum at 37·5°C. In terms of the thermal unit at 16°C. the mechanical equivalent is 4·18876 joules—about 0·132 per cent. higher than that obtained by Reynolds and Moorby in their direct mechanical method. This discrepancy is due, the author concludes, to the fact that the E.M.F. of his standard Clark cell should be taken as 1·43325 int. volts, and not as 1·43420 volts, as used in his calculations. With this new value for the E.M.F. of the Clark cell, the author's results come into most excellent accord with those obtained by Prof. Rowland. The author, however, ascribes the slight differences still existing between his results and the results obtained by the electrical methods of Griffiths and of Schuster and Gannon to the radical difference in the methods of calorimetry.

Atmospheric Electricity and Dew-ponds.—Writing to *Nature* Mr. Arthur Marshall, of the Chemical Department of Woolwich Arsenal, describes as follows some interesting experiments designed to throw light on this subject:—

On the chalk hills in the south-east of England there are a number of ponds known as dew-ponds. One of these was described by Gilbert White ("Natural History of Selborne," Letter 29). There is a pond of considerable size at one of the highest points of the main ridge of the South Downs close to Chanctonbury Ring. From its position it is obvious that this pond can only be fed by water precipitated into it directly from the air. Yet it always contains a considerable volume of water. At the end of the dry weather last year, when most of the ponds in the valleys were empty, this dew-pond still contained several thousand gallons. How does this pond obtain the enormous quantities of water necessary to compensate for the rapid evaporation in such an exposed position, and also to supply large flocks of sheep?

It appeared to me that there was but one possible explanation: A difference of electrical potential must cause an attraction between the particles of moisture and the summit of the hill upon which the pond is situated. It is, of course, well known that drops of rain, &c., usually have an electrical charge, but it was necessary to ascertain whether this was capable of producing such a great effect. In order to test this point I took two porcelain basins of equal size and suspended them by means of silk threads from stakes driven into the ground at a high part of the ridge of the South Downs. In each of these basins was fixed an upright piece of sheet copper. The two pieces of apparatus were placed in exactly similar positions and were in every respect identical, except that in the one case the copper screen was connected to earth by means of a wire, whereas in the other case it was insulated by the silk threads.

The apparatus was left thus during the night of April 1, 1899. There was a thick mist on the hills, so much so that I was unable to select the most favourable position for the apparatus. In the morning the amount of water in the two basins was measured. In the basin with the insulated screen there were 15·5cc. of water; in that with the screen connected to earth there were 18·0cc. This clearly confirmed my theory, for the insulated apparatus would tend to acquire an electrical charge from the particles of moisture. Consequently the attraction would be less than in the case of the apparatus which was not insulated. The insulation must have been very imperfect, for the silk became saturated with moisture as soon as the apparatus was erected. The position chosen also, was not so favourable as it might have been. Nevertheless, there was a difference of 16 per cent. in the quantities of moisture collected.

POWER GENERATION: COMPARATIVE COST BY THE STEAM ENGINE, WATER TURBINE, AND GAS ENGINE.*

BY J. B. C. KERSHAW, F.I.C.

There is no question of greater importance at the present moment to those engaged in the management of our manufacturing industries than that of power generation. The supremacy which the steam engine has so long enjoyed is now assailed from two sides. The water turbine and the gas engine have become dangerous rivals; and there are those who assert that early in the twentieth century we may expect to find the steam engine ousted from its place as the most economical prime mover by one or other of these later forms of power generator. During the past 10 years a most remarkable development of hydraulic power has been taking place on the Continent of Europe and in America. The large power installations in the Haute-Savoie in France, at Rheinfelden in Germany, and at Niagara in America, have already become of considerable industrial importance. The success which has attended these earlier installations of turbines and dynamos, operated by water-power, has led to the exploitation of numberless schemes of a similar character. The aggregate amount of power at the present date generated from falling water forms no inconsiderable portion of the total power utilised in manufacturing industries; and two years ago it was estimated by the writer to be between 236,000 H.P. and 350,000 H.P.† On the other hand, gas engineers have been busily engaged in working out the problems presented by large gas engines, and by the utilisation of the waste gases of blast furnaces. Trials which have been made during recent years, show that both of these problems are capable of successful solution. Gas engines up to 650 H.P. have been built and have worked smoothly and economically; while at Seraing, in Belgium, and at other places, the blast furnace gases have been utilised for driving the engines which supply the blast.

The question, therefore, which the engineer now has to settle, when deciding upon the site and locality for a new factory, or when deciding upon the system of power generation to adopt for extensions of the old, is no longer so simple as when only one method of power generation in large units was open to him. It is no doubt true that the choice between the three possible sources of power is one, which in many cases will be settled purely by local considerations; and the proximity of a large waterfall, or of an extensive coal field, to the factory will be held to point to the turbine, or to the steam engine, as the most economical power generator.‡ In a great number of cases, however, especially when the decision of the engineer covers the choice of a site for the factory, the problem is capable of no such easy solution; and the most economical source of power can only be determined after an exhaustive study of comparative costs data. There has been an immense mass of information bearing on this subject, published in recent years, but no attempts have been made to co-ordinate these facts and data; and comparison between them in their existing form is unproductive of any useful results.

The aim of the writer in the present Paper has, therefore, been to collect and arrange in comparable form some of the more important figures bearing on the cost of power generation. Full references are given to all the original articles from which these figures are drawn, and it is hoped that this summary of a large mass of scattered information may be of considerable service to all interested in the question.

I.—Steam Power.

1. Estimate by Dr. Emery of cost of electrical horse-power-hour with coal at 12s. 6d. per ton, and interest charges at 5 per cent. Cost varies between 0·347d. and 1·22d., being lowest with 500 H.P. triple-expansion engines. This estimate is for United States of America conditions of labour.—(*Street Railway Review*, 1897, p. 391.)

2. Inquiry by Sheldon into *actual costs* of power in New England mills. The minimum and maximum costs found by the investigator were:—

(*a*) For 365 × 24 hours per annum, $45.69 to $261.00.
(*b*) For 307 × 10 hours per annum, $11.64§ to $14.85.

—(Abstract from "Engineering Record," *Electrical Review* (London), Vol. XLI., p. 314.)

3. Similar inquiry by H. A. Foster. The costs at the 22 plants which were examined varied between the following limits:—For 308 × 10 hours per annum, $15 29 to $200.53 (*Electrical Review* (London), Vol. XLI., p. 421).

* Paper read before Section G of the British Association at Bradford.

† See *Lightning*, January 20, 1898. Also estimate of 200,000 H.P. for United States of America, by Washington, in Paper read before Franklin Institute, July, 1899.

‡ The question of freight charges, and of proximity to markets for the manufactured goods, also requires attention before a decision is taken, but this question is outside the scope of the present Paper.

§ (Fuel 7s. 4d. per ton. Engine, 1,100 H.P.)

Digitized by Google

4. Estimate by Raworth of cost, using superheated steam with best types of modern engines and boilers. Schmidt or Universal engine, using 11b. coal (8lb. steam) per indicated horse-power-hour and coal at 7s. per ton, taken as basis of calculation. Cost per indicated horse-power-year (365 × 24 hours) = £3. 14s. or 0·101d. per indicated horse-power-hour.—(Presidential Address, Northern Society Electrical Engineers, 1898.)

5. Paper by Dr. Bowman on "Power Generation." States that with a 500 H.P. compound condensing engine, the actual cost in a South Lancashire chemical works was £4. 3s. 3d. per indicated horse-power-year (2,825 hours).—(*Jour.* Soc. Chem. Industry, December, 1897.)

6. Inquiry by H. A. Mavor as to actual costs of steam power in the United Kingdom. Average of 10 factories generating in large units 0·130d. per indicated horse-power-hour; coal 5s. 5d. per ton. Best result of these 10 obtained by a weaving mill using power generated by two 375 H.P. engines, and coal at 4s. 10d. per ton. Cost in this case only 0·072d. per indicated horse-power-hour.—(Paper read before Institution Engineers and Shipbuilders in Scotland, March, 1898.)

7. Details by A. Siemens, Esq., of actual cost of electrical power at Charlton Works. Cost works out to 1·287d. per kilowatt-hour at the switchboard of the generating plant.—(British Association Paper, Bristol Meeting, *Electrical Review*, September 16, 1898, p. 407.)

8. Estimate by Prof. Kennedy of cost of electrical energy from steam power in Scotland, with coal at 3s. 6d. per ton. The average cost is given as £9 per electrical horse-power-year.—(*Jour.* Soc. Chem. Industry, 1898, p. 314.)

9. Paper by Webber upon comparative costs of water and steam-power. Gives detailed estimate of cost of latter with 1,000 H.P. plant. With coal at $3.85 per ton, cost equals $17.84 per indicated horse-power-year.

The best actual results known to author were with an engine running with an average load of 1,950 H.P., and coal at $2.26 per ton (d/d.). Cost worked out to $11.55 per indicated horse-power per annum. These estimates are for a year of 3,070 working hours. —(*Engineering Magazine*, Vol. XV., p. 922.)

10. The actual cost of steam power in Switzerland, in the cantonal district of Zurich, lies between 224fr. and 635fr. per indicated horse-power-year.—(*Electricity* (New York), from *Le Genie Civil*, March 15, 1899.)

11. The actual cost of power for the electric street railway in Montreal is stated by Cunningham to be slightly under 0·25d. per kilowatt-hour.—(*Engineering*, June 16, 1899.)

12. Estimate by Kershaw of cost of the electrical horse-power-hour, using best types of engines and dynamos, and coal at 7s. per ton. Cost worked out to 0·141d.—(*The Electrician*, December 25, 1896.)

13. In his evidence before the House of Commons Committee on the Power Bills, Mr. Harris, of Bramwell and Harris, stated that at Liverpool the cost of power for the overhead railway had varied between 0·53d. and 0·31d. per unit.—(*Lightning*, July 5, 1900.)

14. Mr. Philip Dawson, in *Engineering*, has tabulated a large number of costs data for generating stations in Europe and America. The lowest costs for generating the kilowatt-hour for tramway work is given in Table I. as 0·1275d.—(*Engineering*, June 1, 1900.)

Table I.—*Actual Costs of Steam Power per Indicated Horse-Power-Year of* 8,760 *Hours.*

Country.	Cost.	Remarks.	Ref. No.
America	£3 12 10	Compiled from lowest items in any stations	14
United Kingdom ...	3 14 0	Engines 375 H.P., coal 4s. 10s. per ton, weaving mill	6
United Kingdom ...	4 14 10	Average of 10 factories generating in large units	6
Canada (Montreal).	5 1 9	Generating station of electric street railroad	11
America	6 2 6	Engines 1,100 H.P., coal 7s. 4d. per ton, cotton mill	2
America	6 6 3	Engine 1,950 H.P., coal 9s. 5d. per ton	9
United Kingdom (Liverpool)	6 6 3	Generating station of overhead railway	13
America	7 19 0	Cotton mill.....	3
Switzerland	9 0 0	Lowest cost of steam power	10
United Kingdom (S. Lancashire)	12 17 2	Actual cost in chemical works.....	5
United Kingdom (Woolwich)	26 5 1	Cost at switchboard in cable works	7

In order that these estimates and actual costs may be compared, the lowest costs noted by each authority have been converted into costs per indicated horse-power-year of 8,760 hours, and gathered into Tables I. and II. The relationship between the cost of the indicated horse-power-year and of the electrical horse-power-year has been taken as 75:100, an energy efficiency of 85 per cent. being assumed in the combined machinery; the management, interest, and depreciation charges on the increased capital expenditure for dynamos making up the balance. The ratio of interest and depreciation charges to running charges has been taken as 40 to 100, in the two cases where these are known to have been omitted from the estimates of cost. Where the data have permitted it, allowance has been made for the fact that interest charges remain stationary, whether a 10-hour or 24-hour day is worked. The most remarkable fact about these costs, when studied in this way, is their wide variation. That the cost of steam-power should be high in Switzerland where no coalfields exist, is not surprising; but one would hardly expect to find the cost in Switzerland exceeded by that found in certain South Lancashire and Metropolitan works.

The details of two of the lowest costs, namely, Dawson's for the lowest practicable cost of generation in the United States of America, and Raworth's estimate for a South Lancashire central power station, using superheated steam, are given below, since it is of interest to have these two sets of figures brought prominently forward. The wide gap that separates these from the greater number of figures in Table I., is the measure of the improvement possible in power generation by steam.

Table II.—*Estimated Costs of Steam Power per Indicated Horse-Power-Year of* 8,760 *Hours.*

Authority.	Cost.	Remarks.	Ref. No.
Raworth	£3 14 0	Superheated steam. Coal 7s. per ton	4
Kershaw	3 18 0	Coal 7s. per ton.....	12
Kennedy	6 15 0	Coal 3s. 6d. per ton	8
Webber.....	8 17 4	Coal 16s. per ton	9
Emery	9 9 11	Coal 12s. 6d. per ton	1

The reference numbers in these and the following tables refer to the details given in Sections I, II., and III. of this Paper.

Dawson's estimate for the lowest practicable costs of generation, obtained by compiling a return which includes the lowest cost of each item attained in *any* generating plant in the United States of America:—

	Per B.T.U.	Per kw.-year of 8,760 hours.
Fuel	0·090d.	£3 5 8
Wages and salaries	0·030d.	1 1 10
Oil, waste, stores	0·005d.	0 3 8
Maintenance	0·0025d.	0 1 10
Total	0·1275d.	£4 13 0

—(*Electrical Review*, July 6, 1900).

Raworth's estimate of cost of steam power, by use of highly superheated steam in combination with suitable steam engine. (Universal or Schmidt.) *Basis.*—50,000 H.P. plant. Coal at 7s. per ton. 8,760 hours per annum.

Coal, 4 tons at 7s.....	£1 8 0	
Margin for bad coal and starting boilers, 25 per cent.	0 7 0	
Labour and management	0 10 0	
Repairs and stores.....	0 7 6	
Total operating expenses		£2 12 6
Interest, 5 per cent.	0 12 0	
Depreciation (average on total capital, 4 per cent.).....	0 9 6	
Total fixed charges		1 1 6
Total per indicated horse-power-year		£3 14 0

The capital outlay, including land, buildings, and 20 per cent. spare, is taken at £12 per horse-power.

(To be concluded.)

"Compression Splices."—An American firm has recently brought out a compression apparatus for producing joints in wires and cables by simple compression and without solder. In one form the apparatus consists of a 75-ton press, the hydraulic pump being located on a small truck with a crane attached so that the press can be lowered into a manhole for splicing the feeder cables which occupy the ducts of underground conduits. Recently a smaller and more portable form has been brought out in which a 20-ton press is used with an independent hydraulic pump and flexible connection. The press is said to be capable of exerting a pressure of 40,000lb., yet the press alone, with its splicing dies, weighs only 14lb., the pump 15lb., and the connector and couplings about 11b. This apparatus is intended for wire to a maximum size of No. 0 S.W.G., and can make T and Y joints as well as straight-through joints.

CORRESPONDENCE.

COHERERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: May not the cases of cohesion mentioned in Prof. Lodge's letter in the last number of *The Electrician* be one aspect of a many-sided phenomenon?

From the fact that the diminution or increase of resistance under electric radiation depends on the chemical nature of the substance, and from the further fact that there is in many cases an after-recovery, it would appear that that phenomenon is one of molecular strain.

It is evident that the molecularly-strained substance should undergo a physico-chemical modification of its properties. Take, for example, the modification of yellow phosphorus into the red variety under the action of visible radiation. Here we find the following apparently diverse effects as results of the same molecular strain:—

1. The substance becomes *chemically* less active.
2. It becomes of a higher specific gravity.
3. Its electric conductivity is increased.
4. It becomes insoluble in CS_2.

As another illustration of the change of physical properties due to molecular strain under radiation, the variation of *adhesive* power may be mentioned. This is seen in Daguerreotype plates, where mercury vapour used in the development of the latent image adheres to the light-impressed portions only. Similar developments by water vapour are also well known.

If we have in some cases a variation of adhesive power by radiation, why not in other cases a variation of power of *cohesion?* The phosphorus exposed to light has its density increased, evidently by the mutual approach of its molecules. Is this due to an increase of cohesion?—Yours, &c.,

London, October 15. J. C. BOSE.

THE EFFICIENCY OF THE CONTINUOUS-CURRENT ARC.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: At the beginning of your leading article on "The Efficiency of the Continuous-Current Arc," in your issue of October 12, you attribute the discovery of the entire phenomena in question to Prof. Carhart and myself, and only credit Mrs. Ayrton with having found out the explanation. This, however, is far from being the fact. What we published at the Chicago Congress in 1893 was, that, when a fixed direct current passed between given carbons, the mean spherical candle-power increased until a certain P.D., as Prof. Carhart put it, or until a certain length of arc, as I stated it, was reached, and then the candle-power decreased again. But, that a short arc sends out more light than even a somewhat larger one, and that this quite short arc converts more of the power developed by the dynamo into *useful* light than an arc of any other length, are new and unsuspected facts, the discovery of which is entirely due to Mrs. Ayrton's observation as are their scientific explanation to her intuition.—Yours, &c., W. E. AYRTON.

MUNICIPAL, FOREIGN & GENERAL NOTES.

Airdree.—The Scottish House-to-House Electricity Co. have acquired the New General Traction Co.'s parliamentary powers for the construction of electric tramways in this town. The Scottish Company are now applying for similar powers for the adjoining burgh of Coatbridge. The Airdrie Council are recommended to transfer their provisional electric lighting order to the company, who will then have electric lighting and traction powers for Airdrie and Coatbridge.

Alleged Receiving of Stolen Property.—Two brothers, Harry and John Thomas Simpson, trading as Thomas Simpson, brass founders, Orange-street, Halifax, were charged last week with receiving a large quantity of telephone wire, the property of the National Telephone Co., knowing the same to have been stolen. The case was a sequel to a charge of burglary against two labourers named Barnham and Broadbent of entering the premises of the National Company in Raglan-street, Halifax, and stealing therefrom a large quantity of goods. The evidence went to show that the prisoners had received the stolen property, but this was denied by both of them. After evidence had been given the prisoners pleaded not guilty, and were committed for trial, bail being allowed.

Automobile Exhibition.—An exhibition of automobile vehicles was held at Chicago from Sept. 18 to Sept. 22, and attracted a very large number of visitors. No European firms were represented. Electric machines were in the great majority and in large variety. Several neat and handy delivery waggons were exhibited, as well as the usual types of carriages—hansoms, broughams, victorias, and buggies. The majority of the racing machines were gas driven, but several small, high-speed, steam-driven vehicles were also exhibited.

Barry.—A special meeting of the Council has been summoned to consider the question of applying for a provisional order.

Bermondsey (London).—The Vestry have instructed their consulting engineers (Messrs. Kincaid, Waller and Manville) to prepare a specification for the supply of arc lamps and columns, for which tenders are to be invited.

Bexhill.—The advisability of adopting a system of "free" wiring of premises is to be considered by the Electric Light committee.

Birmingham.—A special Tramways committee has been constituted by the Council. Hitherto traction matters have been dealt with by the Public Works committee.

Blairgowrie.—The Council are to confer with Mr. W. C. C. Hawtayne on the electric lighting question.

Brighton.—The resident electrical engineer (Mr. J. Christie) has submitted an estimate of the further capital expenditure required for the electricity undertaking during 1901-2. His estimate for machinery and plant is £26,500—£15,000 for two steam dynamos and switch gear, £2,500 for a condenser, with pumps and connections, and £9,000 for three boilers and accessories; while £28,500 will be needed for mains and house service connections, £11,500 for new feeders, £5,000 for new distributors, and £12,000 for house services and meters, leaving £1,500 for contingencies. The town council have applied for sanction to borrow £56,500 to cover this work.

Brisbane (Queensland).—The result of the poll of ratepayers on the question as to whether the Municipality should itself undertake the erection of electricity works or lease its powers to a company is a majority of 229 in favour of the latter proposal. Only a small percentage of the ratepayers voted.

Cardiff.—The Tramways committee, acting on the advice of their electric tramway engineer (Mr. Arthur Ellis), recommend the Council to undertake the track equipment themselves, and that Mr. Ellis be authorised to appoint his own chief assistant at a commencing salary of £225, rising to a maximum of £300 by annual increments of £25. By this arrangement, it is calculated a saving of between £5,000 and £6,000 will be effected.

The Electricity committee are considering the advisability of adopting a system of "free" wiring in the district.

Chatham.—It was announced at the last meeting of the Council that the Chatham and District Light Railways Co. had deposited a cheque for £6,000 under the Chatham and District Light Railway Order, and that the construction of the electric tramways would shortly be proceeded with.

Chelsea (London).—At the Vestry meeting last week the surveyor (Mr. T. W. E. Higgens) submitted a communication asking permission "to erect wires on the lamp-posts in King's-road, and Lower Sloane-street, from World's End towards Victoria, for the purpose of running electric cars." Mr. Higgens said that if the system were as sound as the invention declared it to be it would afford the solution of many difficulties now experienced, and he suggested that the matter be referred to the Works committee, but upon the motion of Major Doll it was agreed that the consideration of the project be adjourned for 12 months.

Chesterfield.—The maximum demand system of charging for electric current is to be adopted. The charge for the first hour's maximum demand will be 7d. per unit and 3d. after. For power the charge will be 3d. after 4 p.m., and between midnight and 4 p.m. 1½d. Consumers are to be allowed, if they so desire, instead of doing the wiring themselves, to have the work carried out by contractors under the Corporation to the satisfaction of the resident engineer, and to pay off the cost of such work by paying an extra 1d. per unit on the quantity consumed, or in the alternative to pay off the amount by 20 quarterly payments, carrying interest at 5 per cent. on the balance owing. The Watch committee have been offered arc lamps for lighting the Market-place at a cost equal to the amount now paid for gas.

Chivilcoy (Argentina).—The local gas company recently decided to establish electricity works.

City of London.—At the meeting of the Common Council last week, the consideration of the recommendations of the Streets committee as to the testing of electricity meters, and the increase of the salary of the electrical inspector (Mr. A. A. Voysey), referred to in our last issue, was postponed.

Digitized by Google

Cleethorpes.—Mr. C. S. Vesey Brown has been appointed consulting electrical engineer.

Coatbridge.—Mr. W. M. Murphy has declined to sign the agreement for the construction of an electric tramway, and the Council have now made an agreement with the Scottish House-to-House Electricity Co., who propose to apply for parliamentary powers to construct tramways in Coatbridge and Airdrie.

Corrientes (Argentina)—A proposal to erect electricity works is under the consideration of the Municipal Council.

Croydon.—Owing to the increase in the price of coal the charge for public arc lamps has been increased from £18 to £21 each per annum. There are at present 135 arcs.

Dorchester.—A provisional order is to be applied for by the Council.

Dungannon.—A provisional electric lighting order is to be applied for by the District Council.

East Cowes (Isle of Wight.)—The application of Edmundson's Electricity Corporation (Ltd.) for sanction to a provisional order is to be considered by the Council.

Eccles.—Application has been made for sanction to borrow £5,308 for electric lighting.

Edinburgh.—The Council on Wednesday discussed the question of cabling the Portobello tramway route. Estimates were presented for £20,000 for the erection of a cable power station at Portobello. Mr. Gray said that cabling was not the proper motive power for tramways on the Portobello section, and that electricity should be tried. Mr. Kellock, in seconding, said no doubt the underground system was expensive, and he therefore suggested the adoption of the trolley system. They could provide the overhead trolley system for the sum they were voting for the cable power station. Everywhere the cable system was being abandoned except in Edinburgh. Mr. Steel (a builder) said it was too late in the day to come forward and stop the works. He denied that electric haulage was better than the cable system. After further discussion, however, the motion for approval of the estimates was carried.

The accounts of the Electricity department for the year ended May 15 have been issued. The total receipts for public and private lighting, meter rental, &c., amount to £63,659. 9s. The expenditure amounted to £32,686. 19s. 10d., leaving a gross profit of £30,972. 9s. 2d. After taking into account the balance from the previous year (£5,886), and after payment of interest (£13,178. 14s. 2d.), and sinking fund instalment (£14,119. 5s. 8d.), and setting aside £5,886. 9s. 6d. for reserve, there was a balance of £3,674. 9s. 4d., which has been carried forward. The total capital expenditure to date is £595,655. 8s. 1d., and of this sum £200,298. 16s. 3d. was expended during the past year. 6,273,397 units of electric current were generated, of which 3,780,343 were sold for private lighting, 579,612 for motive power, 1,191,773 were supplied for arc lighting, and 329,903 were used on the works.

Edmonton.—A special meeting of the Council is to be held to pass a resolution in favour of applying for a provisional electric lighting order.

Electric Traction in France.—The Compagnie Générale de Traction has sent us an interesting and well-illustrated pamphlet descriptive of several of the electric tramways built by them. This company, which is connected with the Westinghouse Company, has done a great deal of excellent work, including the equipment of the power station which drives the electrical extension of the Western Railway of France into Paris, and also provides the energy for the moving platform and electric railway in the exhibition. The pamphlet also includes an interesting description, with typical illustrations, of a tramway built in Alexandria (Egypt).

Featherstone.—The Council are seeking assistance from the neighbouring local authorities in opposing the proposals of the Northern Counties Electric Supply Co. to establish electricity works in the district.

Gloucester.—The Council are recommended to acquire the undertaking of the local tramways company and to convert the lines to electric traction. At present the only difficulty is the terms upon which the Corporation will supply the company with electric current.

Guisborough.—The Council have unanimously resolved to oppose the Northern Counties Electricity Supply Co.'s application for a provisional order.

Harrogate.—Application has been made for sanction to a further loan of £10,000 for electric lighting extensions. The net profit on the undertaking for the past year, after payment of interest and sinking fund, was £777, against a deficit of £729 in the previous year.

Hawthorn (Victoria).—The Council has given up its proposal to establish municipal electricity works, and the provisional order has been transferred to the Electric Lighting and Traction Co. for £150.

Hebburn.—Mr. J. A. Jeckell (of South Shields) has been asked to submit terms for preparing plans and estimates for an electricity supply scheme. A canvass of manufacturers and ship builders in the district is being made to ascertain their probable requirements in regard to a supply of current for lighting and power.

Hexham—Opposition is to be offered to the application of the Northern Counties Electricity Supply Co. for a provisional order.

Holyhead.—Electric lighting was again discussed by the District Council last week. It was reported that between the island of Anglesey and Holy Isle there is a culvert through which the sea rushes with considerable force, the period of rest being only one hour in 24. Mr. Thunderbolt (hydraulic engineer) had assured the Council that there was enough power in the rush of these waters to generate electricity to illuminate Anglesey. Mr. Thunderbolt is to prepare a report which will be submitted to the Council at the next meeting, when, if favourable, the question of applying for parliamentary powers will be considered.

Hornsey (Middlesex).—Col. C. H. Luard, R.E., held an enquiry on Friday last into the application of the District Council for a loan of £73,500 for electric lighting for this district. A large number of local residents, tradesmen, and property owners supported the proposal that the District Council should have control of the electric lighting, especially as electric lighting was profitably established at Islington and St. Pancras—adjoining districts. Gas is 3s. per 1,000ft. as supplied by the Hornsey Gas Co., and by the Gas Light and Coke Co. 3s. 5d. The scheme of electric lighting proposed at Hornsey is due to Mr. Robert Hammond, who is consulting engineer to the Council. He proposed the three-wire continuous current at 480 volts. The public lighting will include 94 arc lamps. The revenue from private lighting at an average of 5d. per unit is estimated at £9,775, and from public lighting at £1,787; the cost of generation at 2·25d. per unit, interest and sinking fund £,4226, leaving a net profit of £1,764 per annum upon 539,000 units generated. The station will adjoin the Great Northern Railway. The population of Hornsey is 80,000.

Huddersfield.—At the meeting of the Corporation on Wednesday Mr. Berry drew attention to the deficit of £2,068. 10s. 2d. on the working of the Tramways department for the past half-year. Ald. Walker pointed out that the deficiency was made up by taking into account sinking fund and interest on money borrowed. The tramways were not losing money but were making a profit. Ald. Kendall considered it a strong reason why the conversion to electric traction should be hurried on, for they were paying interest on money that was earning nothing.

Ilford.—The consulting engineer (Mr. W. C. C. Hawtayne) has been requested to prepare estimates of the cost of extending the electric lighting mains.

Inverness.—The dispute between the Council and its late consulting engineer (Mr. E. G. Craven) is likely to be settled amicably. The Finance sub-committee, which was appointed to report on the account submitted by Mr. Craven, and after consideration of all the circumstances, they recommend that he be paid 2½ per cent. on the total cost (£27,000) of the scheme which was provisionally accepted. They further recommend that the claim of £59. 4s. 9d., incurred by Mr. Craven for outlays and expenses be also paid, making the total £734. 4s. 9d., of which £300 has already been paid on account.

Launceston.—Owing to a quarrel with the gas company the surveyor (Mr. Thorp) has been instructed to make inquiries as to the cost of electric lighting and other forms of illumination.

Leigh.—The Council have instructed the town clerk, borough surveyor and electrical engineer to prepare a report upon the advisability of (1) constructing and working tramways; (2) constructing and leasing same; (3) permitting a company to contsruct and work same.

Light Railways.—An inquiry was recently held at Newcastle into the application of the British Electric Traction Co. for an order to construct a light (electric) railway between Jarrow and South Shields. Mr. Morse appeared for the promoters, and there was opposition as to the gauge of the proposed line. The promoters specified the standard, but the local tramway is constructed to a 3ft. 6in. gauge. Mr. S. Sellon said the total length of the tramway was a little over 3¼ miles, and the overhead trolley system would be adopted. The South Shields Corporation opposed, and Mr. Burgess, borough engineer, stated that his experience was that 3ft. 6in. gauges were better for tramway tracks through public streets than 4ft. 8in. gauges, and Mr. Laws, city engineer of Newcastle, concurred in this. In the first place, there was the question of "rutting," which was a very serious one. It was impossible to repair "rutting." The Commissioners will report in due course.

The Light Railway Commissioners held an inquiry at Kidderminster on Wednesday into the application of the Kidderminster and Stourport Electric Tramway Co. for powers to construct a line from Kidderminster to Bewdley with a branch to Franche. Mr. S. Morse appeared for the promoters, and said the line would be nearly 4½ miles long, and the same system of traction would be adopted as that employed on the Kidderminster-Stourport line. Evidence having been given in favour of the application, technical details were supplied by Mr. W. R. P. Hederstedt, representing Mr. S. Sellon.

Digitized by Google

An inquiry was held at Sheffield on Friday into the application of the British Electric Traction Co. to construct an electric tramway a little over 4 miles in length between Barnsley, Worsbro' and Hoyland. The scheme is an extension of the Barnsley electric tramways authorised last Session. The tramway will follow the main road from Barnsley towards Sheffield to Hoyland Common, passing through Worsbro' Bridge and Birdwell. Mr. Sydney Morse appeared for the promoters, and technical details were supplied by Mr. Stephen Sellon. The Great Central Railway Co. opposed, urging that they would be seriously interfered with in the working of their line, because it was intended shortly to ask the Board of Trade to permit its use for passenger as well as mineral traffic, and there was cause for apprehension that if the proposed light railway was made to cross the Great Central Railway at Worsbro' Bridge, the Board would refuse to sanction its being used for passenger traffic. Counsel for the railway company also asked them to consider the danger to passengers on the light railway that would arise from their being carried over a railway level crossing, especially if, as the promoters proposed, the light railway crossed the metals at right angles, instead of with an S curve. After hearing the evidence, Lord Jersey intimated that the Commissioners were willing to grant the order, including the level crossing, but they thought a clause should be put in to the effect that any extra expense which the Board of Trade might put the Great Central Company to in consequence of the light railway crossing their line, should be thrown upon the promoters, at least to such extent as the Board thought reasonable.

The Dartford District Light Railways order has been submitted to the Board of Trade for confirmation. Objections by Nov. 3.

The Rhyl and Prestatyn Light Railways Extensions Order has also been submitted to the Board of Trade for confirmation. Objections by Nov. 10.

Liverpool.—At Wednesday's Corporation meeting it was decided to apply for a provisional order to authorise the construction of additional electric tramways.

Mr. S. W. Higginbottom, M.P., made an interesting statement at the last meeting of the Electric Power and Lighting committee on the present position of the electrical department. During the present year the first half of the Pumpfields station had been fully equipped with five 1,200 H.P. machines, which were now in working order. The buildings of the Lister-drive station had been completed, and the supply of electric energy from that station was commenced on Aug. 5, and three 1,200 H.P. generators were in working order. The sub-stations at Cobb's Quarry and Fairclough-lane were practically completed, and electric energy was supplied from them. The capacity of the steam plant in use by the department was now more than 20,000 H.P., or double that of 12 months ago. The equivalent number of 16 c.p. incandescent lamps connected to the supply mains was 134,000 on Oct. 1, against 108,000 last year. The total number of units sold during 1899 was 5,700,000. Electric energy was now being supplied to the tramways at the rate of 8,000,000 units, and for other purposes at the rate of about 5,000,000 units per annum. There were 142 arc and 288 incandescent electric lamps used for public lighting.

London County Council.—At Tuesday's meeting a loan of £3,100 to Islington for electric lighting was sanctioned.

The Highways committee reported that the Council had decided to seek parliamentary powers for the construction of new tramways (No. 14), one of which was from York-road to High-street, Tooting. The Wimbledon Council had since intimated that it proposes to seek powers next session for the construction of tramways, for a system of electric traction, from near the Wimbledon railway station to the county boundary at Waterfall bridge; and the Wimbledon Council suggested that the County Council should seek powers for the construction of tramways from the present tramway terminus at High-street, Tooting, to Waterfall bridge to connect with the proposed tramways at Wimbledon. This line, if constructed, would form an extension to the county boundary of the tramway (No. 14) above referred to. It was estimated that the cost of construction of this proposed extension (about 3 furlongs) would be about £11,250. The Wimbledon Council is prepared, in the event of the necessary powers being granted, to construct its tramcars for the same system of traction as that which the Council may adopt, and to lease the Wimbledon tramways to the County Council, or to enter into an agreement for mutual running powers, or for any other arrangement which might be agreed upon between the County Council and Wimbledon. The committee recommended that the Council apply for powers to carry out the work. The report stood over for a week.

The Highways committee also reported on the result of the question of the alteration from 100 volts to 200 volts of the standard pressure given by the City of London Electric Lighting Co. in respect to their Southwark Electric Lighting Order, 1891. The Council gave permission subject to 12 conditions, but the company were unwilling to accept the conditions, and appealed to the Board of Trade. After having held an inquiry the Board had issued its award, in which only the first of the 12 conditions was allowed. This condition was, shortly, that any necessary alterations to the wirings or fittings on a consumer's premises, and the repair of any damage incidental to such alterations, shall be carried out by the company at its own cost, and makes provision for reference to arbitration in case of dispute between the company and a consumer.

In May last the magistrate at Southwark dismissed six summonses taken out by the Council against the London Electric Supply Corporation for not maintaining a constant supply of electric energy. The magistrate stated a case, but the company had stated that it was very improbable that there would be any failure of supply in the future, and had asked that further proceedings might be abandoned. The Highways committee recommended this course, and this was agreed to.

Manchester.—The Manchester Corporation General Powers Bill (1901), in which powers are to be sought for the construction of additional electric tramways, has been approved by a meeting of ratepayers.

Marylebone (London).—The question of the purchase by the Marylebone Vestry of the portion of the undertaking of the Metropolitan Electric Supply Co. situate in the parish of Marylebone, at an estimated cost of between £900,000 and £1,000,000, was again discussed at the meeting of the Vestry last week. Mr. White, L.C.C., moved

"That the Vestry non-confirm that part of the minutes of August 2, 1900,* which related to the proposed purchase of the Marylebone undertaking of the Metropolitan Electric Supply Co., and which empowered the advisory Special Electric Lighting committee to conclude negotiations with the company for the transfer of its undertaking under the West London (Marylebone) Electric Lighting Order, as embodied in the provisional agreement dated 25th June, 1900, it being a condition of the contract that the figures supplied by the company be verified by a chartered accountant and an expert electrical engineer to be employed by the Vestry."

Mr. WHITE said the Vestry probably had never had a matter of such great importance before them—certainly nothing ever involving anything like the expenditure the scheme entailed, and he thought the Vestry would do well to give it calm and dispassionate consideration before they agreed to confirm the minutes. The early history of electric lighting in the parish showed that the Vestry had in the past discussed whether they would become themselves electricity supply undertakers or would accept the offer of a company. After careful consideration, and after receiving many applications from companies, they finally decided to come to an arrangement with the Metropolitan Company. Their Parliamentary committee of that period were unanimous, and, after extracting the best possible terms from the company, the committee agreed that the Vestry should not themselves undertake the supply of electricity. No other public authority had, at that time, decided to supply electric current on their own account. It was only later, when local authorities had had the advantage of the experience gained by the Metropolitan Co, and numerous other company pioneers in electric lighting, that some of them ventured to be their own undertakers. Electrical experiments had then passed the pioneer stage. Things went on comfortably for some years, until certain energetic spirits sprang up who wanted them to take over the electric lighting undertaking or run a competing supply. They obtained a new order, but its confirmation was denied them. If the Vestry had obtained confirmation of that order they would not to day have been asked to incur an expenditure involving the charge of a million of money. The Vestry had openly avowed on two separate occasions by their action that there ought to be competition in electricity supply, and the Marylebone Electric Supply Co. came forward last year. A curious state of affairs then arose. Three members of the Vestry were appointed to oppose the new company's bill in Parliament, but, instead, entered into surreptitious negotiations with the Metropolitan Company and virtually said, "If you help us to oppose the bill of the Marylebone Company, we will enter into some arrangement with you to buy out your Marylebone concern." The Vestry would remember that at the early part of last year there was a proposal made for the purpose of buying the undertaking. Accountants were appointed by both parties to inquire and report as to what was a fair amount to pay. The Vestry's accountant's report was much discussed, the £600,000 mentioned as the purchase price being regarded as a ridiculous and outrageous sum. They were unable to consider the question of purchase on that basis. The figure of the company's accountants was, however, roundly £900,000. The Vestry were so dissatisfied, even with the lesser sum of £600,000, that they decided not to consider the proposal at all. Well, the committee of three they had appointed brought up a report advising the Vestry to give all the money the company's accountants stated to be the value of the concern, although the sum put upon it by the Vestry's accountants was one-third less. They were told in this report that they would be well advised to take over the Marylebone area of the Metropolitan Company, as it would involve no direct expenditure—they were to simply issue 5 per cent. or 3 per cent. bonds at the option of the company, obtain the transfer of the undertaking, and pay interest on the capital sum. Those who were responsible for this scheme knew little about procedure in Parliament in such

* See *The Electrician*, August 3, 1900, p. 576.

Digitized by Google

matters or they would not have devised a project which, if carried out, would prove disastrous to the ratepayers. He was also surprised at a statement in the report that a profit of £12,500 would accrue to the Vestry in the first year of the working of its proposed electricity undertaking, but in this estimate there was nothing provided for the redemption of capital, for the sinking fund proposal was the most amusing part of the scheme. It provided for 1 per cent. for sinking fund, but they were not told what was to be done with this 1 per cent. He had gone to the trouble to make some calculations, taking as his basis the figures given in the report he was criticising (which, however, he did not sponsor), but instead of making a profit of £12,500 on their first year's work he apprehended considerable loss, but the calculations made in the report went on increasing the profits of the Metropolitan Company year by year, and if this was to be continued he was afraid to calculate what the company's profits would be 20 years hence. To suppose that the concern would admit of indefinite expansion year after year, as in its earlier stages, was absurd. What they had to do, if they pursued this matter any further, would be to go to Parliament for powers to raise money for a given period. Hitherto Parliament had not sanctioned a longer period than 42 years, but supposing this was extended to 50 years, and they were able to borrow money at 3½ per cent., they would make an annual payment of £53,300 in interest, or £4. 5s. 3½d. per cent. per annum. No mention had been made of the enormous expense involved in providing supplementary stations for supplying the district. They were constantly receiving applications from the Metropolitan Co. for sanction to connect up various parts of the district. The company had two stations in the parish, which were quite insufficient for the work they were called upon to do, and in 1901, when the Vestry takes up this undertaking, if the project now before them were passed, they would have to overtake one-third of the requirements of the district for current. Suppose they had to purchase one-third of the current, and suppose they paid only 2d. per unit for it. He doubted if they would get current supplied to them by the company for that sum, as he failed to see that the company were pledged as to the price at which they would supply current in bulk, and the increase in the price of coal might mean a great deal in this connection. He would, however, take the price at 2d., which was lower than St. Pancras, Islington, or Hampstead, where the vestries generated their own current. The current required would therefore cost them, in round figures, £9,300, and adding the £53,300 for redemption, they had a total of £62,600. In addition, if the increased cost of coal continued, the company's coal bill for the same number of units they now generated would increase by £10,000, and if the undertaking which they were to take over was to produce a net profit of £45,000, as had been calculated, this involved a much larger output and consequently a much greater consumption of coal than would be covered by the £10,000 increased expenditure, and yet they were asked to believe that the profit was to remain at £45,000, and after paying all charges and 1 per cent. sinking fund they were to have a balance profit of £12,500. He submitted, however, that there would be a deficit of £27,600. They had been told that with the profits to be derived from electricity supply they would be able to take 2d. off the rates, but Parliament had declared that no part of the margin of profits derived from electricity supply can be applied in relief of rates, but was to be applied for the benefit of the consumers only. Supposing there were a loss, however, who was to pay this? It was obvious if they once reduced the price of current they could not put it back to a higher price. [At this point Mr. T. H. Brooke-Hitching, the chairman, said that Parliament had not refused to sanction the application of electricity profits to the relief of the rates; this was only a recommendation of a Joint Committee of both Houses, but had not been embodied in any act of Parliament. As a matter of fact, local authorities owning electricity undertakings had applied these profits in relief of rates.] Mr. White (continuing): It is likely, I contend, to become the rule of Parliament in dealing with these matters. In the face of a loss which he estimated at £27,600, he asked was the Vestry prepared to agree that a contract should be entered into with the Metropolitan Company? The history of electric lighting bills so far as Marylebone parish was concerned was a fiasco from beginning to end. Mr. Crook followed Mr. White, and seconded his motion. He pointed out that the committee's report advised them that unless they accepted this opportunity of acquiring the company's electric light undertaking in their district the opportunity was gone for ever, but he reminded them that they would have full opportunity 32 years hence to take over the concern lock, stock, and barrel, at a valuation of the buildings and plant according to their then condition. Mr. S. Chick, who also opposed the committee's proposal, said he could not agree with the previous speakers, who had exaggerated matters. The facts were that the Metropolitan Electric Supply Co. had spent in Marylebone £394,000, and by October, 1901, when this proposed purchase was to be completed, they would have spent about £500,000 in the parish, and the Vestry was asked to issue either 5 per cent. stock or its equivalent in value in 3 per cent. stock at the option of the company. As a member of the committee he opposed the report. He agreed with Mr. White on the question of the increase in expenditure which would be sure to follow the acquisition of the undertaking by the Vestry. In all their experience of public corporations he did not think there was a case where a public body was able to manage any concern as cheaply as a private company could do. He had another objection to the proposal, and that was that he considered it should be left to the new Borough Council. The present Vestry was an expiring body, in a few weeks they would pass out of existence, and had no right to pledge the parish to the expenditure of nearly a million of money. He hoped they would make it a test question at the forthcoming elections, and then if the ratepayers approved the committee's scheme they would have taken the matter out of the Vestry's hands, and if there was any suffering they would suffer with their eyes open. One other point required to be made. He thought if they went to the Board of Trade again they would obtain a provisional order. He was in the House of Commons when the Marylebone Electric Lighting Co.'s bill was, on the motion of Mr. Ritchie, shelved on the ground that negotiations were pending between the Vestry and the Metropolitan Company for the purchase by the former of the Marylebone section of the Metropolitan Company's undertaking. [The Chairman again interposed, and said that Mr. Chick's recollection of the parliamentary incident was wrong. Mr. Ritchie's amendment was that the bill should be passed, and if the agreement between the Vestry and the Metropolitan Company was not carried out, then the order was to be given to the Marylebone Company.] Mr. Chick (continuing) thought the chairman was right in this matter, but it came to the same thing, that no support was to be given to the passing of the Marylebone Company's bill if the Vestry purchased the undertaking of the Metropolitan Company within its district. He thought that the rejection of the Marylebone Company's bill was unfortunate, as by throwing out that bill, which was a competing bill against the Metropolitan Company, they had done themselves. If that bill had passed they would have had a lever to go to the Metropolitan Company with in the matter of greatly reducing the amount which that company asked the Vestry to pay for the purchase. Evidently, if they had applied to the Board of Trade they would have obtained a provisional order. There was, in his view, no doubt about that, and he therefore thought that if they needed it, a competing order could be obtained if they applied for it another Session. In any case they would not be prejudiced by rejecting the present proposal. Other speakers having favoured and opposed the motion, the debate was adjourned until Tuesday.

On Tuesday a special meeting of the Vestry resumed the debate on Mr. White's motion. The discussion lasted over three hours. At the close of some remarks by Sir E. Galsworthy, in opposition to the proposed purchase, a division was taken, when the non-confirmation of the minutes of Aug. 2, 1900, was carried by 31 to 26. A division was demanded and was taken, but the voting remained the same. By the non-confirmation of the minutes the scheme proposed by the Special committee has fallen through.

Matlock Bath.—An interview has been arranged between the Council and representatives of the North British Electric Supply Co., who propose to apply for a provisional order to establish electricity works in the district.

Municipal Telephony.—The Postmaster-General has granted a licence for 25 years to the Portsmouth Council to establish a municipal telephone exchange. A special committee is to be appointed to take charge of the undertaking, and the local authorities of several contiguous districts have offered their co-operation.

Oldham.—An inquiry was held on Tuesday by Mr. A. P. Trotter into the application of the Council to borrow £28,000 for electric tramways.

Paisley.—A report has been issued under instructions from the Council as to the finances of the electricity department. The cost of the new station is put at about £95,000, and the report deals in detail with the extra cost beyond the estimates. The following figures are given: Building estimate £5,500, cost £20,562; machinery and plant estimate £18,200, cost £33,277; mains for arc lamps estimate £5,050, cost £20,724; transformers and sub-station estimate £1,100, cost £9,416. The original works were designed to supply current to 10,000 8 c.p. lights, and the estimated cost was £33,750, or £65 per kw. Taking the capital expended at £95,000 and the capacity at 1,100 kw., the cost of the installation was about £86 per kw. But the extensions to mains, &c., required to take up the current still in reserve will probably make the cost from £90 to £95 per kw. The explanation, however, appears to be that a mistake has been made in putting down too much plant ahead of their needs, and that all will come right in due time. The report is to be discussed at the next Council meeting.

Patent Amendment.—The Reason Manufacturing Co., 111, Gloucester-road, Brighton, have applied for leave to amend specification of letters patent No. 5,863 of 1894 granted to Mr. Henry Reason for "Improvements in fuse boxes for electricity supply mains." Particulars of the proposed amendment are set out in the

Digitized by Google

Illustrated Official Journal (Patents) for Oct. 10, and notice of opposition must be sent in within one calendar month from that date.

Patents and Trade Marks in the Transvaal and Orange River Colonies.—Messrs. Seymour Salaman, Townroe & Co., solicitors, write us on this subject as follows:—

In view of the great influx of trade which will doubtless follow the pacification of the countries which have been formally annexed to the British possessions in South Africa, we made inquiries on behalf of intending exporters what changes had taken place with regard to patents and the registration of trade marks, and we think it may be interesting to state that all applications can now be filed with the military governor, who will grant a receipt for the documents and note particulars of the application. When the registry office is re-opened the applications can be proceeded with under the existing laws of the former States. The procedure is intended to grant to patentees the protection accorded to them in terms of the former acts, which appear still to regulate patent and trade-mark law. The same fees will have to be paid as heretofore. The forms were simple under the former procedure, and no difficulty existed in obtaining certificates in due course.

Penzance.—The Council recently advertised for a consulting electrical engineer, and at the last meeting the Electric Lighting committee reported the receipt of 28 applications. These have been reduced to eight, from which the committee will make a final selection.

Personal.—At the last meeting of the Worcester Electricity committee it was announced that the 12 months' leave of absence granted to Mr. C. J. Sutherland, the borough electrical engineer, owing to ill-health, had enabled the doctors to combat the complaint from which Mr. Sutherland was suffering, and his many friends will learn with satisfaction that the further two months' leave which he has been granted will probably suffice to quite restore him to health and strength.

Perth (Western Australia).—The second electric tramway route has been opened. There are now 9 miles of tramway in operation out of the 20 miles authorised.

Post Office Telephones in the Metropolis.—A contemporary states that a firm at the West End, wishing to obtain a Post Office telephone, applied to know the terms of the General Post Office, and received the following official answer:—"Post Office system in the City and certain other districts will be working by the beginning of 1901, but the Department fear it will be some 18 months or two years before the system can be extended to Paddington or Vauxhall. Not yet in a position to state rates, but hope to do so shortly."

Power Transmission.—La Société Electricité et Hydraulique, Charlerol, is furnishing an electric-power transmission plant at the works of the Société de Sambre et Moselle (Belgium). The plant has a capacity of 1,500 H.P., and supplies current for 80 motors and 10 cranes.

Presentations.—On Friday last the directors and London staff of the Brush Company presented their general manager (Mr. R. Percy Sellon) with a silver bowl and a silver inkstand, together with an illuminated album containing the autographs of the 80 subscribers to the gift. The occasion of the presentation, which was made at the head office, was Mr. Sellon's approaching marriage.

A presentation of plate was recently made by the staff of the Ashton-under-Lyne electricity works to the chief engineer (Mr. W. H. Vincent) on the occasion of his marriage. The presentation was made by the first assistant engineer (Mr. Bruton). It will be seen by our "Appointments" notes that Mr. Vincent is about to proceed to Bermondsey (London) to take up a new appointment there.

Ripon.—A provisional order will be applied for by the City Council. The consulting engineers are Messrs. G. Harrison & Co.

Rochester.—Negotiations are in progress between the Council and the Chatham, Rochester, and District Electric Light Co. regarding the purchase of the company's undertaking in Rochester.

St. George's Hanover-Square (London).—A special meeting of the Vestry was held last week to receive a report from the Electric Lighting committee in regard to the electric lighting of the streets. At the outset a communication was read from the Gas Light and Coke Co. asking the Vestry to postpone their final decision, as the company had under consideration a more comprehensive scheme for the better gas lighting of the parish at much less cost than the scheme for electric lighting. Notwithstanding this the committee recommended that the agreement with the Westminster Electric Supply Corporation be approved and adopted, and that the seal of the Vestry be affixed. The agreement provided that the company should commence the works immediately, and should complete the work of erecting 600 arc lamps by June 30, 1902. Lighting according to schedule was to be at the rate of £32 per annum for each 750 watt and £22 for each 500 watt arc, £4 per annum for each 120 watt and £3 for each 60 watt incandescent lamp, these rates to be subject to a cumulative rebate of ½ per cent. per annum for each year after the first full year during which any lamp had been used. A clause provided that in the tenth and twentieth year after the date of the agreement the Vestry should be entitled to refer to an arbitrator the question whether the charge should be varied in consequence of the adoption by the company of any improvement or method which had resulted in a substantial alteration in the cost of public electric lighting, with power to the arbitrator to vary the payment, but no variation should be made which should cause the future profits of the company to be less then they were immediately prior to the adoption of such improvement or method. If, however, any increase in profit should result from the adoption of such improvement or method, the increased profit might be apportioned between the company and the Vestry in such manner as the arbitrator should think fit to award, but the award is not to be retrospective. Mr. ANTROBUS moved that the committee's report be received. The letter of the Gas Company did not commend itself to him. Full consideration had been given to the vast question of lighting the parish, and he thought that the Gas Company's letter asking them to postpone the consideration for two years on such a flimsy and out-of-date application was out of all reason. The Westminster Corporation had met them on two points, and this induced the committee to make their present recommendation. The first point was in regard to arc lamps and posts. The committee considered that those should be part of the capital outlay the company would have to expend, but the company thought otherwise. The company eventually conceded this, so that the cost of the lamps would not be an additional item, but would be included in the tender. The other objection raised was the duration of the agreement. The way in which the committee proposed to meet it was that at the end of 7, 14, and 21 years there should be, on the part of the Vestry, the right of calling in an arbitrator to have the terms altered. The company objected strongly at first, but finally they agreed to give the right of revision at 10 and 20 years. Mr. TASKER moved an amendment that the matter be referred to the new municipality. Mr. EVERITT said the matter of lighting the parish had been before the Vestry for 14 years. The new Council would not be able for 31 years to supply private consumers, and they could not make it pay if they had a municipal supply for street lighting only. At the termination of the agreement the Corporation would be able to embark on a scheme of their own for both public and private lighting. The amendment was defeated by 32 to 28.

After further discussion the seal of the Board was affixed to the agreement.

Singapore.—This city boasts a considerable German community, which has recently erected an extensive club building to replace the old "Teutonia" Club, and chiefly for the lighting of this club there has been put down an electric lighting installation far in advance of anything of the kind previously known in Singapore. The work has been carried out by Messrs. Howarth Erskine (Ltd.), under the direct supervision of Mr. G. E. V. Thomas. There are in all 270 incandescents of 32 and 16 c.p., besides several arc lamps; 63 of the 32 c.p. lamps are placed in the roof of the assembly rooms, and the light is filtered through panels of silk with striking effect. The Teutonia Club installation is of some general importance, as it forms the nucleus of a small supply station for neighbouring residences, some of which are already connected up. The club house is a semi-public building, and is supplied with current from plant erected in an outside station, and paid for by meterage, the charge being 50 cents. (1s.) for the first 300 kilowatt-hours per mensem and 40 cents. (10½d.) after. These charges appear heavy, but it must be remembered that the wretched gas at Singapore costs 8s. per 1,000 cubic ft.

Smethwick.—Negotiations are proceeding between the British Electric Traction Co. and the Corporation in regard to electric tramways and the supply of electricity in the district. The Council have called in Mr. J. G. Aldridge as their consultant, and he will report upon the advisability of accepting the company's terms, which include powers to the Council to take over the concern in 7 or 14 years after the expiration of the present lease, the company paying all expenses of management, and handing to the Council a percentage of the gross receipts, and also undertaking to supply electricity for lighting and other purposes to private consumers at the rates current in neighbouring districts.

Southampton.—At the last meeting of the Corporation a notification was received that it had been decided that the machines in use at the Ordnance Office were gradually to be adapted for electric driving, and that the question whether to generate their own electricity or to take it from the Corporation was under consideration. The Corporation are asked to state at what price they will supply current for power, and whether current for power would, like that for lighting, be alternating; also, whether the Corporation would, in the case of the department, make a reduction in the present price of 6d. per unit for lighting. The subject is being considered by a committee.

Mr. Smith has resigned his position as mains superintendent.

Southport.—The salary of the electrical engineer (Mr. C. D. Taite) has been advanced to £400 per annum, increasing to £600 by annual increments of £50.

Sunderland.—The Council have applied for sanction to borrow £73,035 for the erection of a new electricity station at Hylton-road to

Digitized by Google

the plans of the electrical engineer (Mr. J. F. C. Snell). A very complete report has been prepared by Mr. Snell, in which it is stated that the capacity of the Dunning-street station will not permit of further extensions after next year. In 1898-9 the total units of current supplied by the Corporation were 472,343, and in 1899-1900 640,079. For the next three years Mr. Snell estimates the figures to be as follows: 1,026,740, 1,730,000, and 1,919,000. From Jan. 1 electric light consumers will have the option of being charged on the present maximum demand system or at a uniform rate of 5d. per unit. A reduction of meter rents, to date from Oct. 1, has been approved.

Stratford-on-Avon.—Opposition is to be offered by the Council to the application of the Union Electric Light and Traction Co. for a provisional order.

Taunton.—The agreement with the National Electric Wiring Co. has been terminated. During the past quarter the equivalent of 410 8 c.p. lamps were connected to the mains.

Telegraph Regulations.—The Postmaster-General gives notice that regulations have been made in pursuance of the Telegraph Acts, 1863 to 1899, relating to foreign-written telegrams.

Telephone in Manchester.—A conference of local authorities was held last week at Salford to discuss the question of providing an improved telephone service within the Manchester area of the National Telephone Co. The Mayor of Salford presided, and there also attended Ald. Holland (chairman of the Salford Telephone committee) and other members of the Corporation, and about 30 representatives of neighbouring authorities. Ald. Holland said the Salford Corporation had no cut-and-dried programme to propose for acceptance, but desired to hear the views of the authorities comprised within the Manchester area, so that there might be a consensus of opinion in regard to the ultimate steps to be taken to secure the end in view. Salford did not, in taking the initiative, seek any position of precedence, and whether the improvement was to be effected by the municipalisation of the telephonic system or by the formation of a new competing company was entirely a question to be decided after general consideration of the subject by those interested. After a long discussion, a resolution was approved appointing a committee to consider the question and to report their recommendations to a future meeting. It was decided that the committee should consist of one representative from each of the local authorities invited to the conference, including Salford, Eccles, Bowdon, Failsworth, Prestwich, Levenshulme, Swinton and Pendlebury, Whitefield, &c.

Telephone Trunk Extensions.—Trunk line telephone communication has been extended to Bishop Stortford.

Tiverton.—The Lighting committee have not yet been able to meet the objections of the Board of Trade in regard to the construction of a weir across the river, which formed a part of the electric lighting scheme of the consulting engineer (Mr. W. P. Adams). The Council are, however, recommended to authorise the immediate prosecution of scheme.

Trade Unionism Run Mad.—It is not unusual in the printing trade to put machine-room labourers to many kinds of miscellaneous work. Amongst the odd jobs performed by some of these men is the cleaning of the windows of the machine-rooms in which they are employed. Amongst employers there is a difference of opinion as to whether this is the sort of work a labourer should be called upon to perform, and it is not, therefore, surprising that some of the better class of labourers decline to clean windows. In one of the large printing offices in London the labourers have gone a step further, and have insisted that all the windows of the establishment shall be cleaned by the Window Cleaners' Society! If this claim is admitted it is not unlikely employers of labour will be instructed to place their laundry work in none but trade union hands. In fact, the idea admits of indefinite extension, and may be considered a step in advance towards Collectivism.

Vienna.—A large lighting and power transmission plant has been installed at the engineering works of the Austro-Hungarian State Railway Co. by Messrs. Ganz & Co. The plant supplies current for 40 arcs and 200 incandescents, and also for 40 motors ranging from ½ H.P. to 30 H.P.

Walsall.—Sanction to a loan of £9,470, out of £15,000 applied for, has been obtained by the Council. Details of a loan of £5,678 for the extension of the electric lighting mains to Bescot are to be submitted.

Westminster (London).—The question of petitioning the Board of Trade to hold an inquiry into the charge made for electric current by the Westminster Electric Supply Corporation was raised at last week's Vestry meeting. The committee to which the question was referred reported they were of opinion that the section of the public now concerned in the matter was not sufficiently numerous to justify the Vestry in taking further action in the matter. An amendment was, however, proposed that a communication should be sent to the Board of Trade urging the importance of holding an inquiry with a view to bring about a reduction in the price, and this was carried by 21 votes to 10.

Wigan.—The Tramways committee have applied to the Councils of Standish and Aspull for sanction to construct electric tramways in those districts. The Wigan Corporation recently offered to give a supply of electric current for lighting in various adjoining districts, including Aspull, Standish, Pemberton and Ince-in-Makerfield, but these local authorities have decided to apply for provisional electric lighting orders and independent works will probably be erected.

Wireless Telegraphy.—The Southend Council have given permission to the Signals Syndicate to give demonstrations from the pier of their system of wireless telegraphy in signalling to vessels at sea, &c.

Worcester.—The City Council have now decided to acquire the Tybridge-street site for a new electricity station for £4,450. The electrical engineer (Mr. C. J. Sutherland), whose 12 months' leave of absence, granted in consequence of ill-health, has now expired, is to be granted a further two months' leave to complete a cure, which, we are glad to learn, the doctors certify is already practically complete.

Wycombe.—The Council have approved the scheme for the construction of electric tramways, and parliamentary powers are to be applied for.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.

Swansea Corporation require tenders for electricity meters, demand indicators and main fuses. An advertisement gives further particulars, and specifications may be obtained after 22nd inst. at the Guildhall, Swansea. Specifications may also be inspected (but not obtained) at the offices of the consulting engineers (Messrs. Kincaid, Waller and Manville), 29, Great George-street, Westminster. Tenders must be sent to the town clerk (Mr. Jno. Thomas) before noon of 29th inst.

Lowestoft Corporation invite tenders for the supply of two water-tube boilers, fittings, economiser, &c.; pipework, &c., in engine and boiler house; and a 250kw. steam dynamo (vertical, enclosed, high-speed engine). An advertisement gives further particulars, and specifications may be obtained from the town clerk (Mr. R. Beattie Nicholson), 115, High-street, Lowestoft, after 20th inst. The works are to be carried out in accordance with the plans of the consulting engineer (Mr. W. C. C. Hawtayne), 9, Queen-street-place, London, E.C. Tenders to town clerk's office by noon of Nov. 2.

Lowestoft Corporation also invite tenders for wiring the town hall. An advertisement gives further particulars, and tenders must be delivered at the offices of Mr. R. Beattie Nicholson before noon on Nov. 2.

Bradford Corporation invite tenders for a 30-ton electric travelling crane for their Valley-road electricity works. An advertisement gives further particulars, and specifications may be obtained from the city electrical engineer (Mr. R. A. Chattock). Tenders to town clerk (Mr. Frederick Stevens), Town Hall, Bradford, before 25th inst.

Heywood Corporation invite tenders for wiring premises in the district. Copies of regulations may be obtained from the consulting engineer (Mr. W. P. Adams), 35, Queen Victoria-street, London, E.C., and tenders must be sent to the town clerk (Mr. J. H. Baldwick). See advertisement.

Belfast Gas and Electric Light committee invite tenders for steam pipes, pumps, &c., condensing plant, boilers, mechanical stokers and superheaters, coal and ash-conveying plant and switchboard extensions. Tenders to town clerk (Sir Samuel Black) by noon Nov. 23.

The Streets committee of *City of London* Corporation are again inviting tenders for a mechanically-driven dust cart. Tenders to town clerk (Sir J. B. Monckton) before Nov. 10.

The *Postmaster-General* is inviting tenders until 22nd inst. for red fir telegraph poles and for creosoting. Forms of tenders from Mr. Chas. E. Stuart, controller of stores, General Post Office, London.

London County Council require tenders for 12 months' supply of engineers' goods and electrical stores. Tenders to clerk, County Hall, Spring-gardens, S.W., by 29th inst.

Strand (London) District Board of Works invite tenders for a steam dynamo, switchboard, &c., for their destructor works at Lambeth. Tenders to 5, Tavistock-street, W.C., by 24th inst.

Whitechapel (London) Electrical committee require tenders for a hand-driven overhead travelling crane for their electricity station. Tenders to chairman must be delivered by noon 23rd inst.

Cardiff County Borough invites tenders for slow-speed vertical engines, slow-speed converters, and boilers and economisers, &c. Tenders to Town Clerk by 23rd inst.

Digitized by Google

The Council of the *Glasgow International Exhibition*, 1901, require tenders for wiring for arc and incandescent lamps and electric motors. Particulars from 4, West Regent-street, Glasgow.

Partick Burgh Commissioners invite tenders for the erection of an electricity station and refuse destructor buildings. Tenders by 29th inst.

Grimsby Corporation invite tenders for a refuse destructor. Tenders by Nov. 6.

Grantown-on-Spey Burgh Commissioners invite tenders for electric lighting. Tenders by Nov. 6.

TENDERS RECEIVED AND ACCEPTED.

Bermondsey (London) Vestry have referred to their Electric Lighting committee the following tenders :—

Steam, Feed, and Exhaust Pipes, Feed Pumps, &c.

G. Hopkins & Sons	£5,673 0 0
Alley and Maclellan	4,500 0 0
Babcock and Wilcox	3,483 0 0
Crompton & Co.	£3,292 and 3,023 0 0
John Spencer (Ltd.)	2,672 10 0
Thos. Horton & Co.	2,006 10 0

Steam Dynamos, Belting, Charging Motor, Booster, and Balancer.

Siemens Bros. & Co.	£5,447
British Westinghouse Co.	£5,409, £5,000, and 5,109
Electric Construction Co.	4,942
D. Bruce Peebles & Co.	£4,924, £5,024, £4,768, and 4,764
Crompton & Co.	4,906
Mather and Platt	£4,840, £4,830, £4,760, and 4,400
E. J. Macdonald	4,788
E. Scott and Mountain	4,495
Bergtheil and Young	4,113
Thames Ironworks Co.	3,835

Brighton Town Council received the following tenders for (1) 2,000 tons of steel girder tramway rails (including curve rails), 78 tons of steel fishplates, and 90 tons of steel joists :—

Bolckow, Vaughan & Co. (*accepted*)	£18,397 0	Barrow Hematite Co.	£18,564 0
William David	19,700 0	Westfalisch Stahlwerke	16,975 18
Leeds Steel Works	18,970 0	Witting Bros.	16,941 13
R. White & Sons	18,564 10	Edward Le Bas & Co.	15,718 0

Only Nos. 1 and 2 complied strictly with the specification.

(2) For motor cars (for 57 passengers) :—

*British Westinghouse..each	£630 0	‡Hurst, Nelson & Co. each	£440 0 0
Witting Bros. ,,	765 0	†Queen's Dock Electrical Works ,,	435 0 0
Brush Co. ,,	728 0	†Siemens Bros. & Co. ,,	340 0 0
Dick, Kerr & Co. ,,	724 0	§Geo. F. Milnes & Co. ,,	295 0 0
‡Gottfried Lindner ,,	710 0	‖R. W. Blackwell & Co. ,,	72 1 9
British Schuckert Co. ,,	685 0	‖Loraine Steel Co. ,,	63 0 0
British Thomson-Houston Co. ,,	647 17	‖F. Nell ,,	55 16 0

* *Accepted* for 25 cars, total £15,750. † Electrical equipment only. ‡ Bodies and trucks only. § Bodies only. ‖ Trucks only.

London County Council has accepted the following tenders for supply of lamps, &c., for the electric light installation on the Victoria Embankment and Westminster Bridge :—

	5 lamps in series (enclosed arcs).	10 lamps in series (open arcs).
St. Helens Cable Co (*accepted*)	£5,016 5 0	£4,300 0 0
Western Electric Co.	8,429 12 0	7,582 3 6
W. T. Henley's Co.	6,288 1 10	5,552 5 10
British Insulated Wire Co.	5,786 16 10	5,013 1 8
Siemens Bros. & Co.	5,762 12 6	4,947 17 6

Tenders and designs were recently invited by the consulting engineers (Messrs. O'Gorman and Cozens-Hardy) for 16 large electroliers for Bridgewater House, the town residence of the Earl of Ellesmere. The work has been given to Messrs. Donnison, Berlyn, Sillem & Co. at £1,030, the large cut-glass bowls forming part of the electroliers being by Messrs. F. and C. Osler.

The contract for the electric lighting and power distributing plant at the Free Wall Paper Co., Louth (Lincs.), has been placed with Messrs. Crowther & Co., of Manchaster.

Southampton Harbour Board have accepted the tender of the Clayton Engineering and Electrical Construction Co. for the supply of an electrical travelling crane at £785.

The tender of Messrs. G. N. C. Mann & Co. has been accepted for the electric lighting of the Suffolk County Asylum, Melton, at £3,000.

Middleton Corporation have accepted the tender of Messrs. R. Partington & Son for the erection of electricity station buildings.

APPOINTMENTS VACANT AND FILLED.

A mechanical engineering assistant is required for the office of a municipal engineer of a large town in the Midlands. Candidates must have had experience in electric tramway construction and steam practice. Applications by 26th inst. See advertisement.

A new accumulator company requires an electrical engineer with experience of accumulator traction. Applications to Messrs. O'Gorman and Cozens-Hardy, consulting engineers, 82, Victoria-street, Westminster. See advertisement.

An assistant is required in the meter-testing department of the Edinburgh electricity works. Applications to resident electrical engineer (Mr. F. A. Newington). See advertisement.

Worthing Council require a borough electrical engineer. Applications by 25th inst.

Bray (Ireland) Council will on 22nd inst., elect a resident electrical engineer. Applications to clerk.

Mr. W. H. Vincent, borough elctrical engineer, Ashton-under-Lyne, has been appointed resident electrical engineer to the Bermondsey (London) Vestry. There was no less than 46 applications, and five of the candidates were interviewed by the Vestry on Monday. Mr. Vincent served his articles with Messrs. James Simpson & Co., Pimlico, and subsequently entered the service of the Scottish Oriental Steamship Co. as marine engineer. In 1891 he was engaged on the staff of the Metropolitan Electric Supply Co ; in 1892 entered the service of Messrs. Siemens Bros. & Co. ; and in November, 1898, he was appointed borough electrical engineer at Ashton-under-Lyne.

Mr. G. H. P. Morgan has been appointed assistant engineer at Belfast.

BUSINESS NOTICES.

The Direct United States Cable Co.'s branch station at South Sea House, Threadneedle-street, London, E.C. (adjoining the Baltic) has been removed to 4, Bishopsgate-street Within, E.C , and a station has also been established at 142A, Winchester House, Old Broad-street, E.C.

We are asked to state that Mr. Ernest J. Pond, who was lately with the Telegraph Manufacturing Co. (Ltd.) as London traveller, has joined the staff of Henley's Telegraph Works Co. (Ltd.) as country traveller.

BANKRUPTCIES, LIQUIDATIONS, &c.

A receiving order has been made against Cornelius Bennett Harness, 20, Macaulay-road, Clapham, late managing director of the Medical Electrical Institute (Ltd.). 52, Oxford-street, London.

A supplementary dividend of ½d. will be payable on 23rd inst. at the office of the trustee (Mr. E. H. Hawkins), 3, Barbican, London, E.C., in the bankruptcy of A. G. Inrig (lately trading as the Globe Electrical Co.), 46, White Post-lane, London, E.

A meeting of the Sussmann Electric Miners' Lamp Co. (Ltd.) (in liquidation) will be held at 10, Walbrook, London, E.C., on Dec. 1, to receive an account of the winding-up. Mr. R. Warner is liquidator.

Creditors of the Aluminium Co., Ltd. (in voluntary liquidation), must send particulars of claims to liquidator (Mr. P. L. Court), 13, Abchurch-lane, London, E.C., before Nov. 5.

Claims against the Printing Telegraph Recorder Co. (Ltd.) must be sent by Nov. 15 to the liquidator (Mr. G. A. G. Robertson), 13, Basinghall-street, London, E.C.

Winding-up Petition.—A petition for the winding-up of the Coventry Gas Fitting, Electrical and Engineering Co. (Ltd.) has been presented, and will be heard on 24th inst. A receiver and manager on behalf of the debenture holders was appointed by the vacation judge (Mr. Justice Buckley) on Wednesday.

Sales by Auction.—Particulars, plans, and conditions of sale are now ready of the sale by auction, by Messrs. Wheatley Kirk, Price & Co., at the Mart, Tokenhouse-yard, London, E.C., on Friday, 26th inst., at 12:30 for 1 o'clock prompt, of the long leasehold works of the Ormonde Cycle Co. (in liquidation), at Hornchurch-road, Romford, Essex, together with motive power, fixtures, erections, &c. There is also for disposal the goodwill, contracts, and trade marks of the Ormonde Company, together with valuable leasehold premises at Wells-street, Oxford-street, London, W., the whole as a going concern. Catalogues can be had of the auctioneers, 49, Queen Victoria-street, London, E.C., and Albert-square, Manchester, who will furnish all further particulars.

Messrs. Fuller, Horsey, Sons and Cassell, 11, Billeter-square, London, E.C., will sell by auction on the premises, Tower House, Chiswick-lane, Chiswick, Middlesex, on Wednesday, Nov. 7, at 11 o'clock precisely, a small electric generating plant, particulars of which are set out in an advertisement elsewhere.

Plant for Sale.—Leeds Lighting committee invite tenders for the purchase of rope-driven electric generating plant about to be replaced by plant of larger capacity. Particulars are given in an advertisement, and conditions, &c., may be obtained from the manager of the Electric Lighting Department (Mr. H. Dickinson), 1, Whitehall-road, Leeds. Tenders, addressed to town clerk (Mr. W. J. Jeeves), by Nov. 18.

Oldham Electric Light committee invite offers for lead battery boxes, plates, and copper connections. An advertisement gives some further particulars, and offers are to be sent to the superintendent (Mr. Arthur Andrew), Gas and Water Offices, Oldham, by Nov. 4.

Paris Exhibition Souvenir.—The literature of the Paris International Exhibition, 1900, has been somewhat meagre, making

Digitized by Google

all the more welcome a handsome souvenir sent out by Messrs. Witting Bros. (Ltd.), of 49, Cannon-street, London, E.C., in which opportunity is taken to illustrate a number of the machines exhibited at Paris by the Charleroi and London branches of the firm. The souvenir is in the form of an album, and contains some good views of many of the principal architectural features of the Paris show.

"Ediswan" Electrical Apparatus and Accessories.—For many years past the Edison and Swan Co. have made a prominent feature of their sectional catalogues of electrical apparatus, and

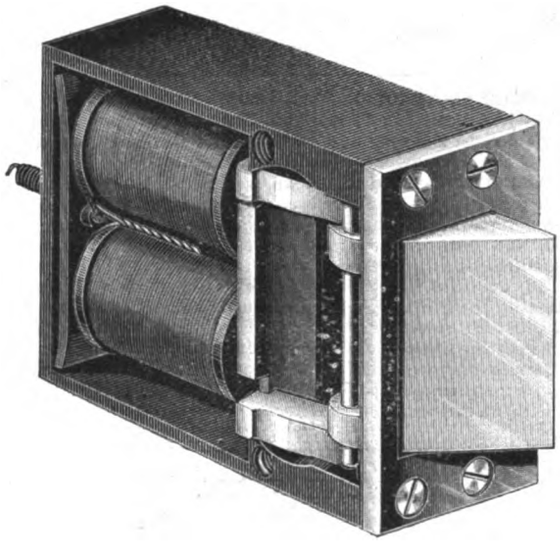

FIG. 1.

especially of those sections dealing with electric bell and indicator work, fire-alarm movements, instruments, and electrical sundries. We have now to acknowledge the receipt of Section 12 of the main catalogue, and below we illustrate and describe a few of the latest forms of "Ediswan" specialities. Fig. 1 shows an electric latch, with projecting nosing for releasing heavy weights.

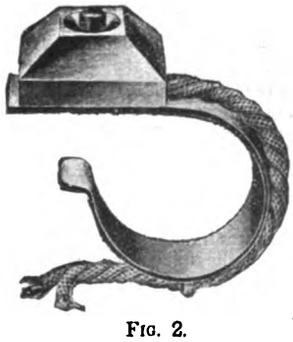

FIG. 2.

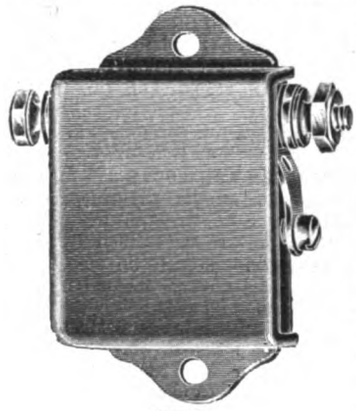

FIG. 3.

Switching on current causes the armature of the electromagnet to be attracted, releasing a catch, and the latch is instantly pushed on one side by the weight it has been supporting. Fig. 2 shows a useful form of bell push with spring clip for fixing to table or other projection. Fig. 3 shows a metal frame electric buzzer for use where a sharp ring of an ordinary bell would be objectionable. This

FIG. 4.

buzzer has platinised contact points. The section on pushes illustrates these goods in infinite variety. Fig. 4 is a midget metal push which fits into a ⅜in. hole and is provided with spring clips which hold it securely in place. We have room to illustrate a few only of the examples of which the catalogue contains a large number. Crowded with excellent illustrations, it is a credit to its compilers, and the printing is in the usual excellent style of the "Ediswan" catalogues. To the supplies dealer this publication must be as useful as it is interesting.

"Brockie-Pell" Arc Lamps at Poplar.—The Brockie-Pell Arc Lamp (Ltd.) inform us that the whole of the arc lamps supplied to the Poplar electricity works, which were opened last week, were of their patent Brockie-Pell type and manufactured by them under the patents of which they are the sole owners.

Auer Electric Lamp.—At a meeting of the Welsbach Incandescent Gas Light Co. on Wednesday, it was announced that Dr. Auer's new electric lamp had been installed that day in the Austrian pavilion of the Paris Exhibition, and was now on view there. The lamp is said to have been tested by the Emperor of Austria, with the result that His Majesty has given orders for the lamp to be installed in all his palaces throughout Austria.

"Papristeel" Conduit.—The General Electric Co. (Ltd.) forward a circular describing an improved form of "Union" steel tubing, for which it is claimed that to the mechanical advantages of this material have now been added good insulation and damp proofness. The tubing can be supplied with screwed fittings, standardised to use with the company's "Union" system of accessories. "Papristeel" conduit is manufactured of paper tube drawn over with the "Union" steel conduit, the whole being enamelled inside and out and stoved together.

Plant Price List.—Messrs. J. P. Hall & Co., of Oldham, have just issued a new price list of dynamos, motors, &c.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from Oct. 10 to Oct. 16, with the ports of destination :—

Africa.—Cape Town, £317; Durban, £280; East London, £61; Port Elizabeth, £222. *Argentina*—Buenos Ayres, £200 (telegraph material). *Australasia*—Auckland, £178; Fremantle, £944; Launceston, £138; Melbourne, £176; Otago, £305; Perth, £138; Sydney, £2,353 (including £614 telegraph material); Wellington, £125. *Belgium*—Ostend, £219. *Canada*—Halifax (N.S.), £29 (telegraph material); Vancouver (B.C.), £19. *Ceylon*—Colombo, £239. *China*—Newchang, £11; Shanghai, £16. *Germany*—Hamburg, £260 (including £200 telegraph material). *Holland*—Amsterdam, £64; Rotterdam, £55 (including £45 telegraph material). *Hong Kong*, £201. *India*—Bombay, £234; Calcutta, £2,423; Madras, £108. *Japan*—Hiogo, £48; Nagasaki, £6,602 (telegraph cable); Yokohama, £7,057 (including £4,586 telegraph material). *Malta*, £452 (including £302 telegraph apparatus). *Russia*—St. Petersburg, £225 (telegraph material). *Seychelles*, £11 (telegraph instruments). *Straits Settlements*—Penang, £138 (telegraph material); Singapore, £60. Total £23,908, against £340,335 in the corresponding week last year (Oct. 11 to Oct. 17).

PATENT RECORD.

The following list of Applications for Patents and Specifications published has been compiled for this journal by MESSRS. J. C. CHAPMAN and Co., *Chartered Patent Agents, of 70, Chancery-lane, W.C., from whom any available information in connection with Patents, Designs, and Trade Marks may be obtained.*

APPLICATIONS FOR PATENTS.

September 4, 1900.

15,748. G. W. PARTRIDGE. London. Improvements in or relating to electric switches, fuses and other apparatus in which destructive electric arcs are liable to be formed.

15,752. H. HIRST and G. H. IDE. London. Improvements in and relating to electroliers, pendants and fittings, or connections therefor.

September 5, 1900.

15,774. W. CLAR. London. An improved electrical signalling apparatus for fire alarms and other purposes.*

15,793. H. GULLIVER and T. C. FOWLER. London. Improved electric travelling contact appliances for establishing telephonic and signal communication on railways between the signalman in the box and the driver of a locomotive.

15,818. H. M. HOZIER, C.B., and A. W. SHARMAN. London. Improvements in and relating to electrical signalling apparatus.

September 6, 1900.

15,864. W. C. C. HAWTAYNE. London. Improvements in and relating to street lamp fittings for incandescence electric lamps.

15,865. W. E. LANGDON. London. Improvements in shades for electrical and other lamps.

15,870. T. J. RICALDONI. London. Improvements in apparatus for producing electric waves.*

15,872. J. LENDERYOU and T. S. M. WYATT. London. Improvements in arc lamps.

15,878. A. VANDAM and G. C. PILLINGER. London. Improvements in fuse boxes and fuse boards.

15,888. J. C. FELL. London. Improvements in electric meters. (W. Stanley, United States.)*

September 7, 1900.

15,890. S. BEETON and M. BARR. Cheshire. Improvements in electric cable connections.

Digitized by Google

15,907. F. Booker. Shepherd's Bush. Improvements in electric arc lamps.
15,918. The British Thomson-Houston Co. (Ltd.). London. Improvements in electrical phase transformation. (A. D. Lunt, United States.)*
15,919. The British Thomson-Houston Co. (Ltd.). London. Improvements in electric rotary transforming apparatus. (A. G. Davis, United States.)*

SPECIFICATIONS PUBLISHED.

Note.—All Specifications can now be obtained at the uniform price of 8d. each.

1899.

14,304. Thompson (Cantono). Application of electric motors for automobile vehicles.
17,274. Needham. Process of galvanizing iron.
17,445. Heyl-Dia. Electric cables.
17,722. Crehore and Squier. Telegraphic apparatus.
17,786. Brown. Electric telegraph apparatus.
18,005. Lucas and New. Secondary galvanic batteries or accumulators.
18,468. Chamberlain and Hookham (Ltd.) and Holden. Electricity meters.
18,547. Wilson. Continuous-current electric motors or generators of enclosed type.
18,754. Meyer. Galvanic batteries.
18,759. Fowler and Reason Manufacturing Co. (Ltd.). Disconnecting boxes for electric cables.

COMPANIES' MEETINGS AND REPORTS.

Cuba Submarine Telegraph Co. (Ltd.).

The report of the directors of this company for the half-year to June 30, states that the total receipts amounted to £15,336. 1s. 6d., and gross expenditure to £6,296. 13s. 5d., leaving £9,039. 8s. 1d., which, with £5,165. 7s. 3d. brought forward leaves £14,204. 15s. 4d. to credit of revenue. The traffic receipts show a large decrease compared with the corresponding period of last year, due to competition and the bad state of business in the West Indies and Cuba. £2,000 has been added to reserve, which now stands at £132,000. The dividend on the preference shares absorbs £3,000, leaving £9,204. 15s. 4d., out of which the directors recommend a dividend at the rate of 5 per cent. per annum on the ordinary shares, free of tax, £5,204. 15s. 4d., being carried forward.

The company's cables have continued in good working order throughout the half-year.

The negotiations between the Foreign Office and the Government of the United States in reference to payment of the subsidy of £2,000 per annum, and the claim for damage done to the cables during the Spanish-American war are still proceeding. The subsidy was paid by the Spanish Government to Dec. 31, 1898, but since that date no payment has been received.

Consolidated Telephone Construction and Manufacturing Co. (Ltd.).

The directors' report for the year ended March 31 states that it was not until the end of October, 1899, that the new board of directors were in a position to complete arrangements for re-organising the management both in London and Coventry. The results for the five months immediately following that date, and ended March 31 last, were very satisfactory compared with the preceding seven months, the sales for the first-mentioned period showing an increase of over 56 per cent. above those for the corresponding months of the previous year. The steady increase in the business during the 12 months ended Sept. 30, 1900, justifies the opinion regarding the prospects of the company which the new board held when they undertook the direction of affairs. The assets of the company have been revalued where necessary. The trading profit for the year amounts to £1,192. 0s. 9d. (almost the whole of which was made during the last five months) and the total credits to revenue amount to £9,703. 13s. 9d. Deducting expenses (£2,386. 8s. 2d.) and including amount from last year (£185. 2s. 2d.), there remains after writing off £4,334. 8s. 4d. on depreciation account, a balance credit to profit and loss of £3,167. 19s. 5d. The average dividend paid during the last seven years (1893-1899) was, the report states, £1. 12s. 10d. per cent., and taking into consideration the conditions under which the year's trading has been carried on, the directors do not feel justified in recommending the payment of a dividend for the year ended March 31 last, but consider that the present position of the company justifies the payment of an interim dividend at the rate of 3 per cent. per annum for the first six months of the current financial year, and they propose to pay such dividend. The directors have reason to expect that, in the near future, this rate of distribution will be increased.

Satisfactory arrangements have been effected with several of those railway companies with whom the company had not been able for some years past to do business, and many new accounts have been opened. The friction which for several years existed between the company and the National Telephone Co. has been removed, the result being that orders have been received from that company which there is every reason to believe will be increased in the future. Considerable orders have also been received from the War Office and other Government departments, and arrangements have been made for developing the company's business in South Africa and the colonies generally. The business of the Anglo-Portuguese Telephone Co. has shown considerable expansion, and the directors believe that the position of that company can shortly be placed on a still more satisfactory basis, with consequent benefit to the Consolidated Company. The law-suit initiated by the Edison Gower-Bell Telephone Co. against manufacturers in Belgium who had infringed that company's patents has made satisfactory progress, and has entered upon its final stage, the appeal of the defendants having been decided against them.

Mr. Henry Grëwing resigned his position as a director in April last, and on the advice of Sir William Preece, Mr. C. H. Reynolds, C.I.E., late director-general of telegraphs to the Indian Government, was elected to the vacancy.

Accompanying the report is a circular issued to the shareholders opposing the election to the board of Col. Gouraud, who has given notice of his intention to offer himself as a candidate at the meeting of shareholders on 24th inst.

NEW GENERAL TRACTION CO. (LTD.)—The chairman's half-yearly report has just been issued, and deals with the present position of the company's various undertakings—viz: The Norwich and Coventry electric tramways, the Philadelphia Suburban Traction Co., and the Douglas (Isle of Man) tramways, in all of which the company has a large controlling interest, and which have been constructed and equipped under the company's direction. The Norwich lines were opened for traffic on July 30, and have since worked most successfully, producing results beyond anticipations. In Coventry the tramway was finished and opened on Jan. 18, and the directors anticipate getting a fair return on their investment. The Philadelphia Suburban Traction Co. will own tramway lines of about 20 miles, connecting Philadelphia with Chester and Media. These are nearing completion, and since July 1 a portion of the system has been in successful operation. The Douglas Southern line has been in operation some time, and the board expect the same dividend as last year (6 per cent.) on the preference shares.

CITY NOTES.

MEMORANDA.—Bank rate 4 per cent. (since July 19, 1900). Price of silver 29¼d. per oz. (Oct. 18). Consols (2¾ per cent.) 98⅞—98⅞ for money, 98 1/16—98 3/16 for account; 2½ per cent. 97½—97⅝ (Oct. 18). Stocks and Shares Continuation Days, Oct. 24 and Nov. 11; Ticket Days, Oct. 25 and Nov. 13; Pay Days, Oct. 26 and Nov. 14; Mining Share Carry-over Days, Oct. 23 and Nov. 10.

CALLENDER'S CABLE AND CONSTRUCTION CO. (LTD.)—The directors have decided to pay an interim dividend at the rate of 10 per cent. per annum on Nov. 1.

CITY OF LONDON ELECTRIC LIGHTING CO. (LTD.)—During the week this company has invited applications for an issue of £200,000 4½ per cent. second debenture stock at par.

EASTERN TELEGRAPH CO. (LTD.)—This company announce payment, on Nov. 1, of interest for the half-year ending 31st inst. on their 4 per cent. mortgage debenture stock. The transfer books will be closed from 26th inst. to Nov. 1, inclusive.

EASTERN AND SOUTH AFRICAN TELEGRAPH CO. (LTD.)—This company announce the payment, on Nov. 1, of interest on the 4 per cent. Mauritius Subsidy debentures. The transfer books will be closed from the 26th inst. to Nov. 1 inclusive.

GENERAL ELECTRIC CO. (1900) (LTD.)—In reference to the prospectus of this company commented upon in our columns last week we have received the following:—

TO THE EDITOR OF THE ELECTRICIAN.

Sir: We notice in your comment on the public issue of our company in your paper dated 12th, the remark that no mention is made in our prospectus of the Incandescent Electric Light Co. (Ltd.) We wish to reply that at the time this company was started, we thought it wise to interest one or two friends of the technical manager, Mr. Robertson, in the matter, necessitating thus a formation of a separate company, in which it is true we hold a managing control, as well as the principal amount of the capital. You will understand that for that reason the lamp factory cannot be enumerated in the prospectus as property of the General Electric Co., but it figures as the principal item of the amount of investments stated in the prospectus.—Yours, &c., H. Hirst.

We learned on inquiry yesterday that the issue this week of this company's shares and debentures has been "an unqualified success, and has been largely over-subscribed."

INDO-EUROPEAN TELEGRAPH CO. (LTD.)—An interim dividend has been declared for the half-year ended June 30 at the rate of 5 per cent per annum, free of tax, payable on and after Nov. 1. The transfer books will be closed from 16th inst. to 31st inst. inclusive.

ST. JAMES' AND PALL MALL ELECTRIC LIGHT CO. (LTD.)—The amount of electricity sold by this company for the quarter ended Michaelmas, is returned at 888,883 units, estimated to produce £15,852, against 734,763 units, which produced £13,256, for the corresponding period last year.

STOCK EXCHANGE NOTICES.—Wednesday, Oct. 31, has been appointed a special settling day in the further issue of 23,361 5 per cent. cumulative £5 (£3. 10s. paid) preference shares (Nos. 16,640 to 40,000) of the *United River Plate Telephone Co. (Ltd.)*, and the securities have also been ordered for quotation in the official list. The committee has also been asked to appoint a special settling day in 20,000 vendors' ordinary £1 fully-paid shares (Nos. 27,001 to 47,000) of Messrs. *Davis and Timmins (Ltd.)*, and also the further issue of 10,000 ordinary £5 shares (Nos. 90,001 to 100,000) and 10,000 6 per cent. cumulative preference £5 shares (Nos. 70,001 to 80,000) of Messrs. *Willans and Robinson (Ltd.)*

Digitized by Google

WESTERN UNION TELEGRAPH CO.—This company have issued their report for the quarter ended Sept. 30, 1900. The following statement, dated Sept. 12, shows the condition of the company at the close of the quarter ended June 30, 1900:—

Surplus April 1, 1900, as per last quarterly report ...		$8,298,224 26
Net revenues, quarter ended June 30, 1900		1,600,925 75
From which deducting for—		$9,899,150 01
Dividend of 1½ per cent. paid July 16	$1,217,000 00	
Interest on bonded debt.....	223,945 15	
		1,440,945 15
Left a surplus July 1, 1900, of		$8,458,204 86
The net revenues of the quarter ending Sept. 30, based upon nearly completed returns for July, partial returns for August, and estimating the business for Sept. will be about		1,600,000 00
From which appropriating for—		$10,058,204 86
Interest on bonded debt		239,040 00
		$9,819,164 86
It requires for a dividend of 1½ per cent. on capital stock issued, about		1,217,000 00
Deducting which leaves a surplus, after paying dividend, of		$8,602,164 86

In view of the preceding statements, the committee recommend that a dividend of 1½ per cent. on the capital stock of the company be declared payable on and after the 15th inst.
